COMMERCIAL SUPPORT

In the interest of objective, balanced, and scientifically rigorous activities, the IAS–USA seeks grant support from multiple commercial companies, particularly from companies with competing products. These companies have no input in or control over the selection of faculty or content of the presentations.

CROI 2014 has received grant support commitments from the following commercial companies:

Platinum

![Merck](image1)
![ViiV Healthcare](image2)

Gold

![Bristol-Myers Squibb](image3)
![Janssen](image4)

Silver

![Abbvie](image5)
![Gilead](image6)
![Salix Pharmaceuticals, Inc.](image7)

Additional support has been provided by Mylan, Inc.

**Auditorium**
Overview

The 2014 Conference on Retroviruses and Opportunistic Infections (CROI) will be held at the John B. Hynes Veterans Memorial (Hynes) Convention Center from March 3 to 6, 2014. CROI was established in 1993 to provide a forum for basic scientists and clinical investigators to present, discuss, and critique their investigations into the epidemiology and biology of human retroviruses and associated diseases. The synergy of basic science and clinical investigation has been a major contributor to the success of the meeting. CROI is the preeminent HIV research meeting in the world and attracts more than 4000 HIV/AIDS research leaders internationally. The goal of the conference is to provide a forum for researchers to translate their laboratory and clinical findings into tangible progress against the HIV pandemic. CROI has facilitated the presentation of important discoveries in the field, thereby ultimately accelerating progress in HIV/AIDS research.

Americans with Disabilities Act

CROI 2014 endeavors to fully comply with the legal requirements of the Americans with Disabilities Act (ADA). If you require assistance onsite, please visit the Attendee Services booth on the Plaza level during the conference.

CROI Foundation

The CROI Foundation is a not-for-profit organization that operates exclusively for the charitable and educational purpose of organizing, promoting, and presenting the Conference on Retroviruses and Opportunistic Infections (CROI). The CROI Foundation appoints the members of the Program Committee, the Committee is responsible for the scientific content of the conference.

The CROI Foundation Board of Directors

Constance A. Benson, MD, President
University of California San Diego
San Diego, CA, United States

John M. Coffin, PhD, Secretary-Treasurer

Robert T. Schooley, MD
University of California San Diego
San Diego, CA, United States

Mario Stevenson, PhD
University of Miami
Miami, FL, United States

IAS–USA

The International Antiviral (formerly AIDS) Society–USA (IAS–USA) is a 501(c)(3) not-for-profit professional education organization. The IAS–USA serves as the CROI 2014 Conference Secretariat.

The mission of the IAS–USA is to improve the treatment, care, and quality of life for people with HIV, hepatitis C virus, or other viral infections through high-quality, relevant, balanced, and needs-oriented education and information for practitioners who are actively involved in medical care.
Continuing Medical Education (CME)

Accreditation Statement

The International Antiviral Society—USA (IAS—USA) is accredited by the Accreditation Council for Continuing Medical Education to provide continuing medical education for physicians.

The IAS—USA designates this live activity for a maximum of 27.50 AMA PRA Category 1 Credits™. Physicians should claim only the credit commensurate with the extent of their participation in the activity.

Since 2006, the IAS—USA has had Accreditation with Commendation, being a member of an elite group of organizations in the United States that have been awarded this prestigious status, which is, in the words of the ACCME, “reserved for programs that are truly exceptional.”

Objectives

After participating in CROI 2014, learners will be able to:

• Describe current basic science research on the pathogenesis of HIV and advances toward a cure
• Discuss the most recent findings from clinical trials in the HIV field and the implications of these data for state-of-the-art treatment strategies
• Review current epidemiologic data on the prevalence of HIV infection, transmission, treatment, and linkage to and retention in care in populations worldwide and discuss the implications of these data for public health program planning

Statement of Need

Since HIV was identified, the scientific response to the global pandemic has been a coordinated effort among basic researchers, clinical investigators, health care providers, epidemiologists, and community leaders to move information and potential treatment options from research to clinical trials and out to affected communities as quickly as possible. CROI was founded in 1993 by research investigators working in HIV/AIDS and its complications as a science-focused forum for exchanging current research findings among their international peers. CROI continues to focus on scientific exchange, providing an environment in which basic science researchers, translational researchers, clinical investigators, epidemiologists, and public health experts meet to present and discuss the latest research on different facets of HIV and its complications.

CME Credit Information

Physicians (MD, DO, and international equivalents) are eligible to receive continuing medical education (CME) credit for participation in the 2014 Conference on Retroviruses and Opportunistic Infections (CROI). Other practitioners and clinicians can receive a Certificate of Participation verifying their attendance as required by the American Medical Association (AMA).

Claiming CME Credits or a Certificate of Participation

During the conference, daily evaluations will be emailed to all CROI participants, to the account they used to register for the conference. On March 7, 2014, all CROI participants will receive a final email that will contain their registration confirmation number and a link to the overall CROI evaluation. To obtain CME Credits or a Certificate of Participation for CROI, this final evaluation must be completed by Friday, March 21. Once the evaluation is submitted, participants will receive the link to claim and print their certificate.

To determine the number of CME credits or hours that you can claim, calculate your time spent attending the conference, including plenary sessions, symposia, themed discussions, etc. For example, if you attended 2 plenary talks (8:30 am to 9:30 am), a themed discussion (1:30 pm to 2:30 pm), and a symposia (4:00 pm to 6:00 pm), you would have a total of 4 hours to apply towards your credits. At the end of CROI please add together the hours from the entire conference for your certificate. You may claim a maximum of 27.50 AMA PRA Category 1 Credits™ for this activity.

Faculty Financial Disclosure

It is the policy of the IAS—USA to ensure balance, independence, objectivity, and scientific rigor in all its educational activities. All faculty members (speakers, presenters, moderators, conveners, etc) participating in IAS—USA-sponsored activities are required to disclose to the program audience any financial interests within the past 12 months that could be perceived to influence, or give the appearance of potentially influencing, the written or oral presentation. (The ACCME defines a financial interest as an interest in any amount.) The information is intended to make our audience aware of author/ contributor interests and commitments with commercial companies or other entities so that they may form their own judgments about such associations.

Each author or contributor is required to complete this financial disclosure declaration. In accordance with IAS—USA policy, the IAS—USA will identify and resolve ahead of time any possible conflicts of interest that may influence CME activities with regard to exposition or conclusion.

Drug and Product Disclaimer

This activity may contain information about the investigational uses of drugs or products that are not approved by the US Food and Drug Administration. Please consult full prescribing information before using any medication or product mentioned in this activity.

Welcome Reception

Please join us after the opening session, Monday, March 3, for an attendee welcome reception at the Hynes Convention Center. Light hors d'oeuvres and refreshments will be served. The reception will be held March 3 in Hall C.
General Information

Meals

Morning coffee breaks and afternoon snack breaks will be available to conference registrants in the Poster Hall. Outtakes Express concession stand on Level 2, will be open from 9 AM to 1:30 PM Tuesday through Thursday. The Outtakes Express stand will have cold items for purchase such items as wraps, sandwiches, salads, snacks, and chips as well as beverages. Attendees are on their own for lunch during the hours of approximately 12 noon to 1:30 PM each day. Below is a list of food service options located in the Convention Center or within a short walking distance.

At the Convention Center
Towne Stove and Spirits The Capital Grille

At the Prudential Center
(next to the South Lobby main entrance of the Convention Center)
5 Napkin Burger Au Bon Pain
Ben & Jerry’s Boston Chowda Co
California Pizza Cheeseboy
Cheesecake Factory Dunkin’ Donuts
Flamers Godiva
Gourmet India Haru
Legal Sea Foods Panda Express
Paradise Bakery PF Chang’s
Pizzeria Regina Poulet
Qdoba Sarku Japan
Paradise Bakery PF Chang’s
Pizzeria Regina Sarku Japan
Qdoba Sarku Japan
Top of the Hub Wagamama

At the Sheraton Boston
(next to the South Lobby main entrance of the Convention Center)
SideBar & Grille Starbucks
Café Apropos

At the Marriott Copley, Copley Place Mall, and Westin Copley Place
(within 1 block of the Convention Center)
Bar 10 Champion’s Sports Bar
The Huntington Legal Sea Foods
The Palm Turner Fisheries
Starbucks Osushi

Overflow Accommodations for Session Rooms

Most session rooms will have designated overflow areas. Should any session draw substantially higher attendance than can be accommodated, a nearby space will be available to provide a live audio and video feed.

USB Flash Drive

Each participant was supplied a blank 4Gbyte USB flash drive upon badge pickup. The 2014 Program at a Glance and Agenda and Abstracts Book are available online to be loaded on to the USB flash drive. Downloads can be completed at the Cyber Cafe or directly from the conference website.

Website

For additional information about the conference please visit the website at www.CROI2014.org

Webcasts and Podcasts

Plenaries, symposia, scientific overviews, oral abstract sessions, and themed discussions will be webcast and podcast. Attendees who ask questions during these presentations should understand that their questions will be included in the webcast and podcast and as such grant permission. Webcasts are also available as streaming video for the Apple iPad and iPhone. Visit www.CROI2014.org or www.CROIwebcasts.org to access the CROI 2014 webcasts and podcasts. Webcasts will be available within 24 hours of the end of the session.

WiFi Access at the Conference

Complimentary WiFi access is provided at the Hynes Convention Center. There are 2 network options:
- Hynes Wireless
- Hynes Wireless Fast (only for recent models of smart phones and tablets)
There is no login information required.

Badges

Badge pickup will be available at the registration lobby; please bring photo identification that clearly shows your name. You must wear your name badge to gain entry to all official meeting activities, including the poster sessions.

DO NOT LOSE OR FORGET TO BRING YOUR BADGE. Payment of an additional registration fee ($730) will be required to replace a lost badge.

New Mothers/Lactation Room

CROI has provided New Mothers/Lactation Rooms for nursing mothers. These rooms are located on the 3rd floor in rooms 307 and 308.

Child Care

Children are not permitted entry into any meeting room, including the poster area. If you should require child care, please contact the concierge of your hotel.

Conference Etiquette

Please ensure all cell phones and pagers are off or are placed in SILENT mode.

No flash photography is permitted in session rooms.

Abstract Content

Author names, institutions, abstract titles, and abstracts in the Program and Abstracts eBook are presented as submitted by the corresponding author.

Abstract Review Process

The Scientific Program Committee and a panel of external reviewers reviewed the more than 1900 submitted abstracts. Each abstract was scored by 4 to 10 reviewers selected for each abstract category based upon their individual expertise.

OC and SC members were instructed to review the abstracts for the quality and originality of the work and to score them numerically. All reviewers were instructed to abstain from scoring any abstract on which they are an author/co-author, have a financial or personal conflict of interest, or do not have the appropriate expertise to evaluate.

Scores for each abstract are averaged and the standard deviation is calculated to assess variability. If variability is high, outlier scores are identified and censored. Abstracts with high variability in scores are discussed individually during a series of conference calls.

Common Reasons for Abstract Rejection

- Information is not new enough
- Methodology is inadequate or insufficient to support conclusions
- Background does not summarize the hypothesis; submission is poorly written
- Abstract is duplicative of other submissions
- Inappropriate for CROI
- Controls are absent or inadequate
- Statistical evaluation is inadequate or absent
- Summary of essential results is inadequate or absent
- Data are inadequate or insufficient to support conclusions
- Submission reports clinical trial and data from unplanned analysis or incomplete or ongoing studies
- Format does not follow guidelines (eg, section[s] missing, more than 1 graphic, table, or figure submitted)

- North America 1161 54%
**Emargo Policy**

**General**

The research presented at CROI 2014 is embargoed until the conclusion of the session in which it is presented. For example, if a study is presented from 2:15 PM to 2:30 PM, as part of a session that ends at 3:00 PM, the embargo on that study lifts at 3:00 PM. Embargoes on poster presentations lift at the conclusion of the session in which the poster is presented. If a study to be presented at CROI 2014 is included in an official CROI press conference and that press conference takes place before the official presentation of the study at the conference, the embargo lifts at the conclusion of the press conference in which that study is featured.

**Social Media**

CROI embargo policies apply to any public dissemination of research information presented at the conference, including through electronic publication (eg., blogs) or social media (eg., Facebook, Twitter). No public dissemination of research information from the conference is permitted prior to the lifting of the conference embargo.

Individuals or organizations that violate the conference embargo policy may have their conference credentials revoked, and may not be permitted to participate in future conferences.

MONDAY MARCH 3, 2014

Session W1 Workshop
9:00 AM – 1:15 PM  Ballroom B/C
Program Committee Workshop for New Investigators and Trainees

Target audience: This workshop is directed toward new trainees (eg, undergraduate students, graduate students, postdoctoral fellows, and physician fellows) and new investigators (both international and domestic).

Level of knowledge: It is assumed that learners have been conducting active research in the field for less than 3 years.

Objectives: At the completion of the workshop, learners will be able to:
• Recognize the major areas of HIV investigation being presented at the conference
• Identify the top 3 to 5 research questions in the field of retroviruses and opportunistic infections today
• Describe some of the proposed solutions for addressing the challenges presented globally by a variety of retroviruses and opportunistic infections

Conveners:
Judith S. Currier, University of California Los Angeles, Los Angeles, CA, United States
John W. Mellors, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States

1  HIV Pathogenesis: Current Understanding and Future Research
   Dana H. Gabuzda, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, United States

2  HIV Cure Research
   John W. Mellors, University of Pittsburgh, Pittsburgh, PA, United States

3  HIV Vaccine Immunology: Recent Progress and Continuing Challenges
   Richard A. Koup, Vaccine Research Center, National Institute of Allergy and Infectious Disease, National Institutes of Health, Bethesda, MD, United States

4  HIV Prevention Research: Progress and Challenges
   Sharon L. Hillier, University of Pittsburgh School of Medicine, Magee-Womens Hospital, Pittsburgh, PA, United States

5  Pathogenesis and Control of HCV Infection
   David L. Thomas, The Johns Hopkins University School of Medicine, Baltimore, MD, United States

Session MD Panel
1:30 PM – 2:30 PM  Ballroom B/C
6  Martin Delaney Panel: Hepatitis C Virus: From Trials and Tribulations To Triumph

The Martin Delaney Panel is held annually during the workshops for Young pioneering HIV/AIDS activist Martin Delaney (1945-2009). It recognizes the important contributions of community advocacy and engagement to research.

Panel Leaders
Jeff Taylor, AIDS Treatment Activists Coalition, Palm Springs, CA, United States
Tracy Swan, Treatment Action Group, New York, NY, United States

Panelists
Isabelle Andrieux-Meyer, Médecins sans Frontieres, Geneva, Switzerland
Jules Levin, National AIDS Treatment Advocacy Project (NATAP), New York, NY, United States
Lynn E. Taylor, Brown University, Providence, RI, United States

Session W2 Workshop
2:30 PM – 4:30 PM  Ballroom B/C
Clinical Trial Design and Analysis

Target audience: This session is directed to clinicians and scientists who are interested in designing or interpreting clinical trial results.

Level of knowledge: It is assumed that learners are familiar with the basic design of randomized and observational clinical studies.

Objectives: At the completion of the session, learners will be able to:
• Discuss one or more possible solutions to adherence challenges
• Define factorial designs and discuss their advantages and disadvantages
• Define meta-analyses and discuss their advantages and disadvantages

Conveners:
Susan Buchbinder, San Francisco Department of Public Health, San Francisco, CA, United States
Richard Chaisson, The Johns Hopkins University School of Medicine, Baltimore, MD, United States

7  Adherence: The Achilles Heel for Trial Interventions
   David R. Bangsberg, Massachusetts General Hospital Center for Global Health, Boston, MA, United States

8  Studying Multiple Interventions: Factorial Designs and Other Approaches
   Richard J. Hayes, London School of Hygiene and Tropical Medicine, London, United Kingdom

9  So Many Trials, So Little Time: Meta-Analysis Do's and Don’ts
   Dean A. Follmann, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States
Oral Sessions

Session W3 Workshop
2:30 PM – 4:30 PM  Ballroom A

Frontiers in Laboratory Science Workshop

The purpose of this workshop is to present the main technological and conceptual developments in life sciences that are influencing HIV research or hold a significant potential for research. The presentation should educate and engage investigators and clinicians, and spark interest in emerging technologies. The workshop format is designed to provide in-depth views on technologies that define B and T cell development and characterization, progress in the study of host-pathogen interactions at molecular and cellular levels, and new approaches to genetic editing. Applications in HIV research will be discussed.

Conveners
Galit Alter, Ragon Institute of Massachusetts General Hospital, Massachusetts Institute of Technology, and Harvard, Cambridge, MA, United States
Amalio Telenti, Institute of Microbiology, University of Lausanne, Lausanne, Switzerland

10 Systems Immunology Approaches for Vaccine Profiling and Antibody Discovery
Sai Reddy, Swiss Federal Institute of Technology Zurich, Basel, Switzerland

11 3-D Structural Analysis of HIV Using Correlative CryoEM and Live Cell Imaging
Peijun Zhang, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States

12 Virus-Host Interactions Revealed Through Proteomics/Phosphoproteomics
Beatriz Ueberheide, New York University Langone Medical Center, New York, NY, United States

13 CRISPRs and Other Genome Editing Systems
Paul F. Bates, University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA, United States

Session W4 Workshop
2:30 PM – 4:30 PM  Room 304

Workshop for Clinicians Who Are New To Hepatitis C Management: A Case-Based Interactive Session

Target audience: This session is directed to persons newly engaged in the care of HCV-infected patients

Level of knowledge: It is assumed that learners are familiar with fundamental principles of medicine and antimicrobial therapy

Objectives: At the completion of the session, learners will be able to:
• List the practices routinely required for HCV-infected persons with cirrhosis
• Describe patients for whom HCV treatment is not currently advisable
• List the recommended therapies for persons with genotypes 1-4 HCV infection

Conveners
David L. Thomas, The Johns Hopkins University School of Medicine, Baltimore, MD, United States
Robert T. Schooley, University of California San Diego, San Diego, CA, United States

14 Liver Management
Kenneth E. Sherman, University of Cincinnati College of Medicine, Cincinnati, OH, United States

15 Interactive Case Presentations
David L. Wyles, University of California San Diego, San Diego, CA, United States
Susanna Naggie, Duke Clinical Research Institute, Durham, NC, United States

Opening Session
5:00 PM – 7:00 PM  Auditorium

Welcome

Session NL1 Lecture
Bernard Fields Lecture

The Bernard Fields Lecture, named in tribute to the exemplary work of the esteemed microbiologist and virologist Bernard Fields, is given during the opening session, to recognize the speaker for their important and relevant contributions to the fields of virology and viral pathogenesis.

17 Making and Breaking Barriers To Cross-Species HIV-1 Transmission
Paul D. Bieniasz, Aaron Diamond AIDS Research Center, The Rockefeller University, New York, NY, United States

Session NL2 Lecture
N’Galy-Mann Lecture

The N’Galy-Mann Lecture, named in honor of Drs Bosenge N’Galy and Jonathan Mann for their pioneering work in HIV science in Africa, is given during the opening session and recognizes an HIV/AIDS researcher for his or her important and relevant work in the fields of epidemiology or clinical research.

18 Application of Scientific Knowledge and Evidence To Limit the Progression of HIV/AIDS and Fight Other Endemic Diseases in West Africa
Souleymane Mboup, Centre Hospitalier Universitaire Aristide le Dantec, Dakar, Senegal

Welcome Reception
7:00 PM – 9:00 PM  Hall C

Please join us after the opening session, Monday, March 3, for an attendee welcome reception at the Hynes Convention Center. Light hors d’oeuvres and refreshments will be served.
Tuesday, March 4, 2014

Session 01 Oral Abstracts

10:00 AM – 12:15 PM Ballroom B/C

Hepatitis

Moderators

Jürgen Rockstroh, University Hospital Bonn, Bonn, Germany
Kristen M. Marks, Weill Cornell Medical College, New York, NY, United States

21 Longitudinal Phenotypic Profiling of Early HCV-Specific CD4 T Cells in HIV- and HCV+ Individuals

1Gastrointestinal Unit, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, 2Infectious Disease Division, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, 3Laboratorio de Hepatites Virales, Instituto Oswaldo Cruz, Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil, 4Bersanya Research Institute at Virginia Mason, Seattle, WA, United States

22 Rapid Peripheral In Vivo Cellular Changes During Interferon-Free Treatment of Hepatitis C

Eric G. Meissner, Brian Sartich, Yu-Jin Lee, Olga Prokunina, Anuoluwapo Osinusi, Anita Kohli, Henry Masur, Susan Mor, Shyamandas Haddi, Shyamasundaran Kadam

1Laboratory of Immunoregulation, NIAID/NIH, Bethesda, MD, United States, 2SAC-Frederick, Inc, Frederick, MD, United States, 3CCMD/NIH, Bethesda, MD, United States

23 Faldaprevir Plus Pegylated Interferon Alfa-2a/Ribavirin in HIV/HCV Coinfection: STARTVerso4

Douglas Dieterich, Cristina Tural, Mark Nelson, Keikawus Arastéh, Vicente Soriano, Josep Guardiola, Sanjay Bhagani, Jürgen K. Rockstroh, Jerry O. Stern, Anne-Marie Quinson

1Mount Sinai Medical Center, New York, NY, United States, 2Mount Sinai Hospital, New York, NY, United States, 3Mount Sinai School of Medicine, New York, NY, United States, 4Mount Sinai School of Medicine, New York, NY, United States, 5Mount Sinai School of Medicine, New York, NY, United States

25 All-Oral Combination of Daclatasvir, Asunaprevir, and BMS-791325 for HCV Genotype 1 Infection

Gregory T. Everson, Paul J. Thuluvath, Eric Lawitz, Tarek Hassanein, Maribel Rodriguez-Torres, Trevor Hawkins, Vinod Rustgi, Frederico Hinestrosa, James Levin, Karen Sims

1University of Colorado Denver, Aurora, CO, United States, 2Mercy Medical Center, Baltimore, MD, United States, 3The Texas Liver Institute, University of Texas Health Science Center, San Antonio, TX, United States, 4Southern California Liver Centers, Coronado, CA, United States, 5Fundacion de Investigacion, San Juan, Puerto Rico, 6Southwest CARE Center, Santa Fe, NM, United States, 7Metropolitan Research, Arlington, VA, United States, 8Orlando Immunology Center, Orlando, FL, United States, 9Dean Foundation for Health, Research and Education, Inc, Madison, WI, United States, 10Bristol-Myers Squibb, Hopewell, NJ, United States

27LB Combination Oral, Hepatitis C Antiviral Therapy for 6 or 12 Weeks: Final Results of the SYNERGY Trial

Anita Kohli, Zayani Sims, Amy Nelson, Aru Osinusi, Geb Tefari, Phi Pang, William Symonds, John Mitchcllison, Henry Masur, Shyam Kottlow

1Critical Care Medicine Department, National Institutes of Health, Bethesda, MD, United States, 2Clinical Research Directorate/Clinical Monitoring Research Program, Leidos Biomedical Research, Inc. (formerly SAIC–Frederick, Inc.), Frederick National Laboratory for Cancer Research, Frederick, MD, United States, 3Laboratory of Immunoregulation, National Institutes of Health, Bethesda, MD, United States, 4University of Maryland, Baltimore, MD, United States, 5Unity Health Care, Washington, DC, United States, 6Gilead Sciences, Foster City, CA, United States

28LB Daclatasvir in Combination With Simprevir ± Ribavirin for Hepatitis C Virus Genotype 1 Infection

Stefan Zeuzem, Christophe Hezode, Jean-Pierre P. Bronowicki, Veronique Loustad-Ratti, Francisco Gea, Maria Barti, Maria Beumont-Maurié, Navdeep Boparai, Gaston Picchio, Stephanie Noviello, on behalf of the LEAGUE-1 Study Team

1JW Goethe University Hospital, Frankfurt a.m., Germany, 2Hopital Henri Mondor, Paris, France, 3Centre Hospital Universitare de Nancy, Vandoeuve Les Nancy, France, 4Universite Lirmoges, Limoges, France, 5University Hospital La Paz, Madrid, Spain, 6Hospital Vall Hebron, Barcelona, Spain, 7Janssen Infectious Disease BVVA, Beerse, Belgium, 8Bristol-Myers Squibb, Princeton, NJ, United States, 9Janssen Research and Development, Titusville, NJ, United States

29LB PEARL III: SVR ≥99% After 12 Weeks of ABT-450/rl/267 + ABT-333 ± RBV in Treatment Naive HCV GT1b Infection

Peter Ferenci, Anders Nyberg, David Bernstein, Yaacov Baruch, Vladimir Chulanov, Wangang Xie, Daniel Cohen, Thomas Podesadcik, K Rajender Reddy, on behalf of the PEARL-III Study Group

1Universitätsklinik fuer Innere Medizin Il, Vienna, Austria, 2Kaiser Permanente, San Diego, CA, United States, 3North Shore University Hospital, Manhasset, NY, United States, 4Rambam Health Care Campus, Haifa, Israel, 5Federal Budget Institute of Science, Moscow, Russian Federation, 6AbbVie Inc., North Chicago, IL, United States, 7University of Pennsylvania, Philadelphia, PA, United States
30 Early Antiretroviral Therapy Appears To Normalize Intrathecal Markers of Immune Activation

Julia Peterson1, Evelyn Lee1, Dietmar Fuchs1, Richard W. Price1, Serena Spudich1
1Neurology, University of California San Francisco, San Francisco, CA, United States, 2Innsbruck Medical University, Innsbruck, Austria, 3Neurology, Yale University, New Haven, CT, United States

31 Immediate Antiretroviral Therapy Mitigates the Development of Neuronal Injury in Acute HIV

Michael J. Peluso1, Victor Valcour2, Jintanat Ananworanich3, 4, Pasiri Sithanamsuwan4, Thep Chalermbhat5, Nithya Chomchey5, Bonnie Slik6, Magnus Gissler7, Henrik Zetterberg7, Serena Spudich4, on behalf of the RV144/SEARCH 010 and 011 Study Teams

32 Replication of HIV-1 in the Central Nervous System of Adults Early After Infection

Christa Buckheit Sturdevant1, Gretja Schnell1, Richard W. Price2, Serena Spudich1, Ronald Swanstrom3
1UNC Chapel Hill, Chapel Hill, NC, United States, 2University of California San Francisco, San Francisco, CA, United States, 3Yale University School of Medicine, New Haven, CT, United States

33 Persistent CSF, But Not Plasma HIV RNA Is Associated With Increased Risk of New-Onset Depression

Edward R. Hammond1, Rosa M. Crum1, Glenn J. Treisman1, Shruti H. Mehta1, Ronald J. Ellis1, Igor Grant1, Scott L. Letendre1, Christina M. Marra1, Susan Morgello1, Justlin C. McArthur1
1The Johns Hopkins University, Baltimore, MD, United States, 2University of California San Diego, San Diego, CA, United States, 3University of Washington, Seattle, WA, United States, 4Cahn School of Medicine at Mount Sinai, New York, NY, United States

34 CSF Metabolomics Reveals Altered Waste Clearance and Accelerated Aging in HIV Patients WITH HAND

Edana Cassoff1, Vikas Misra1, Anupriya Dutta1, Susan Morgello2, Dana Gabuzda2
1Cancer Immunology and AIDS, Dana-Farber Cancer Institute, Boston, MA, United States, 2The Mount Sinai Medical Center, New York, NY, United States

35 Cerebral Small Vessel Disease and HAND in ARV-Treated Subjects

Virawuth Soontornvyomkij1, Anya Ulauf1, Benchawana Soontornvyomkij1, Ben Gousau1, Will Toperoff2, David J. Moore2, Elezor Masiclish1, Igor Grant1, Cristian L. Achim1
1UC San Diego, San Diego, CA, United States

Session 0-3 Oral Abstracts

10:00 AM – 12:30 PM Ballroom A

Prevention and Epidemiology: Evolving Trends

Moderators
Rochelle P. Walesky, Harvard Medical School, Massachusetts General Hospital, Boston, MA, United States
Ian M. McGowan, University of Pittsburgh, Pittsburgh, PA, United States

36 Temporal Trends in Prognostic Markers of HIV-1 Virulence and Transmissibility

Nikos Pantazis1, Kholoud Porter1, Dominique Costagliola2, Andrea De Luca1, Jade Ghosn2, Marguerite Guiguert3, Anthony D. Kelleher1, Charles Morrison1, Rodolphe Thiébaut1, Giota Touloumi4, on behalf of the CASCADE Collaboration in EuroCoord
1Hygiene Epidemiology & Medical Statistics, Athens University Medical School, Athens, Greece, 2MRC Clinical Trials Unit at University College London, London, United Kingdom, 3INSERM U943, Université Pierre et Marie Curie - Paris 6, UMR S 943, Paris, France, 4Institute of Clinical Infectious Diseases, Università Cattolica del Sacro Cuore, Roma, Italy, 5Internal Medicine and Infectious Diseases, Bicêtre University Hospital, Kremlin Bicêtre, Paris, France, 6Kirby Institute, University of New South Wales, Sidney, Australia, 7HIV 360, Durham, NC, United States, 8INSERM U943 Centre of Epidemiology and Biostatistics, ISPED Bordeaux School of Public Health, University Bordeaux Segalen, Bordeaux, France

37 Transmission Clusters, Recent Infection and STIs Among New HIV Cases: Implications for Prevention

Hong-Ha M. Truong1, 2, Sharon Pipkin3, Kara O’Keefe1, Brian Louie1, Teri Liegler2, Willi McFarland1, 3, Robert M. Grant1, 2, Mark Pandori3, Kyle Bernstein1, Susan Scheer3
1University of California San Francisco, San Francisco, CA, United States, 2Gladistone Institute of Virology and Immunology, San Francisco, CA, United States, 3Department of Public Health, San Francisco, CA, United States

38 Race and Age Disparities in HIV Incidence and Prevalence Among MSM in Atlanta, GA

Eli S. Rosenberg1, Patrick S. Sullivan1, Colleen F. Kelley1, Travis H. Sanchez1, Nicole Luisi1, Carlos del Rio2, Laura F. Salazar1, Paula F. Frew1, John L. Peterson1

924 Greater Virologic Control in Infants Initiated On ART Before 6 Months of Age
Stephanie Shiah1, Ashraf Coovadia2, Karl-Gunter Technau3, Renate Strehlau1, Leigh Martens1, Françoise Pinillos1, Elaine J. Abrams1, Louise Kuhn3
1Columbia University, New York, NY, United States, 2University of the Witwatersrand, Johannesburg, South Africa

925 Early Viral Suppression Improves Neurocognitive Outcomes in HIV-Infected Children
Claudia S. Crowell1, Yanling Hu2, Katherine Tassiopoulos2, Kathleen M. Male1, Ram Yog2, Rohan Hazra3, Richard M. Butstein1, Sharon L. Nicholes1, Renee A. Smith1, William J. Muller1, for the IMMPACT 219C Study Team and the PediatricHIV/AIDS Cohort Study
1Pediatrics, University of Washington, Seattle, WA, United States, 2Epidemiology, Harvard School of Public Health, Boston, MA, United States, 3Northwestern University Feinberg School of Medicine, Chicago, IL, United States, 4National Institute of Child Health and Human Development, Bethesda, MD, United States, 5Children’s Hospital of Philadelphia, Philadelphia, PA, United States, 6University of California San Diego, La Jolla, CA, United States, 7University of Illinois at Chicago, Chicago, IL, United States

926 Early Cytomegalovirus Viraemia and Clinical Outcomes of HIV-Infected Children in the Early ART Era
Nei-juan Hsiao1, 2, 3, Kennedy Otowombo2, Landon Myer2, Avy Violar1, Diana Gibb1, Ravindra Panchia1, Abdel Babiker1, Patrick Jean-Philippe1, Mark Fredric Cotton
1Clinical Laboratory Sciences, University of Cape Town, Cape Town, South Africa, 2Perinatal HIV Research Unit, Johannesburg, South Africa, 3Public Health and Family Medicine, University of Cape Town, Cape Town, South Africa, 4Medical Research Council UK, London, United Kingdom, 5National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, 6Paediatrics and Child Health, Stellenbosch University, Cape Town, South Africa

Session TDS Themed Discussion
1:30 PM – 2:30 PM Room 311
Treatment Cascade and Loss To Follow-Up
Discussion Leader
David R. Bangsberg, Massachusetts General Hospital Center for Global Health, Boston, MA, United States

1060 Comparative Effectiveness of HIV Care and Treatment Programs in East Africa
Elvin Geng1, Thomas Odeny2, Rita Lyamuya3, Alice Nakwigogwa-Muwangwa4, Mwebesa Bwana5, Paula Braithstein6, Andrew Kambugu7, Elizabeth Bukusi1, Geoffrey Somi8, Lameck Diero9, Jeffrey Martin10
1Medicine, University of California San Francisco, San Francisco, CA, United States, 2KEMRI, Nairobi, Kenya, 3Medicine, NACP, Dar es Salaam, Tanzania, 4Centre for HIV and STIs, National Institute for Communicable Diseases, Johannesburg, South Africa, 5Clinical Trials Unit, Medical Research Council, London, United Kingdom, 6Paediatrics and Child Health, Stellenbosch University, Cape Town, South Africa, 7Medicine, MUST, Mbarara, Uganda, 8AMPATH, Eldoret, Kenya, 9Medicine, KEMRI, Nairobi, Kenya, 10NACP, Dar es Salaam, Tanzania, United Republic of, 11PAMPATH, Eldoret, Kenya, 12University of California San Francisco, San Francisco, CA, United States

1063 HIV Care Cascade Among Hard To Reach Populations in India: Need To Expand HIV Counseling and Testing
Shruti H. Mehta1, Gregory M. Lucas2, Sunilti Solomon2, Aylur K. Srikrishnan3, Allison McFall4, P. Nandagopali5, Pachamuthu Balakrishnan6, Muniratham S. Kumar1, David D. Celentano2, Sunil S. Solomon3, 2
1Epidemiology, The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, 2The Johns Hopkins University School of Medicine, Baltimore, MD, United States, 3YR Gaonlone Centre for AIDS Research and Education, Chennai, India

1061 Loss To Follow-up: Determining Outcomes for Adults Enrolled in HIV Services in Kenya
William Reidy1, Mansi Agarwal2, Matthew Lamb3, Mark Hawken4, Duncan Chege1, Batya Euli1, Elaine J. Abrams5, Elvin Geng6
1Mailman School of Public Health, ICAP-Columbia University, New York, NY, United States, 2School of Medicine, University of California at San Francisco, San Francisco, CA, United States

1064 Unplanned Interruptions in HIV Care in Nigeria: Rates and Implications
Aima A. Ahonkhai1, Bolanle Banigbe2, Juliet Adeola2, Ifeyinwa Omwuatu2, Ingrid V. Bassett3, Elena Losina4, Kenneth A. Freedberg1, Prosper Okonkwo1, Susan Regan1
1Massachusetts General Hospital, Boston, MA, United States, 2AIDS Prevention Initiative Nigeria, Abuja, Nigeria, 3Infectious Disease, Massachusetts General Hospital, Boston, MA, United States, 4Brigham and Women’s Hospital, Boston, MA, United States

1065 Using the Side Door: Non-Linear Patterns Within the HIV Treatment Cascade in Zambia
Charles B. Holmes1, 2, Angela Bengston1, 2, Izukarji Sikazwe3, 2, Carolyn Bolton-Moore4, 1, Lloyd B. Mulenga1, Patrick Musonda1, 3, Benjaminii H. Chi2
1Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, 2University of North Carolina School of Medicine, Chapel Hill, NC, United States, 3University of East Anglia, East Anglia, United Kingdom
Session S1 Symposium
4:00 PM – 6:00 PM | Ballroom B/C
Toward a Cure: A Challenging Game of Hide and Seek

Target audience: This session is directed to clinicians, basic researchers, and affected persons interested in the latest developments in HIV cure research.

Level of knowledge: It is assumed that learners are familiar with basic aspects of HIV replication and latency as well as standard therapeutic options.

Objectives: At the completion of the session, learners will be able to:
- Understand the effects of early treatment on the establishment of the latent reservoir
- Understand the roles of different T-cell subsets in maintaining the latent reservoir
- Describe how different animal models can be used to investigate cure strategies prior to clinical trials

Conveners
Christine Rouzioux, Université Paris Descartes, Paris, France
Hiroyu Hatano, University of California San Francisco, San Francisco, CA, United States

Impact of Early ART On HIV Eradication in Children
Katherine F. Luzuriaga
University of Massachusetts Medical School, Worcester, MA, United States

T Memory Stem Cells: The Stem Cell Reservoir for HIV?
Mathias Lichterfeld
Massachusetts General Hospital, Boston, MA, United States

Inflammation as an Obstacle for Remission:
Lessons Learned From Non-Human Primate Models
Michaela Müller-Trutwin
Institut Pasteur, Paris, France

Humanized Mouse Models for Studies On HIV Latency, Reservoirs, and Eradication Strategies
J. Victor Garcia-Martinez
University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Session S2 Symposium
4:00 PM – 6:00 PM | Ballroom A
HCV and Beyond

Target audience: This session is directed to clinicians and researchers interested in viral hepatitis, including the latest information on the epidemiology of HEV, the biology of HCV, and efforts to cure HCV and HBV infections.

Level of knowledge: It is assumed that learners are familiar with basic principles of virology, epidemiology, and immunology.

Objectives: At the completion of the session, learners will be able to:
- Recognize the nonhuman reservoirs for HEV infection
- Compare the innate immune responses to HCV and HIV infections
- Compare efforts to cure HIV and HBV infections
- Identify the major strategies for interferon alfa–sparing treatment of HCV
Session S3 Symposium
4:00 PM – 6:00 PM  Room 304
PrEP: Use It or Lose It

Target audience: This session is directed to clinicians and scientists who are interested in understanding the differences in pre-exposure prophylaxis (PrEP) trial results and how PrEP can best be implemented for populations at high risk of HIV acquisition.

Level of knowledge: It is assumed that learners are familiar with the current status of PrEP for HIV prevention, the results from major clinical trials, and the challenges associated with the success of PrEP.

Objectives: At the completion of the session, learners will be able to:

• Discuss potential reasons for differences in trial results
• Identify benefits and challenges in PrEP implementation in different settings
• Identify which populations may gain the greatest benefit from PrEP
Wednesday, March 5, 2014

Session PL3 Plenary
8:30 AM – 9:00 AM Auditorium

65 B-Cell Responses To HIV Infection: Challenges and Opportunities

Susan L. Moir, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

71 Lower Newborn Bone Mineral Content Associated With Maternal Use of Tenofovir Disoproxil Fumarate

1NICHHD, Maternal and Pediatric Infectious Disease Branch, NIH, Bethesda, MD, United States, 2Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, United States, 3Division of General and Community Pediatrics, Cincinnati Children’s Hospital Medical Center, Cincinnati, OH, United States, 4Department of Epidemiology, Harvard School of Public Health, Boston, MA, United States, 5Pediatric Endocrinology/Diabetology, Riley Hospital for Children at Indiana University, Indianapolis, IN, United States, 6Ann & Robert Lurie Children’s Hospital of Chicago, Chicago, IL, United States, 7Department of Pediatrics, Northwestern University Feinberg School of Medicine, Chicago, IL, United States, 8Department of Infectious Diseases, St. Jude Children’s Research Hospital, Memphis, TN, United States, 9Gerald J. and Dorothy R. Friedman School of Nutrition Science and Policy, Tufts University, Boston, MA, United States, 10Department of Pediatrics, University of Illinois at Chicago, IL, United States

Session PL4 Plenary
9:00 AM – 9:30 AM Auditorium

66 NeuroHIV in 2014: Beyond Dementia

Serena S. Spudich, Yale University, New Haven, CT, United States

72 Virologic Control by 1 Year of Age Significantly Reduces HIV-1 Reservoirs in Perinatal Infection

Deborah Persaud, Kunjal Patel, Brad Karalus, Carrie Ziemniak, Kaityn Rainwater-Lovett, Ya Chen, Douglas D. Richman, George K. Siberry, Russell VanDyke, Katherine Luzuriaga, Pediatric HIV/AIDS Cohort Study (PHACS) and IMPAACT Network

1Pediatrics, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, 2Epidemiology, Harvard School of Public Health, Boston, MA, United States, 3Pathology and Medicine, University of California San Diego, San Diego, CA, United States, 4Centre Kennedy Shriver National Institutes of Child Health and Human Development, Bethesda, MD, United States, 5Pediatrics, Tulane University Health Sciences Center, New Orleans, LA, United States, 6Pediatrics, University of Massachusetts Medical School, Boston, MA, United States

Session 0-5 Oral Abstracts
10:00 AM – 12:15 PM Room 304

Critical Issues in MTCT: Maternal Health and HIV Treatment in Children

Moderators

Amita Gupta, The Johns Hopkins University School of Medicine, Baltimore, MD, United States
A. Sarah Walker, Medical Research Council Clinical Trials Unit, London, United Kingdom

67 A 15-Year Review of Maternal Deaths in a Background of Changing HIV Management Guidelines

Coceka N. Mnyani, Eckhart Buchmann, Karlyn Frank, Helen Struthers, James McIntyre

1Anova Health Institute, Johannesburg, South Africa, 2University of the Witwatersrand, Johannesburg, South Africa

68 Incidence and Cofactors of Acute HIV During Pregnancy and Postpartum

John Kinuthia, Alison Drake, Daniel Matemo, Barbra Richardson, R. Scott McClelland, Grace John-Stewart

1Obstetrics and Gynecology, University of Nairobi, Nairobi, Kenya, 2Global Health, University of Washington, Seattle, WA, United States, 3Biostatistics, University of Washington, Seattle, WA, United States, 4Medicine, Global Health, Epidemiology, University of Washington, Seattle, WA, United States, 5Global Health, Epidemiology, Medicine, Pediatrics, University of Washington, Seattle, WA, United States

69 Efficacy and Safety of LPV/r Versus EFV in HIV+ Pregnant and Breast-Feeding Ugandan Women

Deborah Cohant, Paul Natureeba, Albert Plenty, Flavia Luweddde Julia Mwesawga, Veronica Ades, Edwin Charlebois, Tamara Clark Bridget Nzurubara, Moses Kamya, Pius Okong, Diane Havir

1OBYGN, University of California San Francisco, San Francisco, CA, United States, 2Infectious Diseases Research Collaboration, Kampala, Uganda, 3Medicine, University of California San Francisco, San Francisco, CA, United States, 4OBYGN, New York University, New York, NY, United States, 5Medicine, Makerere University, Kampala, Uganda, 6OBYGN, Makerere University, Kampala, Uganda

73 Virologic Efficacy of Efavirenz Maintenance Therapy in Neavirapine Prophylaxis-Exposed Children

Ashraf Coovadia, Elaine Abrams, Renate Streich, Stephanie Shiau, Françoise Philippe, Leigh Martens, Gillian Hunt, Wei-Yann Tsai, Lynn Morris, Louise Kuhn, NEVEREST 3 Study Team

1University of the Witwatersrand, Johannesburg, South Africa, 2Columbia University, New York, NY, United States, 3National Institute of Communicable Diseases, Johannesburg, South Africa

74LB Final Results of Koncert: A Randomized Noninferiority Trial of OD Vs BD LPV/r Dosing in Children

Hermione Lyall, KONCERT Trial Team

Imperial College London, London, United Kingdom

75LB Very Early Combination Antiretroviral Therapy in Perinatal HIV Infection: Two Case Studies

Deborah Persaud, Audra Devekis, Hannah Gay, Jagmohan Batra, Tempe Chen, David E. Michalik, Kaityn Rainwater-Lovett, Carrie Ziemniak, Katherine Luzuriaga, Yvonne Bryson

1Pediatrics, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, 2Pediatrics, Miller Children’s Hospital, Long Beach, CA, United States, 3Pediatrics, University of Mississippi Medical Center, Jackson, MS, United States, 4Pediatrics, University of Massachusetts Medical School, Worcester, MA, United States, 5Pediatrics, UCLA School of Medicine, Los Angeles, CA, United States

Université de Ouagadougou, Ouagadougou, Burkina Faso, 2Centre Munz, Bobo-Dioulasso, Burkina Faso, 3Department of Paediatrics and Child Health, Makerere University, Kampala, Uganda, 4School of Public Health, University of Western Cape, Cape Town, South Africa, 5Université de Montpellier I, Montpellier, France, 6Centre for International Health, University of Bergen, Bergen, Norway

University of Pennsylvania, Philadelphia, PA, United States, 7Department of Paediatrics and Child Health, University Teaching Hospital, Lusaka, Zambia, 8INSERM U1058, Montpellier, France, 9Centre Montpellier, Montpellier, France, 10Department of Paediatrics and Child Health, University Teaching Hospital, Lusaka, Zambia, 11Department of Paediatrics and Child Health, University Teaching Hospital, Lusaka, Zambia, 12Centre de Recherche Internationale pour la Santé (CRIS), Bobo-Dioulasso, Burkina Faso, 1Department of Paediatrics and Child Health, Makerere University, Kampala, Uganda, 2School of Public Health, University of Western Cape, Cape Town, South Africa, 3Université de Montpellier I, Montpellier, France, 4Centre for International Health, University of Bergen, Bergen, Norway
Session 0–6 Oral Abstracts
10:00 AM – 12:00 PM Room 312
HIV/SIV Pathogenesis

Moderators
Marcus Altfeld, Ragon Institute of Massachusetts General Hospital, Massachusetts Institute of Technology, and Harvard, Cambridge, MA, United States
R. Keith Reeves, Harvard Medical School, Boston, MA, United States

76 Pyroptosis Drives Both CD4 T Cell Death and Chronic Inflammation in HIV-Infected Lymphoid Tissues
Gilad Doitsch1, Nicole Galloway1, Xin Geng2, Kathryn Monroe1, Zheyuan Yang1, Orlando Zepeda1, Peter Hunt1, Hiroyu Hatano2, Stefanie Sowinski1, Warner C. Greene1
1Gladstone Institute of Virology and Immunology, San Francisco, CA, United States, 2University of California, San Francisco, CA, United States

77 Early ART Initiation Prevents Disruption of the Mucosal Barrier and Subsequent T-Cell Activation
Alexandra Schuetz1, Yuwadee Phuang-ngern1, Rungsun Rerknimitr2, Eugene Kroon3, Nitya Chomche5, Prapan Phanuphak3, Merlin Robb4, Jerome Kim1, Mark de Souza2, Jintanat Ananworanich3, on behalf of the RV254/SEARCH O10 and RCG04 Study Groups
1Retrovirology, USAMC-AFRIMS, Bangkok, Thailand, 2Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, 3SEARCH, Bangkok, Thailand, 4US Military HIV Research Program, Silver Spring, MD, United States

82 Selection for Active SAMHD1 Antagonism in Natural Infections of SIVagm
Chelsea Spragg1,2, Michael Emerman2
1Molecular and Cellular Biology, University of Washington, Seattle, WA, United States, 2Human Biology, Fred Hutchinson Cancer Research Center, Seattle, WA, United States

83 Probiotic and IL-21 Treatment Promotes Th17 Cell Recovery in ARV-Treatment of Pigtail Macaques
Alexandra M. Ortiz1, Zachary A. Klaase1, Kirby M. Carmack1, Carol L. Vinton1, Molly R. Perkins1, Francois Villinger2, Mirko Paldarin3, Jason M. Bronchle1
1LMM, NIH, Bethesda, MD, United States, 2Yerkes National Primate Research Center, Atlanta, GA, United States

Session 0–7 Oral Abstracts
10:00 AM – 12:15 PM Ballroom B/C
Randomized Controlled Trials and Antiretroviral Resistance

Moderators
Urvil M. Parikh, University of Pittsburgh, Pittsburgh, PA, United States
Edmund C. Tramont, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

84LB First-Line RAL + DRV/r Is Non-Inferior To TDF/ FTC + DRV/r: The NEAT001/ANRS143 Randomised Trial
François Raffi1, Abdel G. Babiker2, Laura Richert3, Jean-Michel Molina4, Elizabeth C. George5, Andrea Antinori6, Jose Arribas7, Stefano Vella1, Genevieve Chêne1, Anton L. Pozniak2, NEAT001/ANRS143 Study Group
1University Hospital, Nantes, France, 2MRC Clinical Trials Unit at UCL, London, United Kingdom, 3INSERM U897, Bordeaux, France, 4St Louis Hospital, Paris, France, 5INMI L. Spallanzani, Rome, Italy, 6Hospital La Paz, Madrid, Spain, 7Istituto Superiore di Sanità, Rome, Italy, 8Chelse and Westminster Hospital, London, United Kingdom

85 Efficacy and Tolerability of Atazanavir, Raltegravir, or Darunavir With FTC/Tenofovir: ACTG 5257
Raphael J. Landovitz1, Heather J. Ribaudo2, Ighovherha Ofofokun1, Hongying Wang3, Bryan P. Baugh4, Randi Y. Leavitt5, James F. Rooney6, Daniel Seekins7, Judith S. Currier1, Jeffrey L. Lennox1
1Center for Clinical AIDS Research & Education, University of California Los Angeles, Los Angeles, CA, United States, 2Harvard Center for Biostatistics in AIDS Research, Boston, MA, United States, 3Division of Infectious Diseases, Emory University, Atlanta, GA, United States, 4Janssen Therapeutics, Titusville, NJ, United States, 5Merck & Co, Whitehouse Station, NJ, United States, 6Gilead Sciences, Foster City, CA, United States, 7Bristol-Myers Squibb, Wallingford, CT, United States

86 Attachment Inhibitor Prodrug BMS-663068 in ARV-Exposed Subjects: Week 24 Analysis
Jacob Laizari1, Gulam H. Latif2, Cynthia Brinson3, Juan Echevarria4, Sandra Treviño-Pérez5, Johannes R. Bogner1, David Stock6, Samit R. Joshi7, George J. Hanna1, Max Latallade1, for the A438011 study team
1Quest Clinical Research, San Francisco, CA, United States, 2Maxwell Clinic, Durban, South Africa, 3Central Texas Clinical Research, Austin, TX, United States, 4Hospital Nacional Cayetano Heredia, Lima, Peru, 5Mexico Centre for Clinical Research, Mexico City, Mexico, 6Hospital of the University of Munich, Munich, Germany, 7Bristol-Myers Squibb, Wallingford, CT, United States

87 Sensitive Screening Reveals Widespread Underestimation of Transmitted HIV Drug Resistance
Jin-fen Li, David Kim, Laurie Linley, Richard Kline, Walid Heneine, Jeffrey A. Johnson
Division of HIV/AIDS Prevention, CDC, Atlanta, GA, United States
98 CTX Prophylaxis Discontinuation Among ART-Treated Adults: A Randomized Non-Inferiority Trial
Christina S. Polyak1, Krista Yuhas1, Benson Singsa1, Monica Khambisa1, Judd Watson1, Barbara Richardson2, Grace John-Stewart2
1Military HIV Research Program, Walter Reed Army Institute of Research, University of Washington, Bethesda, MD, United States, 2Global Health, University of Washington, Seattle, WA, United States, 3Kenya Medical Research Institute/ University of Washington, Nairobi, Kenya

Session TD6 Themed Discussion
1:30 PM – 2:30 PM Room 309
Frailty and Functional Impairment
Discussion Leader
Kevin E. Yarasheski, Washington University School of Medicine, St. Louis, MO, United States

766 Geriatric Syndromes Are Common Among Older HIV-Infected Adults
Meredith Greene1,4, Victor Valcour2, Yinghui Miao4, Ken Covinsky1, Joy Madamba1, Monica Mattes1, Harry Lamprini2, Jeffrey Martin2, Steven Deeks2
1Medicine-Geniatrics, University of California San Francisco, San Francisco, CA, United States, 2San Francisco VA Medical Center, San Francisco, CA, United States, 3Northwest Clinic for Research in Aging, Seattle, WA, United States, 4Epidemiology & Biostatistics, University of California San Francisco, San Francisco, CA, United States

99 Reduced In Vivo Replicative Capacity of Drug-Resistant HIV-1 During Acute Infection
Mian-er Cong, Chou-Pong Pau, Waldie Heneine, J. Gerardo Garcia-Lerma
Division of HIV/AIDS Prevention, CDC, Atlanta, GA, United States

90 Oral Sessions

91LB 744 and Rilpivirine as Two-Drug Oral Maintenance Therapy: LAI116482 (LATTE) Week 46 Results
David Margolis1, Cynthia Brinson1, Joseph Enom1, Gary Richmond4, Roger LeBlanc3, Sandy Griffith5, Marty St. Clair1, Marita Williams1, William Spreen1
1GSK, RTP, NC, United States, 2Central Texas Clinical Research, Austin, TX, United States, 3University of North Carolina, Chapel Hill, NC, United States, 4HIV Clinic, Ft. Lauderdale, FL, United States, 5Clinique Opus Inc, Montreal, QC, Canada

92LB Safety and Antiviral Effect of MK-1439, A Novel NNRTI (+FTC/TDF) in ART-Naive HIV-Infected Patients
Javier O. Morales-Ramirez1, Jose M. Gatell2, 3, Margareth Dalcolmo4, Fernanda Mello1, Rafael Duarte5, Carla Loredo5, Valeria Rolla4, Betina Durovni2, 3, Silvia Thompson5, 6
1Clinical Research Puerto Rico, San Juan, Puerto Rico, 2University of Barcelona, Barcelona, Spain, 3Chatham County Health Dept, Savannah, GA, United States, 4AIDS Research Consortium of Atlanta, Atlanta, GA, United States, 5EPIMED/Vivantes Auguste-Viktoria-Klinikum, Berlin, Germany, 6ICH Study Center, Hamburg, Germany, 7Merck, Whitehouse Station, NJ, United States

89 Silent Mutations in HIV-1 Subtype B Reverse Transcriptase Selected by ART Restore Viral Fitness
Sushama Telwate1, 2, Anna C. Hearps1, 3, Adam Johnson1, Con Sonza1, Nicolaos P. Suis-Cremer1, Richard P. Harrigan1, Gilda Tachdjian1, 3
1Centre for Biomedical Research, Burnet Institute, Melbourne, Australia, 2Department of Microbiology, Monash University, Melbourne, Australia, 3Department of Microbiology and Immunology, University of Melbourne, Melbourne, Australia

94 Tuberculosis Infection in Early Childhood in Uganda and the Influence of HIV Exposure

1University of California, San Francisco, San Francisco, CA, United States, 2Makerere University College of Health Sciences, Kampala, Uganda, 3Infectious Diseases Research Collaboration, Kampala, Uganda

95 Effect of Xpert MTB/RIF On Early Mortality in Adults With Suspected TB: A Pragmatic Randomized Trial
Gavin Churchyard1, Keggan McCarthy1, Katherine L. Fielding1, Wendy Stevens1, Violet Chihota1, Mark Nicoll1, Norbert Ndjeka1, Alison D. Grant1, Gavin J. Churchyard1
1London School of Hygiene & Tropical Medicine, London, United Kingdom, 2Aurum Institute, Johannesburg, South Africa, 3University of Cape Town, Cape Town, South Africa, 4South African Department of Health, Pretoria, South Africa

96LB Xpert as the First-Line TB Test in South Africa: Yield, Initial Loss To Follow-Up, Proportion Treated
Katherine L. Fielding, Keggan McCarthy, Helen Cox1, Linda Erasmus1, Siluwe Giniindzi2, Anna Vassali3, Lindwe Mvusi3, Chris Dye1, Alison D. Grant1, Gavin J. Churchyard1
1London School of Hygiene & Tropical Medicine, London, United Kingdom, 2Aurum Institute, Johannesburg, South Africa, 3University of Cape Town, Cape Town, South Africa, 4National Health Laboratory Service, Johannesburg, South Africa, 5South African Department of Health, Pretoria, South Africa, 6World Health Organization, Geneva, Switzerland

Session 0-8 Oral Abstracts
10:00 AM – 12:00 PM Ballroom A
TB and Other Coinfections

Moderators
Anne F. Luetkemeyer, University of California San Francisco, San Francisco, CA, United States
Alison D. Grant, London School of Hygiene and Tropical Medicine, London, United Kingdom

93 A Phase 2 Trial of a Rifapentine Plus Moxifloxacin-Based Regimen for Pulmonary TB Treatment
Marcus B. Conde1, Solange C. Cavalcante2, 3, Margareth Dalcolmo1, Fernanda Mello1, Rafael Duarte5, Carla Loredo5, Valeria Rolla4, Betina Durovni2, 3, Silvia Cohrl1, Richard E. Chaissoun1, Susan E. Dorman1
1Thoracic Diseases Institute, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil, 2Municipal Health Secretariat, Rio de Janeiro, Brazil, 3Instituto de Pesquisa Clínica Evandro Chagas, Rio de Janeiro, Brazil, 4Center de Referencia Professor Hello Fraga, ENG-Fiocruz, Rio de Janeiro, Brazil, 5Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

88 Transmitted HIV-1 Drug Resistance Between Partner-Pairs
Joanne Stekler1, Rachel Payant2, Ingrid Beck3, Brandon Maust1, Sarah Holt1, 2, Janine Maenza3, Claire E. Stevens4, James I. Mullins5, Ann C. Collier1, Lisa M. Frenkel1, 2
1University of Washington, Seattle, WA, United States, 2Seattle Children’s Hospital, Seattle, WA, United States, 3Fred Hutchinson Cancer Research Center, Seattle, WA, United States
676 Physical Function Impairment On Quality of Life Among Persons Aging With HIV Infection
Kristine M. Erlandson, Amanda A. Althouse, Catherine M. Jankowskii, Samantha MaWhinney, Wendy M. Kohrt, Thomas B. Campbell
University of Colorado Anschutz Medical Campus, Aurora, CO, United States

676 Cell-Mediated CMV Responses in HIV-Infected Persons With Impaired Physical Function
Kristine M. Erlandson, Amanda A. Althouse, Rick Rapaport, Brent E. Palmer, Cara C. Wilson, Samantha MaWhinney, Thomas B. Campbell
University of Colorado Anschutz Medical Campus, Aurora, CO, United States

676 Frailty, Inflammation and Mortality Among Aging HIV-Infected and At-Risk Injection Drug Users
Damani A. Figuett, Ravi Varadhan, Shruti H. Mehta, Todd T. Brown, Sean X. Leng, Gregory D. Kirk
The Johns Hopkins University, Baltimore, MD, United States

673 Brisk Walking Improves Inflammatory Markers in cART-Treated Patients
Valeria Longo1, Matteo Bonati2, Simona Bossolasco1, Laura Galli3, Andrea Caumo3, Gaspare Pave3, Adriano Lazzarin1, Giampiero Merati2, Antonio La Torre4, Paola Cinqueto1
1Infectious Diseases, San Raffaele Scientific Institute, Milano, Italy, 2Biomedical Sciences for Health, Université degli Studi di Milano, Milano, Italy, 3Pathophysiology and Transplantation Department, Università degli Studi di Milano, Milano, Italy

Session TD8 Themed Discussion
1:30 PM – 2:30 PM Room 304
Clinical Pharmacology in Patient Care
Discussion Leader
Stephen Taylor, Birmingham Heartlands Hospital, Birmingham, United Kingdom

496 Pharmacokinetics of Raltegravir 400 vs 800 mg BID With Intermittent Rifampicin Dosed Thrice Weekly
Helen E. Reynolds1, Deirdre Egan1, Laura Else1, Mas Chaponda2, Ales Chrdle1, David J. Back1, Saye H. Khoi1
1University of Liverpool, Liverpool, United Kingdom, 2Royal Liverpool University Hospital, Liverpool, United Kingdom

497 Pharmacokinetics of Faldaprevir and Antiretrovirals in Patients With HIV/HCV Coinfection
Jürgen K. Rockstroh1, Marc-Antoine Valantin2, Josep Mallol3, Massimo Puddu4, Juan Antonio Pineda1, Patrick Inglis2, Marina Núñez1, Fenglei Huang4, Richard Vinislo1, Douglas Dieterich7
1Department of Medicine I, University of Bonn, Bonn, Germany, 2Josep Puigvert Foundation, Barcelona, Spain, 3Service des Maladies Infectieuses des Tropicales, Hôpital Pitié-Salpêtrière, Paris, France, 4Hospital Clinic-University of Barcelona, Barcelona, Spain, 5Department of Infectious Diseases, AO Ospedale Niguarda Ca’ Granda Milano, Milan, Italy, 6Unit of Infectious Diseases and Microbiology, Hospital Universitario de Valme, Seville, Spain, 7Medical Center for Infectious Diseases, Berlin, Germany, 8Wake Forest University Health Sciences, Winston-Salem, NC, United States, 9Boehringer Ingelheim Pharmaceutical, Inc, Ridgefield, CT, United States, 10Mount Sinai Medical Center, New York, NY, United States

504 Relative Genetic Contribution To the Pharmacokinetics of Commonly Prescribed Antiretrovirals
Marco S. Siccardi1, Adeniyi Olagunju2, 3, Marco Simiele1, Antonio D’Avolio1, Andrea Calcagno1, Giovanni Di Perri1, Stefano Bonona2, Andrew Owen3

1Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, GA, United States, 2ICF International and University of California San Diego, San Diego, CA, United States, 3ICF International, Atlanta, GA, United States

Ongoing HIV-1 Subtype B Transmission Networks in the Netherlands
205 Using HIV Network Data to Inform Real Time Prevention Interventions
Susanne May1, Sanjay R. Mehta1, Christy M. Anderson2, Jason A. Young3, Joel G. Wertheim2, Sanjay R. Mehta1, Susanne May2, Davey M. Smith1
1Medicine, University of California San Diego, San Diego, CA, United States, 2Biostatistics, University of Washington School of Public Health, Seattle, WA, United States

207 Transmission Networks of HIV-1 Subtype B, CRF01_AE and CRF51_01B Among MSM in Singapore
Kim Tien Ng1, Kah Ying Ng2, Wei Xin Khong1, Oliver Laeyendecker1, 2, Thomas C Quinns3, 4, Adeeba Kamarulzaman1, Don Teo Ng1, kok Keng Tee1
1Centre of Excellence for Research in AIDS (CERiA), Department of Medicine, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia, 2Institute of Infectious Disease and Epidemiology, Communicable Disease Centre, Tan Tock Seng Hospital, Novena, Singapore, 3Division of Infectious Diseases, The John Hopkins School of Medicine, Baltimore, MD, United States, 4Laboratory of Immunoregulation, Division of Intramural Research, National Institute of Allergy and Infectious Disease, National Institutes of Health, Bethesda, MD, United States
Session TD9 Themed Discussion
1:30 PM – 2:30 PM Room 312
Gut and Immune Activation

Discussion Leader
Peter W. Hunt, University of California San Francisco, San Francisco, CA, United States

312 Rapid Gut-Homing of Plasmacytoid Dendritic Cells During Acute SIV Infection
Hailey Li, Jacqueline Gillis, R. Keith Reeves
NEPRC, Harvard Medical School, Southborough, MA, United States

313 CCR6+ and CD161+ CD4 T Cell Loss Contributes To the Pathogenesis of SIV Infection in Rhesus Macaques
Colleen S. McGarry1, Luca Micci1, Emily S. Ryan1, Maria J. Buzori2, Amy Shaw2, Mathias Lichterfeld4, Guido Silvestri1,2,3,4, Attab A. Ansari3, Mirko Paiardini5,6,7,8,9,10
1Department of Microbiology and Immunology, Emory University, Atlanta, GA, United States, 2Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States, 3Department of Pathology and Laboratory Medicine, Emory University, Atlanta, GA, United States, 4Department of Chemical and Bioengineering, Swiss Federal Institute of Technology, Zürich, Switzerland, 5University of Life Sciences, Aas, Norway, 6Infectious Diseases, Oslo University Hospital, Oslo, Norway, 7Department of Microbiology and Immunology, Emory University, Atlanta, GA, United States, 8Department of Medical Microbiology and Immunology, University of CA, Davis, CA, United States, 9Division of Vaccine and Infectious Disease Sciences, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, 10Department of Global Health, University of Washington, Seattle, WA, United States

315 Decreased Diversity of Gut Microbiota Is Associated With Immune Status During HIV-1 Infection
Piotr Nowak1, Babilonia Barqasho2, Ekatarina Avershina2, Kajsa Noyan1, Jan Vesterbacka1, Marius Trosseid4, Knut Rudi3, Anders Söderberg1
1Department of Infectious Diseases, Karolinska Institute, Huddinge, Sweden, 2Department of Laboratory Medicine, Karolinska Institute, Huddinge, Sweden, 3Department of Chemistry, Biotechnology and Food Science, Norwegian University of Life Sciences, Aas, Norway, 4Department of Chemistry, Biotechnology and Food Science, Norwegian University of Life Sciences, Aas, Norway

317 Dysbiotic Bacteria Translocate in Progressive SIV Infection
Zachary Klaese5, Alexa Schwartzman5, Alexandra Ortiz5, Lauren Canary5, Mariam Quinones5, Jason Brenchley1
1Laboratory of Molecular Microbiology, NIAID/NH, Bethesda, MD, United States, 2NIAD/NH, Bethesda, MD, United States

318 Breaches in Colonic Claudin-4 Expression Correlate With T-Cell Activation in HIV-1 Infection
Louise Greamhead5, Anna Mroz2, Hiromi Kudo1, Brian Gazzard1, Mark Nelson1, Robert D. Gallow1, Alan Steel1, Peter Kelleher1
1Imperial College, London, United Kingdom, 2Chelsea and Westminster Hospital NHS Trust, London, United Kingdom

319 Increased Immune Activation After Gut Permeabilization in SIV-Infected African Green Monkeys
Jan Kristoff1, Thaïdra Gaulin1, Rajeev Gautam2, Dongzhu Ma3, Jacob Estes1, Russell Tracy2, Christian Apetrei1, Steve Nelson1, Gregory Bagby1, Ivone Pandrea1
1Center for Vaccine Research, University of Pittsburgh, Pittsburgh, PA, United States, 2UCRC, Los Angeles, CA, United States, 3Center for Vaccine Research, NIAID/NH, Bethesda, MD, United States, 4NCH/NH, Frederick, MD, United States, 5University of Vermont, Colchester, VT, United States, 6Louisiana State University, New Orleans, LA, United States

Session TD10 Themed Discussion
1:30 PM – 2:30 PM Room 311
Reproductive Hormones in Women: Impact On Risk and Barrier Dysfunction

Discussion Leader
Susan Cu-Uvin, Brown University, Providence, RI, United States

844 Depot-Medroxyprogesterone Acetate Does Not Increase Genital HIV SHIV Shedding in Macaques
Jessica Radzio1,2, Kristizina Hanley3, Debra Hanson1, James Mitchell1, Leecresia Jenkins1, Sharon Ellis1, Frank Dyenuks1, Walid Heneine1, J. Gerardo Garcia-Lerma1
1Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, GA, United States, 2Pathology, Emory University, Atlanta, GA, United States

846 Hormonal Contraceptives Increase Innate Immune Effector Molecules in Cervicovaginal Secretions
Brandon L. Guthrie1, Robert Y. Choi2, Alison C. Roxby3, Rose Bosire1, Barbara Lohman-Payne1,2, Taha Hirbod2, Carey Farquhar3,2, Kristina Bridler1
1Department of Global Health, University of Washington, Seattle, WA, United States, 2Department of Medicine, University of Washington, Seattle, WA, United States, 3Center for Public Health Research, Kenya Medical Research Institute, Nairobi, Kenya, 4Department of Medicine Salina, Karolinska Institutet, Stockholm, Sweden

847 Injectable Contraception and HIV Acquisition in the VOICE Study (MTN-003)
Lisa M. Noguchi1,2, Barbra Richardson1, Z. Mike Chirenje1, Gita Ramjee1,2, Donnacha Considine1,2,3,4,5,6,7,8,9,10,11,12
1Laboratory of Molecular Microbiology, NIAID/NH, Bethesda, MD, United States, 2Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, GA, United States, 3Department of Laboratory Medicine, Karolinska Institute, Huddinge, Sweden, 4Department of Microbiology, Biotechnology and Food Science, Norwegian University of Life Sciences, Aas, Norway, 5Division of Infectious Diseases, Karolinska Institute, Huddinge, Sweden, 6Department of Chemistry, Biotechnology and Food Science, Norwegian University of Life Sciences, Aas, Norway, 7Interface Science, University of Oslo, Oslo, Norway, 8Institut de Génomique Humaine, Université de Lausanne, Lausanne, Switzerland, 9Inscriptions, Villejuif, France, 10INSERM, Villejuif, France, 11Inserm, Villejuif, France, 12Institut de Génomique Humaine, Université de Lausanne, Lausanne, Switzerland, 13Infections, Oslo University Hospital, Oslo, Norway

845 Dysregulation of Estradiol Signaling Contributesto Mucosal Barrier Dysfunction HIV+ Women
Sumathi Sankaran-Walters1, Anne Fenton1, Chris Gaulke1, Lauren Nagy3, Irina Grishina2, Jason Flam2, Thomas Prindiville3, Satya Dandekar1
1Medical Microbiology and Immunology, University of CA, Davis, CA, United States, 2Internal Medicine, University of CA, Davis, CA, United States, 3Center for Public Health Research, Kenya Medical Research Institute, Nairobi, Kenya, 4Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden

Session TD16 Themed Discussion
1:30 PM – 2:30 PM Ballroom B/C
Real-World Experiences With Hepatitis C

Discussion Leader
Marion G. Peters, University of California San Francisco, San Francisco, CA, United States

668 Telaprevir in Treatment-Experienced HIV-HCV G1 Coinfected Patients (ANRS HC26 TelapreVH)
Laurent Cottereau4, Corinne Vincent1, Philippe Sogni2, Isabelle Fournier3, Hugues Aumaitre1, Pierre De Truchis4, Isabelle Rosa3, Stéphane Chevalier3, Jean-Pierre Aboukler2, Jean-Michel Molina1,11
Oral Sessions

660 Boceprevir/Telaprevir-Based Therapy in HIV-Infection: Interim Analysis of a Multicenter Cohort
Karim Neukam1,2, Daniela Munteanu3,4, Antonio Rivero3, Annette Haberl5, Manuel Marquez6, Patrick Inglis7, Ignacio de los Santos-Gil8, Thomas Lutz9, Juergen K. Rockstroh2, Juan A. Pineda1
1Unit of Infectious Diseases and Microbiology, Hospital Universitario de Valme, Seville, Spain, 2University of Liverpool, Liverpool, United Kingdom, 3Bonn University Hospital, Bonn, Germany, 4Matei Bals National Institute of Infectious Diseases, Bucharest, Romania, 5Hospital Universitario Reina Sofia, Cordoba, Spain, 6Frankfurt University Hospital, Frankfurt am Main, Germany, 7Hospital Virgen de la Victoria, Malaga, Spain, 8Medical Center for Infectious Diseases, Berlin, Germany, 9Hospital Universitario de la Princesa, Madrid, Spain, 10Infectiologikum, Frankfurt am Main, Germany

658 Protease Inhibitors To Treat Hepatitis C in the Swiss HIV Cohort Study: High Efficacy But Low Uptake
Sebastian Haubitz1, Verena Schaarer1, Juan Ambrosioni2, Matthias Cavassini4, Marcel Stoeckle4, Patrick Schmidt4, Laurent Decosterd1, Karin Metzner2, Jan Fehr2, Andri Rauch1
1Division of Infectious Diseases, Bern, Switzerland, 2Division of Infectious Diseases, Zurich, Switzerland, 3Division of Infectious Diseases, Geneva, Switzerland, 4Division of Infectious Diseases, Lausanne, Switzerland, 5Division of Infectious Diseases, Basel, Switzerland, 6Division of Infectious Diseases, St Gallen, Switzerland

655 Slow HCV-RNA Decay and Early Resistance Predict the Risk of Failure To TVR/BOC Treatment
Francesca Ceccherini-Silberstein1, Valeria Conto1, Velia Chiara Di Maio1, Daniele Di Paolo1, Sergio Babudieri1, Antonio Di Biagio1, Massimo Andreoni1, Giustino Parruti1, Giuliano Rizzardi1, Carlo Federico Perno1
1Department of Experimental Medicine and Surgery, University of Rome Tor Vergata, Rome, Italy, 2Hepatology Unit, University Hospital of Rome Tor Vergata, Rome, Italy, 3Infectious Diseases Unit, Department of Clinical and Experimental Medicine, University of Sassari, Sassari, Italy, 4S. Martino Hospital, Genoa, Italy, 5Infectious Diseases Unit, University Hospital of Rome Tor Vergata, Rome, Italy, 6Infectious Diseases Unit, Pescara General Hospital, Pescara, Italy, 7Division of Infectious Diseases, Hospital Sacco of Milan, Milan, Italy

661 Favorable Adverse Event Profile of Sofosbuvir/Ribavirin Versus Standard of Care for Hepatitis C
Kerry Townsend1, Shivakumar Narayanan2, Amy Nelson1, Adrian Majid3, Luciano Kapelusznik4, Patrick英格利5, Laurent Decosterd1, Karin Metzner2, Jan Fehr2
1LIR, NIAID, NIH, Bethesda, MD, United States, 2Institute of Human Virology, Baltimore, MD, United States

641 Sustained Virologic Response and the Risk of Liver Decompensation in HCV and HIV/HCV Patients
Temitope O. Olufade1, Li Wang1, Scott Devine1, Onur Basar2, Vincent Lo Re3
1US Outcomes Research, Merck Sharpe & Dohme, North Wales, PA, United States, 2STATinMED Research, Dallas, TX, United States, 3Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, United States

650 Predicting Risk of ESDL in HIV/HCV Patients for Individualized HCV Therapy Decisions
Vincent Lo Re1, Janet P. Tate2, Adriel A. Butt3, Marina B. Klein4, Cynthia Gilbert1, David Rimland5, Matthew B. Goetz6, Jay N. Kostman1, Amy C. Justice2, Russell Localio1
1University of Pennsylvania, Philadelphia, PA, United States, 2VA Connecticut Healthcare System, West Haven, CT, United States, 3University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, 4McGill University Health Centre, Montreal, QC, Canada, 5Washington DC VA Medical Center, Washington, DC, United States, 6Atlanta VA Medical Center, Atlanta, GA, United States, 7VA Greater Los Angeles Healthcare System, Los Angeles, CA, United States

POSTER SESSIONS

2:30 PM–4:00 PM
(Use the Post Abstract section of the Program at a Glance, page 37 to 106, for specific posters in each session)

Session P-A4 Late Events in HIV Replication
Session P-A5 Atezavir, Atezavir, Atezavir
Session P-B2 Application of NGS To Viral Profiling
Session P-C6 Clades and Pathogenesis
Session P-C7 Correlative Marker Studies
Session P-C8 Elite Controllers
Session P-C9 Pathogenesis: Insights From Clinical Trials
Session P-C10 Innate Immunity and Pathogenesis
Session P-D2 New SIV Models
Session P-D3 SCID Mice
Session P-D4 Non-Pathogenic vs Pathogenic Hosts
Session P-E3 New Technologies in Immunology
Session P-E4 Monocytes, Dendritic Cells, NK Cells
Session P-E5 Pre-Clinical Vaccine Studies
Session P-F4 Methods for Measuring Reservoirs
Session P-F5 What and Where Is the Reservoir?
Session P-F6 What Can We Learn From Bone Marrow Transplantation?
Session P-G3 Neuropathogenesis
Session P-G4 Host Genetics in HAND
Session P-G5 PML and Other CNS Infections
Session P-G6 CNS Viral Genetics
Session P-H2 ART Initiation, Monitoring, and Outcomes
Session P-I3 Mechanisms of HIV Drug Resistance
Session P-L4 HIV Drug Resistance Variants
Session P-M2 HIV Diagnostics
Session P-N3 HCV: Prognosis and Impact of Treatment, Including Liver Transplantation
Session P-N4 HCV Treatment: Real-World Experience
Session P-N5 HCV: The Cascade
Session P-P4 Risk Factors and Incidence: MI and Stroke
Session P-P5 Bone Disease and HIV
Session P-P6 Lung Disease and HIV
Session P-Q5 Hepatic Fibrosis and Other Hepatic Complications
Session P-Q6 Epidemiology and Transmission of TB
Session P-Q7 TB Screening and Diagnosis
Session P-R3 Latent TB Screening and Treatment
Session P-R4 Inflammatory and Immune Activation Markers in TB
Session P-R5 Impact of ART on TB Risk and Disease
Session P-R6 Pregnancy Incidence and Outcomes Among Women in ART Programs
Session P-T3 Cellular and Immune Correlates of MTCT
Session P-T4 Characteristics of Pregnant Women in PMTCT
Session P-T5 Early Infant HIV Diagnosis
Session P-U4 Host and Immune Response in Children and Adolescents
99 HIV and Elevated Cancer-Specific Mortality Following Cancer Diagnosis in the United States

Anna E. Coughlin, Meredith S. Shieh, Eric A. Engels
Division of Cancer Epidemiology and Genetics, National Cancer Institute, Washington, DC, United States

100 Impact of Kaposi Sarcoma On Survival in HIV-Infected African Adults On Antiretroviral Therapy

Stephen B. Aslimwe1,2, Miriam Laker-Oketa1, John Bennett1, Adrienne Mocotile1, David Glidden1, Jessica Haberer4, Mwebesa Bwana1, Peter Hunt1, David Bangsberg1, Edward Mbidde1, Jeffrey Martin2
1Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA, United States, 2Department of Internal Medicine, Mbarara Regional Referral Hospital, Mbarara, Uganda, 3Infectious Diseases Institute, Kampala, Uganda, 4Department of Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, MA, United States

101 Prospective Characterization of Kaposi Sarcoma Herpesvirus Inflammatory Cytokine Syndrome

Mark N. Polizzotto1, Thomas S. Ulrick1, Kathleen M. Wywiler1, Karen Aleman1, Vickie Marshall1, Denise Whitby1, Stefania Pittaluga1, Seth Steinberg1, Irini Sereti1, Robert Yarchoan1
1HIV and AIDS Malignancy Branch, National Cancer Institute, Bethesda, MD, United States, 2Viral Oncology Section, Frederick National Laboratory for Cancer Research, Frederick, MD, United States, 3Laboratory of Pathology, National Cancer Institute, Bethesda, MD, United States, 4Biositistics and Data Management Section, National Cancer Institute, Bethesda, MD, United States, 5HIV Pathogenesis Unit, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

102 Quadrivalent HPV Vaccine Demonstrates Immune Memory in HIV-1-Infected Men

Timothy Wilkin1, Shelly Lonsing1, Mark Einstein1, Jeannette Lee1, Stephen Goldstone2, Elizabeth A. Stier1, Michael Berry1, Naomi Jay1, Ronald Mitsuyasu2, Joel Palefsky3
1Division of Infectious Diseases, Weill Cornell Medical College, New York, NY, United States, 2Department of Biostatistics, University of Arkansas for Medical Sciences, Little Rock, AR, United States, 3Department of Obstetrics & Gynecology and Women's Health, Albert Einstein College of Medicine and Montefiore Medical Center, New York, NY, United States, 4University of Arkansas for Medical Sciences, Little Rock, AR, United States, 5Cahn School of Medicine at Mount Sinai, New York, NY, United States, 6Division of Obstetrics and Gynecology, Boston University Medical Center, Boston, MA, United States, 7Department of Medicine, University of California San Francisco, San Francisco, CA, United States, 8University of California San Francisco, San Francisco, CA, United States, 9UCLA CARE Center, University of California Los Angeles, Los Angeles, CA, United States

103 HIV-1 Infection Alters Intestinal Expression of Antiretroviral Drug Transporters and Enzymes

Olena Kis6, MD, Tozamnel Hoque1, Sharon L. Walmsley1, Sumathi Sankaran-Walters5, Satya Danekar2, Reina Bendaian2
1Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada, 2University of Toronto, Toronto, ON, Canada, 3Division of Infectious Diseases, University Health Network, Toronto, ON, Canada, 4Medical Microbiology and Immunology, University of California, Davis, CA, United States, 5Medical Microbiology and Immunology, University of California, Davis, CA, United States

104 Tenofovir-Emtricitabine Directly Observed Dosing: 100% Adherence Concentrations (HPTN 066)

Craig W. Hendrix1, Adriana Andrade2, Angela D. Kashuba1, Mark Marzinke2, Peter L. Anderson1, Ayana Moore1, Vanessa Elharrar1, Lei Wang1, Kenneth H. Mayer1, Kristine B. Patterson2
1The Johns Hopkins University, Baltimore, MD, United States, 2University of North Carolina (Chapel Hill), Chapel Hill, NC, United States, 3University of Colorado, Aurora, CO, United States, 4FHI 360, Durham, NC, United States, 5National Institutes of Health, Rockville, MD, United States, 6SCHARP, Seattle, WA, United States, 7Fenway Health, Boston, MA, United States

105 Efavirenz Pharmacokinetics in HIV+ Persons Receiving Rifapentine and Isoniazid for TB Prevention

Anthony T. Podany1, Yajing Bao2, Richard E. Chaisson3, Susan Swindells4, Janet W. Andersen1, Thando Mwelase3, Khuanlchai Supparatpinyo5, Amita Gupta6, Constance A. Benson7, Courtney V. Fletcher2
1College of Pharmacy, University of Nebraska Medical Center, Omaha, NE, United States, 2Statistical & Data Analysis Center, Harvand School of Public Health, Boston, MA, United States, 3Division of Infectious Diseases, The Johns Hopkins University, Baltimore, MD, United States, 4Infectious Diseases/Internal Medicine, University of Nebraska Medical Center, Omaha, NE, United States, 5Clinical HIV Research Unit, Wits Health Consortium, Johannesburg, South Africa, 6Chiang Mai University, Chiang Mai, Thailand, 7Antiviral Research Center, University of California San Diego, San Diego, CA, United States

106 Pharmacokinetic Variability in TB Therapy: Associations With HIV and Effect On Outcome

Derek J. Sloan1, Alessandro Schipani2, David Waterhouse3, Lisa Stone1, Henry C. Mwandumba1, Anthony E. Butterworth1, Robert S. Heyderman1, Elizabeth L. Corbett1, Saye H. Khoo1, Geraint R. Davies1
1Malawi Liverpool Wellcome Trust Clinical Research Programme, Blantyre, Malawi, 2University of Liverpool, Liverpool, United Kingdom, 3Liverpool School of Tropical Medicine, Liverpool, United Kingdom, 4College of Medicine, University of Malawi, Blantyre, Malawi

Session 54 Symposium
4:00 PM – 6:00 PM Ballroom B/C

TB: Looking To the Future: Resistance, Persistence, Monitoring, and Control

Target audience: This session is directed to clinicians and scientists interested in the pathogenesis, diagnosis, treatment, and prevention of TB.

Level of knowledge: It is assumed that learners are familiar with basic aspects of the disease, drug therapies, and development of resistance and with current tools available for disease monitoring on an individual and population basis.

Objectives: At the completion of the session, learners will be able to describe:
• Methods for sequencing MDR and XDR TB strains and factors beyond inadequate adherence that contribute to emergence of resistance
• The pathogenesis of latency, novel animal models of latency, and implications for treating latent TB infections
• Use of PET-CT, PET-MRI, and other novel imaging to detect mycobacterial replication, tissue inflammation, and responses to TB therapy
• Insights gained from population-based studies of TB prevention
Conveners
Neil A. Martinson, University of the Witwatersrand, Johannesburg, South Africa
Jean William Pape, Weill Cornell Medical College, New York, NY, United States, and Centres GESKIO, Port-au-Prince, Haiti

107 The Genetics and Pathogenesis of MDR and XDR TB Drug Resistance
Megan B. Murray
Harvard Medical School, Boston, MA, United States

108 Is Latent TB Infection Really Latent?
Petros C. Karakousis
The Johns Hopkins University School of Medicine, Baltimore, MD, United States

109 Quantifying TB Treatment Response Using PET/CT
Clifton E. Barry III
National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

110 Population-Level Control of HIV-Related TB
Peter Godfrey-Faussett
Joint United Nations Programme on HIV/AIDS (UNAIDS), Geneva, Switzerland

Session S5 Symposium
4:00 PM – 6:00 PM  Ballroom A
Visualizing the Virus

Target audience: This session is directed to scientists and clinicians who are interested in current concepts of how the HIV viral particle is assembled and how it interacts with cellular proteins, particularly during entry. Learners will also learn about state-of-the-art technological approaches and breakthroughs that have enabled visualization and analysis of HIV virions and proteins in real time.

Level of knowledge: It is assumed that learners will have a basic understanding of the HIV virion components and virus life cycle.

Objectives: At the completion of the session, learners will be able to:
• Appreciate technological advances that are being applied to study HIV particles, viral proteins, and protein-protein interactions involved in viral entry
• Describe current views of how the HIV virion is assembled and how key cellular interactions contribute to infection and virus production
• Describe recent advances in structural biology that have enabled complex viral proteins to be visualized

Conveners
Hans-Georg Kräusslich, University of Heidelberg, Heidelberg, Germany
Eric O. Freed, National Cancer Institute, Frederick, MD, United States

111 An Ingenious Cloak for Subterfuge: The HIV Capsid Structure
Angela M. Gronenborn
University of Pittsburgh, Pittsburgh, PA, United States

112 Structure of a Soluble, Cleaved HIV-1 Env Trimer and Its Interaction With Broadly Neutralizing Antibodies
Ian A. Wilson
The Scripps Research Institute, La Jolla, CA, United States

113 Imaging the Molecular Dance of Single HIV-1 Env Molecules
Walter H. Mothes
Yale University, New Haven, CT, United States

114 Kill HIV by Starvation: SAMHD1 as a Potent Viral Restriction Factor and a Master Regulator of Cellular dNTP Metabolism
Yong Xiong
Yale University, New Haven, CT, United States

Session S6 Symposium
4:00 PM – 6:00 PM  Room 304
Know Your Epidemic: From Data To Action

This session aims to inform the attendees of the value of data in furthering the understanding of the epidemiology of the HIV epidemic and the critical role that data and evidence can play in informing research as well as policy decisions regarding HIV. The availability of various population-level surveys and the wealth of other research findings allow for a more effective response to the HIV epidemic.

Target audience: This session is directed to clinicians, researchers and policy makers who are interested in use of data and evidence to inform their work

Level of knowledge: It is assumed that learners are familiar with the global HIV epidemic, basic epidemiology of HIV, and affected populations

Objectives: At the completion of the session, learners will be able to:
• Describe the complexity of the global epidemiology of HIV
• List available population surveys related to HIV
• Recognize the evolution of the HIV epidemic within subpopulations
• Identify ways in which data and evidence can be used to inform policy

Conveners
John Stover, Futures Institute, Glastonbury, CT, United States
Beatriz Grinsztejn, Instituto de Pesquisa Clinica Evandro Chagas-Fiocruz, Rio de Janeiro, Brazil

115 Population Surveys: What Do They Show?
Peter D. Ghys
Joint United Nations Programme on HIV/AIDS (UNAIDS), Geneva, Switzerland

116 MSM in the UK: Prevention Effects of ART in Perspective
Andrew Phillips
University College London, London, United Kingdom

117 Understanding Networks of HIV Transmission
Stéphane Helleringer
Columbia University, New York City, NY, United States

118 From Evidence To Policy: Experience From Swaziland
Velephi J. Okello
Swaziland National AIDS Programme, Mbabane, Swaziland
Oral Sessions

THURSDAY MARCH 6, 2014

Session PL5 Plenary
8:30 AM – 9:00 AM Auditorium

119 HIV-1 Infection and Type-1 Interferon
Michael H. Malin
King’s College London, London, United Kingdom

Session PL6 Plenary
9:00 AM – 9:30 AM Auditorium

120 PEPFAR/Global Fund at 10 years: Past, Present, and Future
Stefano M. Bertozzi
University of California Berkeley School of Public Health, Berkeley, CA, United States

Session 0-9 Oral Abstracts
10:00 AM – 12:15 PM Room 312

Interferon and Antibody at the Interface of Innate and Adaptive Immunity To HIV

121 Cryo-EM Structures of the HIV-1 Env Trimer Reveal the Full Extent of Neutralizing Antibody Epitopes
Andrew B. Ward1, Dmitry Lyumkis2, Natalia de Vlai3, Jean-Philippe Julien4, Albert Cupo5, Per Johan Klase6, Rogier Sanders7, John Moore8, Ian Wilson9
1Integrative Structural and Computational Biology, The Scripps Research Institute, La Jolla, CA, United States, 2Weill Cornell Medical College, New York, NY, United States, 3Academic Medical Center, Amsterdam, Netherlands

122LB Immunogenicity of Cleaved, Soluble BG505 SOSIP.664 Native-Like Trimers in Rabbits
John P. Moore
Microbiology/Immunology, Weill Medical College, New York, NY, United States

123 Identification of a New Neutralization Target at the N262/N448 Glycosylation Sites On HIV-1 gp120
Xueling Wu1, Tongqiu Zhou1, Ivelin S. Georgiev2, Sijy O’Dell2, Mark Louder2, Dennis R. Burton3, Wayne C. Koff4, Martin Markowitz5, John P. Moore6, Gideon Schreiber7, Daniel C. Douek8
1Aaron Diamond AIDS Research Center, New York, NY, United States, 2Vaccine Research Center, Bethesda, MD, United States, 3International AIDS Vaccine Initiative, New York, NY, United States

124 CD169 Mediates HIV-1 Evasion From Detection by α-gp120 Neutralizing Antibodies in Dendritic Cells
Hisashi Akiyama1, Nora G. P. Ramirez2, Manasa Gudheti2, Suryaram Gummuluru3
1Microbiology, Boston University School of Medicine, Boston, MA, United States, 2, 3Vutara Inc., Salt Lake City, UT, United States

125 Tetherin Antagonism by Vpu Protects HIV-Infected Cells From ADCC
Juan F. Arias1, Lisa N. Heyer2, Benjamin von Bredow2, Kim L. Weisgrau2, Brian Moldt3, Dennis R. Burton3, Eva G. Rakasz4, David T. Evans5
1Department of Pathology and Laboratory Medicine, University of Wisconsin, Madison, WI, United States, 2Department of Microbiology and Immunobiology, Harvard Medical School, Southborough, MA, United States, 3Wisconsin National Primate Research Center, University of Wisconsin, Madison, WI, United States, 4Department of Immunology and Microbial Science, The Scripps Research Institute, La Jolla, CA, United States

126 HIV Nef and Vpu Protect HIV-infected CD4+ T Cells From ADCC Through Downmodulation of CD4 and BST2
Tram N. Q. Pham1, Sabelo Lukhele1, Fadi Hajar2, Jonathan Richard2, Rajesh M. Valanparadil, Halima Medjahed1, Mathieu Coutou3, Andres Finzi4, Eric A. Coen4,5
1Institut de Recherches Cliniques de Montréal, Montreal, QC, Canada, 2Department of Medicine, McGill University, Montreal, QC, Canada, 3Centre de Recherche du Centre Hospitalier de l’Université de Montréal, Montreal, QC, Canada, 4Department of Microbiology, Infectology and Immunology, Université de Montréal, Montreal, QC, Canada

127 Identification of HIV-infected CD4+ T Cells Using HIV RNA and Broadly Neutralizing Antibodies
Joseph P. Casazza1, Alexander C. Vostal1, Irene R. Primmer1, David R. Ambrozak1, Amarendra Pegu2, Eli Botz2, Mark K. Louder3, Daniel C. Douek4, John R. Mascola5, Richard A. Koup6
1Immunology Laboratory, NIAID, Bethesda, MD, United States, 2Virology Laboratory, NIAID, Bethesda, MD, United States, 3Human Immunology Section, NIAID, Bethesda, MD, United States

128 Type I Interferon Signaling is Critical for Early Control of Immunodeficiency System Damage
Netanya G. Sandler1, Steven E. Bosinger2, Jacob D. Estes1, Eli Botz2, Brandon F. Keele3, Jerome A. Langer4, Jeffrey D. Lifson5, Srinii S. Rao6, Gideon Schreiber7, Daniel C. Douek8
1Internal Medicine, University of Texas Medical Branch at Galveston, Galveston, TX, United States, 2Yerkes NHP Genomics Laboratory, Yerkes National Primate Research Center, Emory University, Atlanta, GA, United States, 3Leidos Biomedical Research, Inc, AIDS and Cancer Virus Program, Frederick National Laboratory for Cancer Research, Frederick, MD, United States, 4NIAID Vaccine Research Center, National Institutes of Health, Bethesda, MD, United States, 5Pharmacology, Robert Wood Johnson Medical School, Rutgers University, Piscataway, NJ, United States, 6Biological Chemistry, Weizmann Institute of Science, Rehovot, Israel

129 mir-422a: A Solitary MicroRNA Biomarker of Interferon-α Anti-HIV-1 Activity In Vivo
Mohamed Abdel-Mohsen1, Xinjia Deng1, Teri Liegler1, Andri Rauch1, Bruno Ledergerber1, Huldrych F.Günthard1, Joseph K. Wong2,3, Satish K. Pillai4,5,2, 6
1Medicine, University of California, San Francisco, San Francisco, CA, United States, 2Blood Systems Research Institute, San Francisco, CA, United States, 3Infectious Diseases, Ben University Hospital and University of Bern, Bern, Switzerland, 4Infectious Diseases and Hospital Epidemiology, University Hospital Zurich, University of Zurich, Zurich, Switzerland, 5Division of Infectious Diseases and Hospital Epidemiology, University Hospital Zurich, University of Zurich, Zurich, Switzerland, 6Medicine, San Francisco Veterans Affairs Medical Center, San Francisco, San Francisco, CA, United States

Session 0-10 Oral Abstracts
10:00 AM – 12:00 PM Ballroom B/C

CV and Other Complications

Moderators
Jason V. Baker, University of Minnesota, Hennepin County Medical Center, Minneapolis, MN, United States
Cristina Mussini, University of Modena and Reggio Emilia, Modena, Italy

130 Increased Arterial Inflammation Relates to High-Risk Coronary Plaque Morphology in HIV+ Patients
Ahmed Tawakol1, Markella V. Zanni1, Janet Lo2, Ezinne J. Ihenacho2, Allison Han2, Megan MacNabb3, Bryan Wai3, Udo Hoffmann4, Suhny Abbara1, Steven Grinspoon5
1Cardiology Division, Massachusetts General Hospital/Harvard Medical School, Boston, MA, United States, 2Program in Nutritional Metabolism, Massachusetts General Hospital/Harvard Medical School, Boston, MA, United States, 3Cardiovascular Radiology Division, Massachusetts General Hospital/Harvard Medical School, Boston, MA, United States

CROI 2014 18

Thursday, March 2014 • Oral Sessions
Arterial Inflammation in HIV as Measured by FDG-PET/CT Is Associated With Splenic Activity
Priscilla Y. Hsu1, Megan MacNabbi2, Rebecca Kaplan3, Elaine Nitta1, Steven Deeks1, Jeffrey Lifson2, Miguel Pampaloni3, Peter Ganzi4, Ahmed Tawakol5
1Cardiology, University of California San Francisco, San Francisco, CA, United States, 2Massachusetts General Hospital, Boston, MA, United States, 3University of California San Francisco, San Francisco, CA, United States

Repetitive Senescence of Circulating Osteogenic Cells and Low BMD in Perinatally Infected Men
John S. Manavelan, Stephen Arapdi, Jayesh Shah, Chiyuan A. Zhang, Marc Foca, Natalie Neu, Stavroula Kourteni, Michael T. Yin
Columbia University Medical Center, New York, NY, United States

High-Dose Vitamin D and Calcium Attenuates Bone Loss With ART Initiation: Results From ACTG A5280
Edgar T. Overtone1, Ellen S. Charn1, Todd T. Brown2, Pablo Tebas2, Grace A. McComsey3, Kathleen M. Melbourne4, Andrew Napoli5, Royce Hardin6, Heather J. Ribaudo7, Michael T. Yin8, ACTG A5280 Study Team
1University of Alabama School of Medicine, Birmingham, AL, United States, 2Harvard School of Public Health, Boston, MA, United States, 7The Johns Hopkins University, Baltimore, MD, United States, 8Hospita of the University of Pennsylvania, Philadelphia, PA, United States, 3Pediatrics, Case Western Reserve University, Cleveland, OH, United States, 4Gilead Sciences, Foster City, CA, United States, 5Virology, Bristol-Myers Squibb, Plainsboro, NJ, United States, 6Duke University Community Advisory Board, Durham, NC, United States, 7Harvard School of Public Health, New York, NY, United States

Rosuvastatin Improves Hip Bone Mineral Density But Worsens Insulin Resistance
Grace A. McComsey9, Ying-Jiang9, Kristine M. Eriandson10, Sara M. Debanne11
1Case Western Reserve University, Cleveland, OH, United States, 10University of Colorado Anschutz Medical Campus, Aurora, CO, United States

Effects of Tesamorelin On Hepatic Fat in HIV Patients: A Randomized, Placebo-Controlled Trial
Takara Stanley, Meghan Feldpausch, Jinhee Oh, Karen Branch, Martin Torriani, Steven Grinspoon
Massachusetts General Hospital, Boston, MA, United States

Proliferation of Cells With HIV Integrated Into Regulatory Genes Is a Mechanism of Persistence
Thor A. Wagner1, 2, Sherry McLaughlin1, 2, Kavita Gang1, Hannah Huang2, Sheila Styrczak3, James I. Mullins3, Lisa M. Fenkel2, 3
1University of Washington, Seattle, WA, United States, 2Seattle Children’s Hospital, Seattle, WA, United States, 3Fred Hutchinson Cancer Research Center, Seattle, WA, United States

Novel Ex Vivo Approaches Distinguish Effective and Ineffective Drugs for Reversing Latency In Vivo
Gregory M. Laird, Corin Bullen, Janet D. Siliciano, Robert F. Siliciano
The Johns Hopkins University School of Medicine, Baltimore, MD, United States

Effect of Vorinostat On Host Gene Expression in HIV Infected Patients On Antiretroviral Therapy
Khader Gheime1, Jeff Athler2, Julian Elliot3, Miranda Smith4, Fiona Wightman5, Anjil Soloman6, Miles Prince7, Steven Deeks1, Rafiek Sekaly8, Sharon Leewin9
1VGTI-F, Port Saint Lucie, FL, United States, 10Department of Medicine, University of California, San Francisco, CA, United States

Cyclophosphamide Enhances SB-728-T Engraftment To Levels Associated With HIV-RNA Control
Gary Blick1, Jay Lalezari2, Ricky Hsu1, Edwin DeJesus3, Trevor Hawkins4, Ronald Mitsuyasu5, Steven Deeks6, Gary Lee7, Winson Tang8, Dale Ando9
1Circle Care Center, Norwalk, CT, United States, 2Quest Clinical Research, San Francisco, CA, United States, 3Private Practice, New York, NY, United States, 4Orlando Immunology Center, Orlando, FL, United States, 5Southwest Care, Santa Fe, NM, United States, 6UCala David Geffen School of Medicine, Los Angeles, CA, United States, 7UCSF School of Medicine, San Francisco, CA, United States, 8Sangamo BioSciences, Richmond, CA, United States

Stimulation of Subdominant CTL Response Is Required for the Elimination of HIV-1 Latent Reservoir
Kai Deng, Mihaela Pertea, Liian Shang, Robert Siliciano
The Johns Hopkins University, Baltimore, MD, United States

Dendritic Cell-Based HIV Therapeutic Vaccine Increases Residual Viremia in Individuals On ART
Bernard J. Macatangay1, Mariam B. Lawani1, Sharon A. Riddell1, Nicole D. Wheeler1, Margaret A. Bedison1, Charles R. Rinaldo2, John W. Mellors3
1University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, 2Infectious Disease and Microbiology, University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA, United States

144LB HIV-1 Rebound Following Allogeneic Stem Cell Transplantation and Treatment Interruption
Timothy J. Henrich1, Emilie Vanhaeser2, Michael N. Sirignano3, Jonathan Z. Li4, Mathias Lichterfeld5, Francisco M. Marty6, Philippe Armand5, Robert J. Soiffer5, Marcus Attfield6, Daniel K. Kuritzkes4
1Brigham and Women’s Hospital, Cambridge, MA, United States, 2Brigham and Women’s Hospital, Cambridge, MA, United States, 3Department of Dermatology, Monash University, Melbourne, Australia, 4Department of Dermatology, Peter Macallum Hospital, Melbourne, Australia, 5Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States, 6Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, 7Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, United States

Session O-12 Oral Abstracts
10:00 AM – 12:15 PM Ballroom A

Persistence

Moderators
Nicolas Chomont, Vaccine and Gene Therapy Institute of Florida, Port St. Lucie, FL, United States
Mary Kearney, National Cancer Institute, Frederick, MD, United States

136LB Early Treatment in Acute SIV Infection Limits the Size and Distribution of the Viral Reservoir
Afam A. Okoye1, Mukta Rohankhedkar1, Matthew Reyes1, Joseph Clock1, Derick Duell1, Yoshinori Fukazawa2, Richard Lum1, Haesun Park1, Jeffrey D. Lifson1, Louis J. Picker1
1Vaccine & Gene Therapy Institute and the Oregon National Primate Research Center, Oregon Health & Science University, Beaverton, OR, United States, 2Frederick National Laboratory for Cancer Research, SAIC-Frederick, Inc, Frederick, MD, United States

CD4 T-Cell Subset Composition of HIV Reservoirs in Gut, Lymph Node, and Blood During HAART
Steven A. Yuksel1, 2, Teri Liefler1, Mohamed Abdel-Mohsen1, Elizabeth Sinclair1, Hiroyu Hatano1, Frederick Hecht1, Ma Sommeiuk1, Sarah Palmer1, 2, Steven G. Deeks1, Joseph K. Wong1, 2
1University of California San Francisco, San Francisco, CA, United States, 2San Francisco Veterans Affairs Medical Center, San Francisco, CA, United States, 3Karolinska Institute, Stockholm, Sweden, 4Westmead Millennium Institute for Medical Research, Sydney, Australia
Oral Sessions

145 Age-Disparate Relationships and HIV Incidence Amongst Rural South Africa Women
Guy Harling1, Marie-Louise Newell2,3, Frank Tanser1, Ichiro Kawachi1, SV Subramaniam1, Till Bärnighausen3
1Global Health and Population, Harvard School of Public Health, Boston, MA, United States, 2University of Southampton, Southampton, United Kingdom, 3Africa Centre for Health and Population Studies, Mbabubuka, South Africa

146 Introduction of HIV into Stable Heterosexual Couples in Rakai, Uganda Before and After ART
Mary K. Grabowski1, Justin Lester1, Fred Naluwoda2, Steve J. Reynolds3,4, Robert Ssekukuku1, Xiangrong Kong1, Geoffrey Kigozi2, Maria Wawer1,2, David Serrwadda1,3, Ronald H. Gray1,2
1The Johns Hopkins University, Baltimore, MD, United States, 2Epidemiology, Rakai Health Sciences Program, Kalisozo, Uganda, 3Medicine, The Johns Hopkins University, Baltimore, MD, United States, 4National Institutes of Health, Bethesda, MD, United States, 5Rakai Health Sciences Program, Kalisozo, Uganda, 6University of Makerere, Kampala, Uganda

147 One Year Outcomes Following Community-Based HIV Self-Testing: A Prospective Study in Malawi
Augustine T. Choko1, Peter MacPherson2,3, Emily L. Webb4, Helena Ball5, Rodrick Sambakunsi6, Aaron Mdo1, Simon D. Makombe7, Nicola Desmond1,2, Richard Hayes5, Elizabeth L. Corbett2,3
1Malawi Liverpool Wellcome Trust Clinical Research Programme, Blantyre, Malawi, 2Liverpool School of Tropical Medicine, Liverpool, United Kingdom, 3London School of Hygiene & Tropical Medicine, London, United Kingdom, 4HIV Unit, Ministry of Health, Lilongwe, Malawi

148 Community HIV Testing and Linkage To Care Reduces Population Viral Load in South Africa and Uganda
Ruanne V. Barnabas1,2,3, Heidi van Rooyen4, Elioda Turwessigwe4, Meighan Knorr1, Pam Mumana1, Hilton Humphries1, Bosco Turyamureeba1, James P. Hughes1,2, Jared Baeten1, Connie Celum3
1Global Health and Medicine, University of Washington, Seattle, WA, United States, 2Fried Hutchinson Cancer Research Center, Seattle, WA, United States, 3HIV/AIDS, STIs and Tuberculosis (HAST) Programme, Human Sciences Research Council, South Africa, 4Integrated Community Based Initiatives, Kabwohe, Uganda, 5Global Health and Epidemiology, University of Washington, Seattle, WA, United States, 6Global Health, Epidemiology and Medicine, University of Washington, Seattle, WA, United States

149 Enhanced HIV Surveillance To Evaluate the National Response To HIV/AIDS in Kenya
William Maina1, Davies Kimanga2, Ibrahim Mohammed3, Mamo Umuro1, Macdonald Obudho1, George Kichamu1, Patrick Mureithi1, Willis Akhwale1, Kevin M. De Cock1, Andrea A. Kim1

150 Unequal Benefits From ART: A Growing Male Disadvantage in Life Expectancy in Rural South Africa
Till Bärnighausen1,2,3,4 Abraham J. Herbst1, Frank Tanser1, Marie-Louise Newell1,2,3, Jacob Bor1,4
1Global Health and Population, Harvard School of Public Health, Boston, MA, United States, 2Africa Centre for Health and Population Studies, Mbabubuka, South Africa, 3University of Southampton, Southampton, United Kingdom, 4Department of International Health, Boston University School of Public Health, Boston, MA, United States

151 A New Paradigm for Evaluating the HIV Care Cascade
Margaret L. McNairy, Matthew Lamb, Batya Elul, Elaine Abrams, Wafaa El-Sadr, The Identifying Optimal Models of HIV Care in Africa Study
ICAP Columbia University, New York, NY, United States

152LB Moderate HIV Incidence and High ART Coverage in Rural Kwazulu-Natal: First Population-Based Survey
Helena Huerga1, Médécins Sans Frontières, Adrian Purcell2, Malika Bouhenia1, Jihané Ben Farhat1, Alex Weiss1, Lubbe Wiesner1, David Maman1, Jean-François Erdal1,2
1Epicentre, Paris, France, 2National Institute for Communicable Diseases of the NHLS, Johannesburg, South Africa, 3South African DST/NRF Centre of Excellence in Epidemiological Modelling and Analysis (SACEMA), Stellenbosch, South Africa, 4Division of Clinical Pharmacology, Cape Town, South Africa, 5Institut de Recherche pour le Développement, Montpellier, France

Session TD11 Themed Discussion
1:30 PM – 2:30 PM Room 309
Kaposi Sarcoma

Discussion Leader
Thomas S. Uldrick, National Cancer Institute, Bethesda, MD, United States

709 Guidelines On Kaposi’s Sarcoma Treatment: Results From Two Cochrane Systematic Reviews
Esther E. Freeman1, Charles Okwurudu1, Olututayo Gbabe2, Miriam Laker3, Philippa Easterbrook4, Toby Maurer1, Jeffrey Martin5
1Department of Dermatology, Harvard Medical School, Massachusetts General Hospital, Boston, MA, United States, 2Centre for Evidence-Based Health Care, Faculty of Medicine and Health Sciences, Stellenbosch University, Tygerberg, South Africa, 3Centre for Evidence-Based Health Care, Faculty of Health Sciences, Stellenbosch University, Tygerberg, South Africa, 4Department of Epidemiology and Biostatistics, University of California at San Francisco, San Francisco, CA, United States, 5HIV Department, World Health Organization, Geneva, Switzerland, 6Department of Dermatology, University of California at San Francisco, San Francisco, CA, United States

711 Kaposi Sarcoma in the Era of Combination Antiretroviral Therapy
Natascha Wyss, Matthias Egger, Julia Bohlius, Malignancy Working Group for COHERE in EuroCoord
Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland

710 Randomized Trial of Protease Inhibitor-Based Antiretroviral Therapy for Kaposi Sarcoma in Africa
Jeffrey Martin1, Miriam Laker-Oketta2,3, Victoria Walusansa4, Jackson Grem5, John Bennett1, Adrienne Mocello1, Toby Maurer1, Peter Hunt1, Andrew Kambugu1, Edward Mbude2,4
1University of California San Francisco, San Francisco, CA, United States, 2Infectious Diseases Institute, Kampala, Uganda, 3Uganda Cancer Institute, Kampala, Uganda, 4Uganda Virus Research Institute, Entebbe, Uganda

708 The Effect of Protease Inhibitor Use On Kaposi Sarcoma Incidence in a CART-Experienced Cohort
Elizabeth Chiao, Marc Kowalowski
Baylor College of Medicine, Houston, TX, United States

714 Indoleamine 2, 3-Dioxygenase (IDO) Activity as a Determinant of Kaposi Sarcoma in Africa
Helen Byakwaga1,2, Peter W. Hunt3, Miriam Laker-Oketta1,2, David V. Gilden1, Yong Huang1, Mwewa Mwetesiga1, Victoria Walusansa4, David R. Bangsberg1, Edward Mbude1, Jeffrey N. Martin1
1University of California San Francisco, San Francisco, CA, United States, 2Infectious Diseases Institute, Kampala, Uganda, 3Uganda Cancer Institute, Kampala, Uganda, 4Harvard Medical School, Massachusetts General Hospital, Center for Global Health, Boston, MA, United States
Session TD12 Themed Discussion

1:30 PM – 2:30 PM  

Ballroom A  
Pulmonary Complications of HIV Infection

Discussion Leader

Marshall J. Glesby, Weill Cornell Medical College, New York, NY, United States

775 HIV Infection and Related Biomarkers Are Independent Risk Factors for Radiographic Emphysema

Engi F. Attaia1, Matthew B. Goetz2, Maria C. Rodriguez-Barradas3, David Rimland3, Sheldon T. Brown4, Guy Soo Hoo5, Joon Kim6, Cheryl Wongtrakool4, Kathleen Akgun7, Kristina Crothers8

1Medicine, University of Washington, Seattle, WA, United States, 2Medicine, West Los Angeles Veterans Affairs Medical Center and David Geffen School of Medicine at University of California, Los Angeles, CA, United States, 3Department of Medicine, Atlanta Veterans Affairs Medical Center and VA Atlanta Health Care System, Atlanta, GA, United States, 4Medicine, Michael E. DeBakey Veterans Affairs Medical Center and Baylor College of Medicine, Houston, TX, United States, 5Medicine, Atlanta Veterans Affairs Medical Center and Emory University, Atlanta, GA, United States, 6Medicine, James J. Peters Veterans Affairs Medical Center and Icahn School of Medicine at Mt. Sinai, Bronx and NYC, NY, United States, 7Medicine, West Haven Veterans Affairs Medical Center and Yale University, West Haven, CT, United States

776 Factors Associated With Chronic Obstructive Pulmonary Disease in a High-Risk HIV-Infected Cohort

Alain Makinson1, Maurice Hayot2, Sabrina Eymard-Duverney3, François Raffi4, Laurence Thirard5, Fabrice Bonnaire6, Pierre Tattevin7, Sophie Aigrail8, Jacques Reynes3, Vincent Le Moing5

1ANRS EP48 HIV CHEST Study Team, 2Infectious and Tropical Diseases Department, University Hospital Montpellier 1, UMI 233, Montpellier, France, 3Department of Clinical Physiology, INSERM U1046, University Hospital Montpellier, Montpellier, France, 4UMI 233, IRD, University Montpellier 1, Montpellier, France, 5Infectious and Tropical Diseases Department, Nantes University Hospital, Nantes, France, 6Tourcoing University Hospital, Tourcoing, France, 7Internal Medicine and Infectious Diseases Department, University Hospital of Bordeaux, INSERM U1097, Bordeaux, France, 8Infectious Diseases and ICU, Pontchaillou University Hospital, Rennes, France

777 HIV Infection Increases Risk of Acute Exacerbations of COPD

Allison A. Lambert1, Gregory D. Kirk2, Jacquie Astemborski3, Shrutil H. Mehta4, M. Bradley Drummond1

1The Johns Hopkins University, Baltimore, MD, United States

778 Association of HIV Infection and Immune Activation With Decline in Lung Function

Kristina Crothers1, Carla V. Rodriguez2, Cheryl Wongtrakool3, Guy Soo Hoo3, Joon Kim3, Sheldon T. Brown1, David Rimland3, Maria C. Rodriguez-Barradas3, Matthew B. Goetz2, Amy C. Justice1

1Department of Medicine, University of Washington, Seattle, WA, United States, 2Medicine, West Los Angeles Veterans Affairs Medical Center and Emory University, Atlanta, GA, United States, 3Department of Medicine, West Los Angeles Veterans Affairs Medical Center and David Geffen School of Medicine at University of California, Los Angeles, CA, United States, 4Department of Medicine, Atlanta Veterans Affairs Medical Center and Emory University, Atlanta, GA, United States, 5Department of Medicine, West Los Angeles Veterans Affairs Medical Center and David Geffen School of Medicine at University of California, Los Angeles, CA, United States, 6Department of Medicine, James J. Peters Bronx Veterans Affairs Medical Center and and Icahn School of Medicine at Mt Sinai, New York, NY, United States, 7Department of Medicine, Michael E. DeBakey Veterans Affairs Medical Center and Baylor College of Medicine, Houston, TX, United States, 8Department of Medicine, Veterans Affairs Connecticut Healthcare System and Yale University, New Haven, CT, United States

Session TD13 Themed Discussion

1:30 PM – 2:30 PM  

Room 304  
Incidence Assays

Discussion Leader

Christine M. Rousseau, Bill and Melinda Gates Foundation, Seattle, WA, United States

1006 Performance of the Limiting-Antigen Avidity EIA for Use With Dried Blood Spot Specimens

Erin K. Rottinghaus1, Trudy Dobbs2, Bharat S. Parekh3, Yen T. Duong4

1Centers for Disease Control and Prevention, Atlanta, GA, United States

1008 Incorrect Identification of Recent HIV Infection Using a LAg-Avidity Assay in Adults in the US

Andrew F. Longoz1, Ron Brookmeyer2, Shrutil Mehta3, Greg D. Kirk4, Joseph B. Margolick5, Joelle Brown6, Thomas C. Quinn7, 8, Susan H. Eshlemann1, Olivier Laeyendecker1, 8

1Laboratory of Immunoregulation, Division of Intramural Research, National Institutes of Health, Baltimore, MD, United States, 2Department of Biostatistics, University of California Los Angeles, Los Angeles, CA, United States, 3Department of Epidemiology, The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, 4Department of Molecular Microbiology and Immunology, The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, 5Department of Epidemiology, University of California Los Angeles, Los Angeles, CA, United States, 6Department of Medicine, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, 7Department of Pathology, The Johns Hopkins University School of Medicine, Baltimore, MD, United States

1007 The Impact of HIV Subtype On Specificity of Cross-Sectional HIV Incidence Assays in Rakai, Uganda

Andrew F. Longoz1, David Serwadda2, 3, Fred Nauluguda4, Godfrey Kigozi5, Veronica Franco5, Ronald H. Gray3, 5, Thomas C. Quinn1, 5, Susan H. Eshlemann1, Olivier Laeyendecker1, 4

1NIAD, National Institutes of Health, Baltimore, MD, United States, 2Makerere University School of Public Health, Kampala, Uganda, 3Rakai Health Sciences Program, Rakai, Uganda, 4The Johns Hopkins University School of Medicine, Baltimore, MD, United States, 5The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

1005 Independent Evaluation of Predicate Incidence Assays for HIV Surveillance

Reshma Kassanjee1, Christopher Pilcher2, Sheila Keating3, Shelley Facente3, Matt Price4, Jeffrey Martin2, Susan Littler1, Alex Welte5, Michael Busch6, Gary Murphy7, Consortium for the Evaluation and Performance of HIV Incidence Assays (CEPHIA)

1The South African DST/NRF Centre of Excellence in Epidemiological Modelling and Analysis (SACEMA), Stellenbosch University, Stellenbosch, South Africa, 2University of California San Francisco, San Francisco, CA, United States, 3Blood Systems Research Institute, San Francisco, CA, United States, 4Department of Medical Affairs, International AIDS Vaccine Initiative (IAVI), New York City, NY, United States, 5Department of Medicine, University of California San Diego, La Jolla, CA, United States, 6Health Public England, London, United Kingdom

Session TD14 Themed Discussion

1:30 PM – 2:30 PM  

Room 312  
What We Learn From Bone Marrow Transplants

Discussion Leader

Paula M. Cannon, University of Southern California, Los Angeles, CA, United States

418 Impact of Systemic Cytotoxic Chemotherapy for Malignancies On HIV-1 Reservoir Persistence

Timothy J. Henrich1, Emily Hanhauser1, Jonathan Z. Li2, Andrea Helsay2, Jeremy S. Abramson3, Ayad Hamdan4, Philippe Armand5, Ann S. Lac真正的, Daniel R. Kunitzke1, 2

1Brigham and Women’s Hospital, Harvard Medical School, Cambridge, MA, United States, 2Brigham and Women’s Hospital, Cambridge, MA, United States, 3Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, 4Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, United States, 5Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, United States

417 Dynamics of HSPC Repopulation in Nonhuman Primates Revealed by a Decade-Long Clonal Tracking

Sanggu Kim1, Namshin Kim2, Angela Pressson3, Dong Sung An4, Robert E. Donahue5, Irvin S. Y. Chen1

1University of California, Los Angeles, Los Angeles, CA, United States, 2Korean Bioinformatics Center, Daejeon, Korea, Republic of, 3National Heart, Lung and Blood Institute, Bethesda, MD, United States

416 Targeting SIV Reservoirs via Autologous Hematopoietic Stem Cell Transplant in Rhesus Macaques

Maud Mavigner1, Benjamin Watkins2, 3, Benton O. Lawson4, Ann Chahroudi1, 2, Leslie S. Keenan2, 3, Guido Silvestri1
Session TD15 Themed Discussion

1:30 PM – 2:30 PM Room 311

CNS Viral Escape and Neuroinflammation on ART

Discussion Leaders

Dennis L. Kolson, University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA, United States
Scott L. Letendre, University of California San Diego, San Diego, CA, United States

447 CNS Outcomes of cART vs. cART plus Maraviroc and Raltegravir Intensification During Acute HIV

Victor Valcour1, Serena Spudich1, Napaporn Sailasuta2, Sukalaya Lerdum2, James L. K. Fletcher3, Eugene D. M. B. Kroon4, Peeraya Manipong4, Bonnie Sike5, Jerome Kire6, Jintanat Ananworanich7, on behalf of the SEARCH 010/ RV254 Study Group

1Memory and Aging Center, UCSF, San Francisco, CA, United States, 2Neurology, Yale University, New Haven, CT, United States, 3Huntington Medical Research Institutes, Pasadena, CA, United States, 4Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, 5SEARCH, The Thai Red Cross AIDS Research Center, Bangkok, Thailand, 6U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Springs, MD, United States, 7Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand

442 HIV-1 RNA Detection in CSF in ART-Treated Subjects With Incomplete Viral Suppression in Plasma

Sam Nightingale, the PARTITION Study Group

Institute of Infection and Global Health, University of Liverpool, Liverpool, United Kingdom

443 CSF Viral Escape in Patients Without Neurological Disorders: Prevalence and Associated Factors

Carmela Pinnetti1, Patrizia Lorenzini1, Federica Forticci1, Adriana Ammassari1, Rafaeilla Libertone2, Maria Letizia Giancola1, Maria Rosaria Capobianchi1, Carlo Federico Perno3, Andrea Antonini1

1National Institute for Infectious Disease, Rome, Italy, 2University of Rome, Rome, Italy

445 Cerebrospinal Fluid Viral Blips and Persistent Escape in HIV-Infected Patients On ART

Arvid Eden1, Lars-Magnus Andersson1, Dietmar Fuchs2, Lars Hagberg2, Staffan Nilsson3, Bo Svennerholm4, Aylin Yilmaz5, Henrik Zetterberg6, Magnus Gislen7

1University of Gothenburg, Gothenburg, Sweden, 2Innsbruck Medical University, Innsbruck, Austria, 3Chalmers University of Technology, Gothenburg, Sweden

446 Mitochondrial DNA Is Associated With Inflammation and Neurocognitive Deficits in HIV Infection

Josué Pérez-Santiago1, Sanjay R. Mehta2, Sara Gianella2, Rachel D. Schrier1, Mariana Cherny1, Susanna R. Var2, Tyler R. C. Day3, Miguel Ramirez-Gaona2, Davey M. Smith4, Scott L. Letendre5, 6

1Yerkes National Primate Research Center, Emory University, Atlanta, GA, United States, 2Department of Pediatrics, Emory University, Atlanta, GA, United States, 3Emory Transplant Center, Emory University, Atlanta, GA, United States, 4Yerkes National Primate Research Center, Emory University, Atlanta, GA, United States, 5University of Hawaii, Honolulu, HI, United States, 6SEARCH, The Thai Red Cross AIDS Research Center, Bangkok, Thailand

444 Early Monocyte Inflammation Among Treatment-Naïve Acute HIV-Infected Thai Subjects

Lishomwa C. Ndhlovu1, Mary Margaret Byron1, Guangxiang Zhang2, Duangthai Suthichok3, Somprathanthi Rattanamanee2, Rapeep Trichavaroj2, Nittaya Phanuphak1, Victor valcour1, Merlin Robb1, Jintanat Ananworanich7

1Hawaii Center for AIDS, University of Hawaii, Honolulu, HI, United States, 2University of Hawaii, Honolulu, HI, United States, 3SEARCH, The Thai Red Cross AIDS Research Center, Bangkok, Thailand, 4Airmed Forces Research Institute of Medical Sciences, Bangkok, Thailand, 5University of California San Francisco, San Francisco, CA, United States, 6US Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States, 7SEARCH, HIV-NAT, The Thai Red Cross AIDS Research Center, Bangkok, Thailand

POSTER SESSIONS

2:30 PM – 4:00 PM

(Use the Poster Abstract section of the Program at a Glance, page 37 to 106, for specific posters in each session)

Session P-A6 HIV Entry
Session P-A7 Factor Potpourri
Session P-B3 Viral Subtype: Expansion, Migration, and Recombination
Session P-C11 CD4/CD8, Aging, and Immune Senescence
Session P-C12 Mucosal CD4 and TH17 Cells
Session P-C13 In Vitro Studies
Session P-C14 Genomics and Endogenous Retroviruses
Session P-D5 Compartementalization
Session P-D6 New Themes in Host Control
Session P-E6 Human Vaccine Trial Results
Session P-E7 Immune Response To Infection
Session P-F7 Effect of ART on Persistence
Session P-F8 Immunology for Cure
Session P-F9 Toward A Cure...
Session P-G7 ART Effects on HAND and CNS Reservoirs
Session P-G8 CNS Inflammation, Immune Activation, and HAND Biomarkers
Session P-H4 New Clinical and Preclinical Formulations
Session P-J1 RCTs in Second-Line ART and Virologic Failure
Session P-J2 RCTs in First-Line ART in Treatment Naïve Patients
Session P-J3 ART Simplification, Intensification, and Switch Studies
Session P-K3 ART: Adherence and Retention
Session P-K4 Second-Line ART
Session P-K5 HIV-2
Session P-L5 Laboratory Detection of Drug Resistance and Tropism
Session P-L6 Cost Effectiveness Studies of ART and Drug Resistance Testing
Session P-N6 Acute HCV Infection: Pathogenesis
Session P-N7 HCV Infection and Cellular and Humoral Immune Responses
Session P-N8 HCV-Related Outcomes: Cardiac and Non-Liver
Session P-N9 HBV and HDV
Session P-N10 HEV
Session P-O5 Cervical Cancer, HPV, and HPV Vaccine
Session P-O6 Anal Cancer and HPV
Session P-P6 Statins and ARV Effects in HIV
Session P-P5 Antiretroviral Therapy, Lipids, and CVD
Session P-P4 Cost Effectiveness Studies of ART and Drug Resistance Testing
Session P-P3 Genomics and Endogenous Retroviruses
Session P-P2 In Vitro Studies
Session P-P1 Early Monocyte Inflammation Among Treatment-Naïve Acute HIV-Infected Thai Subjects
Session P-P0 HIV-1 RNA Detection in CSF in ART-Treated Subjects With Incomplete Viral Suppression in Plasma
Session P-Q9 Renal Disease: ART, Genetic Factors, and Long-Term Outcomes
Session P-Q8 Obesity: ART and Animal Models
Session P-Q7 Statins and ARV Effects in HIV
Session P-Q6 Obesity: ART and Animal Models
Session P-Q5 Cryptococcal Disease
Session P-Q4 Other than TB and Cryptococcal Disease
Oral Sessions

Session P-S2 HIV in Women: Pregnancy, Progression, Pap, and Bones
Session P-S3 Immune Mediators and Immune Activation in Women
Session P-S4 Immune Response To Vaccination in HIV+ Women
Session P-T7 Risk Factors for MTCT
Session P-T8 PMTCT Approaches: Implementation and Outcome
Session P-T9 ART Pharmacokinetics During Pregnancy and Breast Feeding
Session P-U6 Response To Early ART Initiation in Infants
Session P-U7 Co-Infections and Treatment Responses in Children and Adolescents
Session P-U8 Outcomes Among Adolescents – Perinatally and Behaviorally Acquired HIV Infection
Session P-W7 Disease Progression/Mortality
Session P-W8 Co-Morbidities
Session P-W9 Transmission/Risk Factors

Session S7 Symposium
4:00 pm – 6:00 pm Room 304
Interferon: Whatever Turns You On

Target audience: This session is directed to basic, translational, and clinical researchers interested in the role played by mechanisms of antiviral innate immunity — and, specifically, the type I interferons — in HIV-infected individuals in both protecting against virus replication and potentially inducing immunopathology in the host.

Level of knowledge: It is assumed that learners are familiar with the basic aspects of virology, immunology, and pathogenesis of HIV infection and AIDS.

Objectives: At the completion of the session, learners will be able to:
- Recognize the potential antiviral as well as pro-inflammatory roles of type I IFNs during HIV infection
- Understand the role of type I IFNs in HIV transmission and pathogenesis
- Describe the similarities and differences of the role played by type I IFNs in HIV and HCV infections

Conveners
Nina Bhardwaj, Icahn School of Medicine at Mount Sinai, New York, NY, United States
Michael M. Lederman, Case Western Reserve University, Cleveland, OH, United States

154 HIV-1 Evades Innate Immune Recognition Through Specific Co-Factor Recruitment
Greg J. Towers
University College London, London, United Kingdom

155 Interferon Treatments for Chronic Hepatitis C
Markus H. Heim
University Hospital Basel, Basel, Switzerland

156 Perturbing Interferon Signaling in SIV Infection
Daniel C. Douek
National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

157 Type 1 Interferon-Mediated Selective Pressure On HIV-1 Transmission
Persephone Borrow
University of Oxford, Oxford, United Kingdom

Session S8 Symposium
4:00 PM – 6:00 PM Room 311
The Road To Elimination: Preventing and Treating HIV Infection in Infants

Target audience: This session is directed to individuals interested in prevention of perinatal transmission and early antiretroviral therapy for HIV-exposed infants at high risk for perinatal transmission.

Level of knowledge: It is assumed that learners are familiar with the pathophysiology of perinatal HIV transmission, approaches to prevention of infant infection and HIV management of pregnant and breast-feeding women. In addition, learners should have a basic understanding of manifestations and treatment of HIV infection during infancy and early childhood.

Objectives: At the completion of the session, learners will be able to:
- Describe the rationale for and implementation experience with the Option B+ approach to prevention of perinatal HIV transmission
- Identify short- and long-term effects of antiretroviral exposure during pregnancy and breast-feeding
- Recognize new approaches to early diagnosis and treatment of HIV-exposed and -infected newborns

Conveners
Dalton C. Wamalwa, University of Nairobi, Nairobi, Kenya
Coceka N. Mnyani, University of the Witwatersrand, Anova Health Institute, Johannesburg, South Africa

158 Treatment of Pregnant and Breast-Feeding Women: Evidence and Rationale for Option B+
Saeed Ahmed
Baylor College of Medicine, Lilongwe, Malawi

159 Achievements and Challenges With Option B+ Implementation in the Field To Date
Edward Bitarakwate
Elizabeth Glaser Pediatric AIDS Foundation, Kampala, Uganda

160 No Free Rides: Consequences of Fetal & Infant ARV Exposure Among Children Remaining HIV Uninfected
Kathleen M. Powis
Harvard Medical School, Boston, MA, United States

161 Treatment of HIV-Infected Newborns: Why, When, and What To Start?
Ellen G. Chadwick
Northwestern University, Feinberg School of Medicine, Chicago, IL, United States
Session S9 Symposium
4:00 PM – 6:00 PM  Room 312

Intimate Infections: What’s Love Got To Do With It?

**Target audience:** This session is directed to clinicians and scientists interested in sexually transmitted infections affecting HIV-infected and -at risk persons.

**Level of knowledge:** It is assumed that learners are familiar with basic HIV epidemiology and sexually transmitted infections.

**Objective:** At the completion of the session, learners will be able to:

- Describe the epidemiology, clinical manifestations, association with HIV infection, and approaches to prevention and treatment of human papilloma virus (HPV), bacterial vaginosis (BV), meningococcus, and lymphogranuloma venerium (LGV)

**Conveners**
Christine Katlama, Pitié-Salpêtrière Hospital, Paris, France
Bernard Liautaud, GHESKIO Centers, Port-au-Prince, Haiti

162 Oral Human Papillomavirus (HPV): Epidemiology and Role in Oropharyngeal Cancer
Gypsyamber D’Souza
The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

163 Bacterial Vaginosis
Landon Myer
University of Cape Town, Cape Town, South Africa

164 Outbreak of Invasive Meningococcal Disease Among Men Who Have Sex With Men — New York City, 2010-2013
Alison D. Ridpath
New York City Department of Health and Mental Hygiene, New York, NY, United States

165 Lymphogranuloma venereum
David A. Lewis
National Institute for Communicable Diseases, Johannesburg, South Africa
Session P-A2 Poster Session

NK Cells in HIV Pathogenesis

273 NK Cell Subsets Responding To HIV-Infected Autologous CD4 T Cell in Protective KIR/HLA Genotypes
Irene Lisovsky1,2, Rujin Song3, Bertrand Lebouché4, Jean-Pierre Routy1,5, Julie Bruneau4, Nicole F. Bernardi1,7
1 Division of Experimental Medicine, McGill University, Montreal, QC, Canada;
2 Research Institute of the McGill University Health Centre, Montreal, QC, Canada;
3 Medicine Division of Experimental Medicine, McGill University, Montreal, QC, Canada;
4 Chronic Viral Infection Service, McGill University Health Centre, Montreal, QC, Canada;
5 Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CRCHUM), Montreal, QC, Canada;
6 Division of Experimental Medicine, McGill University, Montreal, QC, Canada

274 Siglec-7 Binds HIV-1 GP120 and Facilitates Infection of CD4+ T Cells and Macrophages
Stefania Varchetta1, Paolo Lusso2, Dalila Mele3, Stefania Paolucci2, Raffaello Cimbro2, Mauro Malnati2, Agostino Riva4, Renato Masera4, Mario U. Schmidt1, Phot Huy D. Le5, Michele Lisovsky1,2,5, Koya Arisoyu2, Hist Bennard, Divin Nyaver2, 3, Bertrand Lebouché4, Jean-Pierre Routy1,5, Julie Bruneau4, Nicole F. Bernardi1,7
1 Division of Infectious Diseases, Fondazione IRCCS Policlinico, Pavia, Italy;
2 Laboratory of Immunoregulation, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States;
3 Human Virology, San Raffaele Scientific Institute, Milan, Italy;
4 Department of Infectious Diseases, Amedeo di Savoia Hospital, Turin, Italy;
5 Department of Medical Biotechnologies and Translational Medicine, Humanitas Research Center and University of Milan, Rozzano (Milan), Italy

275 Monocyte and NK Cell Dysfunctional Responses To Mycobacteria During Chronic HIV-1 Infection
Melanie A. Gasper1, David R. Sherman1, Donald L. Sodora1
1 Seattle Biomedical Research Institute, Seattle, WA, United States;
2 Pathobiology Graduate Program, University of Washington, Seattle, WA, United States

276 Identification of a New Isomorph of MLL5: A Surrogate Marker of the CD4 Depletion in HIV-1
Vincent Viellard1, Florence Baychelier1, Alexis Sennepin1, Myriam Ermonval2, Patrice Debre1
1 INSERM UMR-S 945, Paris, France;
2 Département de Virologie, Institut Pasteur, Paris, France

277 Do KIR3DL1/HLA-B Combinations Influence ADCC Responses of HIV-1 Infected Slow Progressors?
Gamze Isitman1, Zoya Padasmi2, Pilar Zanoni1, Matthew Parsons1, Marianne Harrist3, Jean-Pierre Routy1,5, Cecile L. Tremblay4, Nicole F. Bernardi1
1 Division of Experimental Medicine, McGill University, Montreal, QC, Canada;
2 Research Institute of the McGill University Health Centre (RI-MUHC), Montreal, QC, Canada;
3 Medicine Division of Experimental Medicine, McGill University, Montreal, QC, Canada;
4 Microbiology and Immunology, University of Melbourne, Melbourne, Australia;
5 St Paul’s Hospital, Vancouver, BC, Canada;
6 Division of Hematology, Royal Victoria Hospital, Montreal, QC, Canada;
7 Centre de Recherche du Centre Hospitalier de l’Université de Montréal, Montreal, QC, Canada

278 CD8+ NK Cells in HIV-1 Infection Are Associated With Slower Disease Progression Towards AIDS
Fareed Ahmad1, Himnoh S. Hong1, J-Na Lu1, Marc Jakob1, Nupur Bhattacharj1, Johanna M. Eberhardt1, Benjamin A. Bollmann1, Reinhold E. Schmidt2, Dirk Meyer-Olson3
1 Clinic for Immunology and Rheumatology, Hannover Biomedical Research School (HBRSS), Medizinische Hochschule Hannover (HHN), Hannover, Germany;
2 Division of Immunology, Harvard Medical School, Southborough, MA, United States;
3 Clinic for Immunology and Rheumatology, Medizinische Hochschule Hannover (HHN), Hannover, Germany;
4 Rheumatologie, KVG Klinik in Bad Pyrmont Verwaltungs GmbH & Co Betriebs KG, Bad Pyrmont, Germany

Session P-C4 Poster Session
Tuesday March 4, 2014, 2:30 pm–4:00 pm  Exhibit Hall A

CD8 T-Cell Pathogenesis

279 HLA-B*35:05 Is a Protective Allele With a Unique Structure Amongst CRF01 AE-Infected Thais
Masahiko Mori1, Nuanjan Wichukchinda1, Reiko Miyahara1, Archawin Rojanawiwat2, Panita Pathipwanch5, Tomoyuki Maekawa2, Philip Goulder2, Michio Yasunami3, Koya Arisoyu2, Phot Huy D. Le5, Michele Lisovsky1,2,5, Koya Arisoyu2, Hist Bennard, Divin Nyaver2, 3, Bertrand Lebouché4, Jean-Pierre Routy1,5, Julie Bruneau4, Nicole F. Bernardi1,7
1 Department of Clinical Medicine, Nagasaki University, Institute of Tropical Medicine, Nagasaki, Japan;
2 Department of Paediatrics, University of Oxford, Oxford, United Kingdom;
3 Department of Medical Sciences, Ministry of Public Health, Nonthaburi, Thailand;
4 Day Care Centre, Lampang Hospital, Lampang, Thailand

280 Eomes and T-Bet Are Differentially Linked To CD8+ T-Cell Exhaustion in HIV Infection
Johanna Tauriainen1, Marcus Bugburg1, Takuya Yamamoto2, Bo Heijdenman3, Richard A. Koup1, Marianne Jansson4, Anders Sonnerborg5, Michael R. Betts6, Anna K. Carlsson1
1 Department of Laboratory Medicine, Institute of Clinical Microbiology, Karolinska Institutet, Stockholm, Sweden;
2 Immunology Laboratory, Vaccine Research Center, National Institute of Health, Bethesda, MD, United States;
3 Stockholm South General Hospital, Stockholm, Sweden;
4 Department of Microbiology, Tumor and Cell Biology (MTC), Karolinska Institutet, Stockholm, Sweden;
5 Department of Microbiology, University of Pennsylvania, Philadelphia, PA, United States

281 Increased Frequencies of HLA-G+ HIV-1-Specific Regulatory CD8 T Cells in HIV-1 Controllers
Selena Vignano1, Chun Li1, Jordi Negron1, Florence Pereyra2, Mathias Lichterfeld3, Xu Yu1
1 Ragon Institute of MGH, MIT, and Harvard, Cambridge, MA, United States;
2 Infectious Disease Division, Massachusetts General Hospital, Boston, MA, United States

282 CD8+CD28-CD127+CD39+ Treg: A New Biomarker for HIV Infection
Chiara Denton1, Daniela Fenoglio1, Alessia Parodi1, Francesca Kali1, Antonio Di Biagio1, Paolo Fraccaro1, Giancarlo Orofino1, Giovanni Cenderello1, Mauro Giacomini1,2, Gilberto Ficara1,3
1 University of Genoa, CEBR Genoa, Genoa, Italy;
2 Infectious Diseases, Sanremo Hospital, Sanremo, Italy;
3 Internal Medicine, University of Genoa, University of Genoa, Italy;
4 Infectious Diseases, IRCCS San Martino Hospital, University of Genoa, Italy;
5 Department of Informatics, Bioengineering, Robotics and System Engineering, DIBRIS, University of Genoa, Italy;
6 Infectious Diseases, Amedeo di Savoia Hospital, Turin, Italy;
7 Infectious Diseases, Galleria Hospital, Genoa, Italy

Session P-C5 Poster Session
Tuesday March 4, 2014, 2:30 pm–4:00 pm  Exhibit Hall A

Exhaustion Markers

283 Determinants of PD-1 Expression On CD4+ and CD8+ T Cells in Treated and Untreated HIV Disease
Leslie R. Cockerm1, Vivek Jain1, Elizabeth Sinclair1, David V. Glidden2, Wendy Hartogues1, Hiyori Hatano1, Peter W. Hunt1, Jeffery N. Martin1, Frederick M. Hecht1, Steven G. Deeks2
1 HIV/AIDS Division, University of California – San Francisco, San Francisco, CA, United States;
2 Department of Experimental Medicine, University of California – San Francisco, San Francisco, CA, United States;
3 Department of Epidemiology and Biostatistics, University of California – San Francisco, San Francisco, CA, United States

284 CD160 Is the Most Specific Co-Inhibitory Molecule Associated With CD8 T Cell Functional Impairment
Selena Vigan1, Rhiddhima Banga, Florence Bellanger, Alex Farina, Denis Comte, Giuseppe Pantaleo, Matthieu Perreau
Division of Immunology and Allergy, Lausanne University Hospital, Lausanne, Switzerland
285 Expansion of TIGIT-Expressing CD8+ T Cells Persists in Virally Suppressed HIV-1 Infection
Glen M. Chew1, Tsuyoshi Fujita2, Ravi Tandon1, Jeffrey N. Martin1, Steven Deeks1, Lisa Horwitz1, Nihal C. Ndhlovu1
1Tropical Medicine, University of Hawaii, Manoa, Honolulu, HI, United States, 2University of California San Francisco, San Francisco, CA, United States

286 PD-1 Expression Is Associated With Preserved CD4+ T Cell Homeostasis in Viremic Non-Progressors
Melicent C. Peck1, Elizabeth Sinclair1, Nicholas R. Klatt1, Lorrie Epling1, Jeffrey N. Martin1, Frederick M. Hecht1, Steven G. Deeks2, David Camerini1, Peter W. Hunt1
1Medicine, University of California San Francisco, San Francisco, CA, United States, 2Pharmaceuticals, University of Washington, Seattle, WA, United States, 3Epidemiology & Bio-statistics, University of California San Francisco, San Francisco, CA, United States, 4Medicine, University of California Irvine, Irvine, CA, United States

287 PD-1 Homolog Expression Regulates Spontaneous Cytokine Production in HIV Infection
Premi Bharaj1, Harenda S. Chahar2, Lizette Rodarte3, Ogechika Alozie1, Manjunath Swamy1, Premila Shankar1
COEID, Texas Tech University, El Paso, TX, United States

Session P-C6 Poster Session
Wednesday March 5, 2014, 2:30 pm–4:00 pm Exhibit Hall A

Clades and Pathogenesis

288 HIV Virulence Has Not Increased in the UK Subtype B Epidemic
Emma B. Hodcroft1, Jarred Hatfield2, Esther Fearnhaim3, Andrew Phillips4, David Dunn5, Deenan Pillay1, David Leigh-Brown1, UK HIV Drug Resistance Database
1Institute of Evolutionary Biology, University of Edinburgh, Edinburgh, United Kingdom, 2Department of Zoology, University of Oxford, Oxford, United Kingdom, 3MRC Clinical Trials Unit, London, United Kingdom, 4Research and Population Health, University College London, London, United Kingdom, 5Research Department of Infection, University College London, London, United Kingdom

289 Subjects Infected With Clade C-Containing HIV Exhibit Higher CD4+ T Cell Activation
Prescilla R. Costa1, Wendy Hartogensis2, Ricardo S. Díaz3, Peter Bacchetti4, Rick Hecht1, Breno R. Santos1, AMPLIAR study team1, Esper G. Kallas1, Chris Pilcher1
1Medicina, Universidade de São Paulo, São Paulo, Brazil, 2University of California, San Francisco, CA, United States, 3Hospital Concepción, Ponte Alegre, Brazil

Session P-C7 Poster Session
Wednesday March 5, 2014, 2:30 pm–4:00 pm Exhibit Hall A

Coremarker Studies

290 Telomere Length Predicts Immunological Recovery in Older HIV Patients Treated With cART
Jose-Ramon Blanco1, Inmaculada Jarrín2, Alfredo Martínez3, Eva Siles4, Ana Cañedo5, Felix Gutierrez6, Jorge del Romero7, Jesus Santos8, Santiago Moreno9, CoRIS
1Hospital San Pedro-CIBIR, Logroño, Spain, 2ISCIII, Madrid, Spain, 3Oncología-CIBIR, Logroño, Spain, 4Department of Experimental Biology, University of Jaen, Jaen, Spain, 5Hospital Elche-Elche, Spain, 6Sandoval, Madrid, Spain, 7Hospital Virgen de la Victoria, Malaga, Spain, 8Hospital Ramón y Cajal, Madrid, Spain

291 The Clinical Impact of Viral Load Copy Years in Antiretroviral- Naive HIV Serocounters
Matthias an der Heiden1, Alexander Zoufaly1, Caroline Sabin1, Jan van Lunzen1, Hane-Jürgen Stellbrink1, Barbara Gensheimer-Bartmeyer2, Philippe Vanhemel1, Santiago Perez-Collazo2, on behalf of CASCADE Collaboration
1EuroCoord

292 Interleukin-32: Expression, Interaction With IFN, and Clinical Significance in HIV-1 Infection
Carolina Scagnolari1, Katia Montenelone1, Carla Selvaggi1, Francesca Falaschi1, Pierluigi Di Maio1, Ivano Mezzaroma1, Gabriella d’Ettore1, Ombretta Turritani1, Guido Antinelli1
1Molecular Medicine, Sapienza University of Rome, Rome, Italy, 2Department of Clinical Medicine, Sapienza University of Rome, Rome, Italy, 3Department of Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy

293 TNFα in Viral Control and Early Disease Progression in Patients With HIV-1 Infection
Sagar A. Vaidya1,2, Christian Komer1, Michael Srinigaran1, Molly Amero1, Sue Bazner1, Jenna Rychert1, Todd Allen2, Eric S. Rosenberg3, Ronald J. Bosch4, Marcus Altfeld5
1The Ragon Institute of MGH, MIT, and Harvard, Cambridge, MA, United States, 2Division of Infectious Diseases, Massachusetts General Hospital, Boston, MA, United States, 3Harvard School of Public Health, Boston, MA, United States, 4Department of Viral Immunology, Heinrich Pette Institute, Hamburg, Germany

294 Monocyte Activation Markers in HIV Infected Subjects: A Biomarker for HIV Immunotherapy
Joumana Zeldan1, Elizabeth Sinclair1, Gary Lee2, Shelley Wang2, Martin Geldiol3, Geoff Nicholl4, Winsong Tang5, Steven Deeks1, Dale Ando1, Ratilak-Pierre Sekaly1
1VGTI Florida, Port St. Lucie, FL, United States, 2UCSF, San Francisco, CA, United States, 3Sangamo Biosciences, Richmond, CA, United States

295 Down-Regulation of CD39/CD73 On B Cells of HIV Patients Coincides With a Disturbed Ig Class Switch
Eun-Seong Kim1, Ilona Töth1, Claudia Reise1, Johanna Eberhardt1, Silke Kummer1, Ansgar W. Lohe1, Friedrich Haag1, Jan van Lunzen1, Julian Schulte zur Wiesch1
1I, Department of Internal Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, 2Institute of Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Session P-C8 Poster Session
Wednesday March 5, 2014, 2:30 pm–4:00 pm Exhibit Hall A

Elite Controllers

296 Transcriptional Signatures of CD4 T Cell Subsets and Control of HIV Reservoirs in Elite Controllers
Adele de Masson1, Armos Kirlovskiy2, Rima Zoorob3, Veronica Averttand-Fenoel1, Veronica Morin1, Anne Oudin1, Benjamin Descours1, Christine Rouzou1, Brigitte Autran2, the ALT ANRS-Co5 Study Group
1Inmunovirologie, Université Pierre et Marie Curie - Paris 6, UMR S945, Laboratory Immunology and Infection, INSERM, U945, Laboratory Immunology and Infection, Paris, France, 2Inmunovirologie, Paris-Descartes University, Sorbonne Paris-Cité, EA 3620, Virology Laboratory, Necker Enfants-Malades Hospital, Paris, France

298 Elite Suppressor CD4+ and CD8+ T Cells Suppress Viral Replication in Monocyte-Derived Macrophages
Victoria E. K. Walker-Sperling1, Robert W. Buckheit2, Robert F. Siliciano3,4, Joel N. Blankson1
1Immunology Graduate Program, The Johns Hopkins School of Medicine, Baltimore, MD, United States, 2National Cancer Institute, Frederick, MD, United States, 3Department of Medicine, The Johns Hopkins School of Medicine, Baltimore, MD, United States, 4Howard Hughes Medical Institute, Chevy Chase, MD, United States

299 Effective Control of Virus Replication in HIV-1 Elite Controllers by Active SAMHD1
Eduardo Páuls1, Alba Ruiz1, Beatriz Mothe1, Manel Crespo2, Menéndez-Arias Luis3, Bonaventura Clotet1, Oliver T. Keppler1, Francesc Posas4, Christian Brander1, José A. Esté1
1ICrea AIDS Research Institute, Hospital Germans Trias i Pujol, Universitat Autònoma de Barcelona, Badalona, Spain, 2Infectious Diseases, Hospital Universitari Vall d’Hebron, Barcelona, Spain, 3Centre de Biologia Molecular Severo Ochoa, Consejo Superior de Investigaciones Científicas, Universidad Autònoma de Madrid, Madrid, Spain, 4Institute of Medical Virology, University of Frankfurt, Frankfurt, Germany, 5Cell Signaling Unit, Departamento de Ciències Experimentals i de la Salut, Universitat Pompeu Fabra, Parc de Recerca Biomèdica de Barcelona, Barcelona, Spain, 6Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain
Session P-C9 Poster Session

Wednesday March 5, 2014, 2:30 pm–4:00 pm  Exhibit Hall A

Pathogenesis: Insights From Clinical Trials

300 Effect of Raltegravir Intensification in the Cytokine Profile of Treated HIV+ Individuals
Marta Massanella1, Josep M. Liblert2, Silvia Marfil2, Maria C. Puertas3, Jordi Puig4, Eugenia Negredo5, Douglas D. Richman6,7, Javier Martinez-Picado1,2, Bonaventura Clotet1,2, Julita Blanco1,2
1Pathology, University of California San Diego, La Jolla, CA, United States, 2Lluitra contra la Sida Foundation, Badalona, Spain, 3AIDS Research Institute IRS/ICaiA, Institut d’Investigació en Ciències de la Salut Germans Trias i Pujol, IGTP, Badalona, Spain, 4University of California San Diego, La Jolla, CA, United States, 5Veterans Affairs San Diego Healthcare System, La Jolla, CA, United States, 6University of Southern California Keck School of Medicine, Los Angeles, CA, United States, 7Veterans Affairs San Diego Healthcare System, La Jolla, CA, United States

301 Analyses of HIV-1 Viral Dynamics During Treatment With a Regimen Including an Integrase Inhibitor
Jeremie Guedj1, Ruy Ribeiro2, Adriana Andrade1,3, Susan L. Roenkrantz1,2, Darlene Lu2, Douglas Richman3, Mathew Strain4, John Mellors2, Daniel R. Kuritzkes1, Alan S. Perelson2
1UMR-0738, INSERM, Paris, France, 2Theoretical Biology and Biophysics, Los Alamos National Laboratory, Los Alamos, NM, United States, 3The Johns Hopkins University, Baltimore, MD, United States, 4Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, United States, 5Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, United States, 6University of California, San Diego, San Diego, CA, United States, 7School of Medicine, University of Pittsburgh, Pittsburgh, PA, United States, 8Brigham and Women’s Hospital, Boston, MA, United States

302 Characterization of Functional Profile of HIV-Specific CD4+ T Cells in VISCONTI Group of Patients
Assia Samri1,2, Charline Bacchus1, Laurent Hocqueloux1, Asier Saiz-Creion1, Amandine Emarre1, Christine Rouloz1, Brigitte Autran1, and VISCONTI ANRS Study
1Immunology, UPMC Univ Paris 06, UMR-S945, Laboratory Immunity and Infection, INSERM, U945, Laboratory Immunity and Infection, Paris, F-75013, France, Paris, France, 2Innate Immunology, Infectious and Tropical Diseases Department, Regional Hospital Center, Orleans, France, Orleans, France, 3Immunology, Institut Pasteur, Unité de Régulation des Infections Rétrovirales, Paris, France, Paris, France, 4Virology, Virology Laboratory, René Descartes University, EA 3620, Necker Enfants-Malades Hospital, Paris, France

303 Immune Activation and Defective pTFFs Are Associated With Impaired Immunity in Aging HIV+ Persons
Varghese K. George1, Sureesh Pallikkuth1, Anita Parmigiani1, Maria L. Alcaide1, Margaret Fisch1, Savita Pathwa1
1Microbiology and Immunology, University of Miami, Miami, FL, United States, 2Human & Molecular Genetics, Virginia Commonwealth University, Richmond, VA, United States

304 Fresh Cohort: Acute HIV-1 Infection in Cohort of High Risk HIV Negative Women in KZN, South Africa
Krista Dong1,2, Amber Moodley1, Thumuli Nduqulu1,3, Bruce Walker1,4
1Ragon Institute, Massachusetts General Hospital, Boston, MA, United States, 2Harvard Medical School, Boston, MA, United States, 3University of KwaZulu-Natal, Durban, South Africa, 4The Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States

305 Vitamin D Significantly Changes the Immune Transcriptome and Augments CD4 Recall Responses in HIV
Raskit Lachmann1, Margaret-Anne Bevan2, Sangini Kim1, Nichna Patel1, Riddhima Banga1, Nagasuma Chandra1, Sudha Rad4, Catherine Hawrowycz1, Annapurna Vyakarnam1, Barry Peters1
1Infectious Diseases, Kings College London, London, United Kingdom, 2GU Medicine and HIV, Guy and St Thomas’ Hospital Trust, London, United Kingdom, 3Indian Institute of Science, Bangalore, India, 4Genotypic Technology Limited, Bangalore, India, 5Division of Asthma, Allergy & Lung Biology, Kings College London, London, United Kingdom

306 Impact of Methamphetamine Use On Immunologic and Virologic Markers During Suppressive ART
Marta Massanella1, Sara Gianella1, Douglas D. Richman1,2, Susan J. Little1, Constance B. Benson1, Eric S. Daar1, Michael D. Dubé1, Richard H. Haubrich1, Davey M. Smith1,2, Sheldon R. Morris1, the CCTG 592 Team
1University of California San Diego, La Jolla, CA, United States, 2Veterans Affairs San Diego Healthcare System, La Jolla, CA, United States, 3Los Angeles Biomedical Research Institute, Torrance, CA, United States, 4University of Southern California Keck School of Medicine, Los Angeles, CA, United States, 5Veterans Affairs San Diego Healthcare System, La Jolla, CA, United States

307 Vitamin D-Receptor Gene Polymorphisms: Association With Virologic Failure and Mortality
Simbarashe Takura1,2, Lynne McNamara3, Tobias Chinwa4, Ian Sanne5, Adrian R. Martineau1, Patrick A. MacPhail6
1Centre for HIV and STIs, National Institute for Communicable Diseases, NHLS, Johannesburg, South Africa, 2Department of Internal Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, 3Clinical HIV Research Unit, Department of Internal Medicine, University of the Witwatersrand, Johannesburg, South Africa, 4School of Public Health, University of the Witwatersrand, Johannesburg, South Africa, 5Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom

308 Statins Use Is Associated With Greater CD4 Gains in HIV-Infected US Veterans
Henning J. Drechsler1,2,4, James Cutrell1,2, Pablo Teces2,3, Roger Bedimo1,2
1Medicine, North Texas VA Health Care System, Dallas, TX, United States, 2Medicine, UT-Southwestern Medical Center of Medicine, Dallas, TX, United States, 3University of California, San Diego, San Diego, CA, United States, 4Medicine, University of Pennsylvania, Philadelphia, PA, United States

309 Maraviroc Intensification in HIV-Infected Patients Induces Increased CCR5 Expression On T Cells
Assia Samri1, Gaet Mouillot1,2, Christina Psomas1, Melanie Lavenu3, Selma Trabelsi1, Lisa Cuzin1, Pierre Corbeau1, Brigitte Autran1, Philippe Fandre1,2
1Immunology, UPMC Univ Paris 06, UMR-S945, Laboratory Immunity and Infection, INSERM, U945, Laboratory Immunity and Infection, Paris, F-75013, France, Paris, France, 2Innate Immunology, Infectious and Tropical Diseases Department, Regional Hospital Center, Orleans, France, Orleans, France, 3Immunology, Institut Pasteur, Unité de Régulation des Infections Rétrovirales, Paris, France, Paris, France, 4Virology, Virology Laboratory, René Descartes University, EA 3620, Necker Enfants-Malades Hospital, Paris, France

Session P-C10 Poster Session

Wednesday March 5, 2014, 2:30 pm–4:00 pm  Exhibit Hall A

Innate Immunity and Pathogenesis

237 CD161+Vc7.2+IL18R+ MAIT Cells Are Reduced in HIV Infection Regardless of the Disease Status
Johanna M. Eberhard1, Philip Hartung2, Achwin Balagopal1, Clara Lehmann1, Dominik Ebert1, Ilona Toth1, Silke Kummer1, Reinhold E. Schmidt1, Jan van Lunzen1, Julian Schulze zur Wiesch2
1Infectious Diseases Unit, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, 2Department of Oral and Maxillofacial Surgery, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, 3Department of Medicine, The Johns Hopkins University, Baltimore, MD, United States, 4Department of Medicine, University Medical School Cologne, Germany, 5Clinic for Immunology and Rheumatology, Hannover Medical School, Hanover, Germany

238 HIV-1 Alters Plasmacytoid Dendritic Cell Phenotype and Function by Modulating ILT Receptors
Adel Benlahrech1, Amina Yasmin1, Peter Keller2, Nesrina Imami3, Steven Patterson4
1Immunology, Imperial College London, London, United Kingdom, 2Medicine, Imperial College London, London, United Kingdom

239 Innate Immune Reconstitution With Viral Suppression in HIV-1 Infection
Eileen Culley1,2, Ainsley Lockhart1, Chelsey Musante1,2, JI Chang1, Molly Amero1, Eric T. Rosenburg1, Ronald J. Bosch2, Marcus Attfield3,4
1Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States, 2Division of Infectious Disease, Brigham and Women’s Hospital, Boston, MA, United States, 3Division of Infectious Disease, Massachusetts General Hospital, Boston, MA, United States, 4Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, United States, 5Institut Pasteur Lille, Leibniz Institute for Experimental Virology, Hamburg, Germany
Session P-C12 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM  Exhibit Hall A

Mucosal CD4 and Th17 Cells

244 Severe Depletion of Lung CD4 T Cells During HIV Infection Impairs Alveolar Macrophage Function
Bjorn Corleis1, Maud Deruaz2, Melis N. Anahatar1, Gregory Olson1, Brittany Bowman1, Vladimir Vrbanac1, Andrew M. Tager2, Douglas S. Kwon1
1Ragon Institute of MGH, Harvard and MIT, Cambridge, MA, United States, 2Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States

245 Impaired IL-23 Signalling and Th17 Dysfunction in HIV Infection
Jason R. Fernandes1, Ashok Kumar2,3, Jonathan B. Angel2,3
1Chronic Diseases, The Ottawa Hospital Research Institute, Ottawa, ON, Canada, 2Pathology, Children’s Hospital of Eastern Ontario Research Institute, Ottawa, ON, Canada, 3Faculty of Medicine, University of Ottawa, Ottawa, ON, Canada

246 Th17 and Tregs at Early HIV Infection Influence Disease Progression and HIV Specific CD8+ Responses
Juliana Falivene1, Yanina A. Ghiglione1, Natalia L. Laufer2,3, Maria E. Socías4, María J. Ruiz1, Pedro H. Cahn2,3, Omar Sued2,3, Horacio Salomón1, Gabriela Turk1, María M. Gherardi1
1Instituto de Investigaciones Biomédicas in Retrovirus y SIDA, UBA-CONICET, Buenos Aires, Argentina, 2Pathology, Children’s Hospital of Eastern Ontario Research Institute, Ottawa, ON, Canada, 3Faculty of Medicine, University of Ottawa, Ottawa, ON, Canada

247 Profound Lung CD4+ T-Cell Depletion in HIV-Associated Chronic Obstructive Pulmonary Disease
Iulia Popescu1, M. Bradley Drummond1, Lucie Gama2, Christian Merioz2, Robert Wise3, Janice Clements2, Gregory D. Kirk4, John F. McDyer5
1Medicine, University of Pittsburgh, Pittsburgh, PA, United States, 2Medicine, The Johns Hopkins University, Baltimore, MD, United States, 3School of Public Health, The Johns Hopkins University, Baltimore, MD, United States

248 Site Specific HIV-Infection of Th17 Cells in the Human Female Reproductive Tract
Marta Rodriguez-Garcia1, Fiona D. Barr2, John V. Fahey3, Charles R. Wira4
1Physiology and Neurobiology, Geisel School of Medicine at Dartmouth, Lebanon, NH, United States

Session P-C13 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM  Exhibit Hall A

In Vitro Studies

252 IL-15 Induces Id2 To Drive Effector Differentiation of CD8 T Cells and EM Cells While Maintaining CM Pools
Alessandra Noto1, Francesco A. Procopio2, Julien van Grevenynghe3, Cheryl Cameron1, Courtney Steff1, Amir Sabnis5, Hiroshi Takata6, Franck Duyup7, Jeff Ahlers1, Rafick-Pierre Sekaly8
1Vaccine and Gene Therapy Institute, PORT SAINT LUCIE, FL, United States, 2Lady Davis Institute, McGill University, Montreal, QC, Canada

253 Double Stranded RNA Stimulates IL-1β Secretion in Cervical Epithelial Cells via the Inflammasome
Melis N. Anahatar1, Maud Deruaz2, Andrew M. Tager2, Douglas S. Kwon3
Ragon Institute, Massachusetts General Hospital, Cambridge, MA, United States

254 Alpha-Defensins Modulate HIV Transcytosis: Role of STI-Mediated Enhancement of HIV Transmission
Kimyata Valere1, Aprille Rapista2, Alison J. Quayle3, Wuyan Lu4, Elseo Eugenio1, Theresa Chang3
1First Department of Internal Medicine, University of Cologne, Cologne, Germany, 2Institute for Medical Microbiology, Immunology and Hygiene, University of Cologne, Cologne, Germany, 3Institute of Human Virology, University of Maryland School of Medicine, Baltimore, MD, United States

255 Exposure To IFNα Leads To Generation of IL-10-Producing Tr1 Cells
Clara Lehmann1, Kristina Koch1, Nora Koch2, Pia Hartmann2,3, Gerd Fältkenheuer1, Fabio Romero1
1First Department of Internal Medicine, University of Cologne, Cologne, Germany, 2Institute for Medical Microbiology, Immunology and Hygiene, University of Cologne, Cologne, Germany, 3Institute of Human Virology, University of Maryland School of Medicine, Baltimore, MD, United States
256  TNF Drives Foam Cell Formation by Monocytes From HIV+ Donors in an In Vitro Atherosclerosis Model
Anna Maiya1, Candida F. Pereira2, 3, Thomas A. Angeltick4, 5, Jing-Ling Zhou1, William A. Muller1, Anna C. Heaps4, 5, Suzanne M. Crowe1, 3, Anthony Jaworowski1, 3
1Burnet Institute, Melbourne, Australia, 2Centre for Biomedical Research, Burnet Institute, Melbourne, Australia, 3Department of Infectious Diseases, Monash University, Melbourne, Australia, 4School of Applied Sciences, RMIT University, Melbourne, Australia, 5Northwestern University, Chicago, IL, United States, 6Department of Infectious Diseases, Monash University, Melbourne, Australia

257  HIV-Altered mRNA Expressions of Type 1 IFN Pathway Related To Activation/Exhaustion in CD4+ T Cells
Chi-Lin Lee1, Erik Serrao2, 3, Ton I. Frederik1, Chia-Hao Wang4, Andrea Kovacs5
1Department of Pediatrics, Keck School of Medicine, University of Southern California, Los Angeles, CA, United States, 2Harvard Medical School, Boston, MA, United States, 3Pharmacology and Pharmaceutical Sciences, University of Southern California, Los Angeles, CA, United States

258  Dysfunctional High Density Lipoprotein Directly Upregulates T Cell Activation in HIV-1 Infection
Theodoros Kelesidis, Judith Currier, Diana Huynh, Sangeun Park, Hwee Ng, Otto O. Yang
Medicine, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, United States

259  Dysfunctional High Density Lipoprotein Directly Reduces HIV-1-Specific Antiviral Responses
Theodoros Kelesidis, Judith Currier, Diana Huynh, Sangeun Park, Hwee Ng, Otto Yang
Medicine, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, United States

Session P-C14 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM  Exhibit Hall A
Genomics and Endogenous Retroviruses

260  HLA Gene Loci Associated With HIV Load in CSF and Blood Plasma in the CHARTER Cohort
Benjamin B. Gelman1, Sunil K. Ahuja2, Ronald J. Ellis3, Scott Letendre4, Christina M. Marra2, Justin McArthur5, Susan Morgello1, David B. Clifford6, Igor Grant7, Florin Vaida8, The CHARTER GROUP
1Pathology, University of Texas Medical Branch, Galveston, TX, United States, 2Medicine, University of Houston Health Science Center at San Antonio, San Antonio, TX, United States, 3Neurology, University of California - San Diego, San Diego, CA, United States, 4Medicine, University of California - San Diego, San Diego, CA, United States, 5Medicine, University of Washington, Seattle, WA, United States, 6Medicine, The Johns Hopkins University, Baltimore, MD, United States, 7Neurology, Icahn School of Medicine at Mount Sinai, New York, NY, United States, 8Medicine, Washington University, Saint Louis, MO, United States, 9Psychiatry, University of California - San Diego, La Jolla, CA, United States, 10Family and Preventive Medicine, University of California - San Diego, San Diego, CA, United States

261  GUAVAh: A Compendium of Host Genetic Data in HIV Biology and Disease
Istvan Bartah3, 4, Paul J. McLaren1, 5, Angela Cuffif6, Jacques Fellay6, 7, Amalio Telenti1
1École Polytechnique Fédérale De Lausanne, Lausanne, Switzerland, 2Institute of Microbiology, University Hospital Lausanne, Lausanne, Switzerland

262  HIV-1 Infection Leads To Increased Expression of HML-2 Proviruses In Vivo But Not Virion Production
Neenu Bhardwaj1, Frank Maldarelli1, John Mellors2, John M. Coffin3
1Tufts University, Boston, MA, United States, 2National Cancer Institute, Frederick, MD, United States, 3University of Pittsburgh, Pittsburgh, PA, United States

263  Exome Sequencing To Evaluate the Impact of Rare Coding Variation On HIV-1 Control
Paul J. McLaren1, Patrick R. Shea2, David B. Goldstein1, Jacques Fellay2
1Life Sciences, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, 2Center for Human Genome Variation, Duke University School of Medicine, Durham, NC, United States

Session P-D1 Poster Session
Tuesday March 4, 2014, 2:30 PM–4:00 PM  Exhibit Hall A
It's All About the Gut

310  Increased Immune Activation After Gut Permeabilization in SIV-Infected African Green Monkeys
Jan Kristoff1, Thaïdra Gaufri1, Rajevay Gautam2, Dongchu Ma1, Jacob Estes4, Russell Tracy1, Cristian Apetrei2, Steve Nelson3, Gregory Bagby4, Ivona Pandrea5
1Center for Vaccine Research, University of Pittsburgh, Pittsburgh, PA, United States, 2ULCA, Los Angeles, CA, United States, 3Center for Vaccine Research, NIAID/NIH, Bethesda, MD, United States, 4WCI/NIAID, Frederick, MD, United States, 5University of Vermont, Colchester, VT, United States, 6Louisiana State University, New Orleans, LA, United States

311  Breaches in Colonic Claudin-4 Expression Correlate With T-Cell Activation in HIV-1 Infection
Louise Greathread1, Anna Mroz4, Hiromi Kudo4, Brian Gazzard2, Mark Nelson2, Robert D. Goldin1, Alan Steel1, Peter Kelleher1
1Imperial College, London, United Kingdom, 2Chelsea and Westminster Hospital NHS Trust, London, United Kingdom

312  Rapid Gut-Homing of Plasmacytoid Dendritic Cells During Acute SIV Infection
Haiying Li, Jacqueline Gillis, R. Keith Reeves
NEPRC, Harvard Medical School, Southborough, MA, United States

313  CCR6+ and CD161+ CD4 T Cell Loss Contributes To the Pathogenesis of SIV Infection in Rhesus Macaques
Colleen S. McGary1, Luca Mici3, Emily S. Ryan1, Maria J. Buzari3, Amy Shaw1, Mathias Lichterfeld2, Guido Silvestri3, 4, Aftab A. Ansari3, Mirko Paliardini1, 5
1Department of Microbiology and Immunology, Emory University, Atlanta, GA, United States, 2Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States, 3Department of Pathology and Laboratory Medicine, Emory University, Atlanta, GA, United States

314  SIV Vaccine Controllers Prevent Aberrant Accumulation of Follicular CD4 T Cells in Rectal Mucosa
Geetha H. Mylvaganam1, 2, Vijayakumar Velu1, 3, Jung-Joo Hong4, 5, Shanmugalakshmi Sadagopan1, 2, Suifen Kwa3, 4, Rahul Basu3, 5, Benton Lawson4, Francois Villinger6, 7, Rama R. Amara8, 9
1Microbiology and Immunology, Emory University School of Medicine, Atlanta, GA, United States, 2Emory Vaccine Center, Yerkes National Primate Center, Atlanta, GA, United States, 3Department of Pathology, Emory University School of Medicine, Atlanta, GA, United States

315  Decreased Diversity of Gut Microbiota Is Associated With Immune Status During HIV-1 Infection
Piotr Nowak1, Babilonia Bargasho2, Ekatarina Avershina3, Kajsa Noya1, Jan Vesterbacka1, Marius Trossell1, Knut Rudi1, Anders Sönnerborg1
1Department of Infectious Diseases, Karolinska Institute, Huddinge, Sweden, 2Department of Laboratory Medicine, Karolinska Institute, Huddinge, Sweden, 3Department of Chemistry, Biotechnology and Food Science, Norwegian University of Life Sciences, Ås, Norway, 4Infectious Diseases, Oslo University Hospital, Oslo, Norway

316  Dysregulated miR-34a-SIRT1-Acetyl-p65 Axis Induces Immune Activation in Chronic SIV Infection
Mahesh Mohan1, Andrew Alan Lackner2, Xavier Alvarez Comparative Pathology, Tulane National Primate Research Center, Covington, LA, United States

317  Dysbiotic Bacteria Translocate in Progressive SIV Infection
Zachary Klaes1, Elias Schwartzman1, Alexandre Ortiz2, Lauren Canary1, Marlam Quinones2, Jason Brenchley1
1Laboratory of Molecular Microbiology, NIAID/NIH, Bethesda, MD, United States, 2NIAID/NIH, Bethesda, MD, United States
Session P-D2 Poster Session

Wednesday March 5, 2014, 2:30 PM–4:00 PM  Exhibit Hall A

New SIV Models

318.LB Viral Suppression Was Induced by Anti-PD-1 Following ARV-Interruption in SIV-Infected Mice

Stephen W. Mason1, Srisowmya Sanisetti1, Christa Osuna-Gutierrez2, So-Yan Lim3, Susan Chanelewski4, Shalyn Campbell5, Daniel Tenney5, Scott Balsis6, James B. Whitney7

1Discovery Virology, Bristol-Myers Squibb, Wallingford, CT, United States, 2Center for Virology and Vaccine Research, Bristol-Myers Squibb, Boston, MA, United States, 3Center for Virology and Vaccine Research, Beth Israel Deacons Medical Center, Harvard Medical School, Boston, MA, United States

319 A Novel HIV-1mt Encoding CCR5-Tropic Env Established Persistent Infection in Cynomolgus Macaques

Akatsuki Saito1, 2, Kazuhiro Matsuoka1, 2, Hirotaka Oda1, 2, Hiroyuki Otsuki4, Takeshi Yoshida5, Yasumasa Iwataki6, Wataru Sugita7, Tetsuro Matano8, Tomoyuki Miura4, Hirofumi Akari9

1Center for Human Evolution Modeling Research, Primate Research Institute, Kyoto University, Inuyama, Japan, 2Japan Foundation for AIDS Prevention, Chiyoda-ku, Japan, 3Clinical Research Center, National Nagoya Medical Center, Nagoya, Japan, 4Laboratory of Primate Model, Institute for Virus Research, Kyoto University, Kyoto, Japan, 5AIDS Research Center, National Institute of Infectious Diseases, Shinjuku-ku, Japan, 6Department of Medicine, University of Pittsburgh, Pittsburgh, PA, United States, 7Immunology, University of Pittsburgh, Pittsburgh, PA, United States, 8Division of Infectious Diseases, Shinjuku-ku, Japan

Session P-D3 Poster Session

Wednesday March 5, 2014, 2:30 PM–4:00 PM  Exhibit Hall A

SCID Mice

321 Immune-Pathogenesis/-Therapy of Persistent HIV-1 Infection in Humanized Mice

Lishan Su

Microbiology and Immunology, UNC-Chapel Hill, Chapel Hill, NC, United States

322 Dual Roles of Plasmaacytoid Dendritic Cells in HIV-1 Infection and Pathogenesis

Guangming Li1, Menglan Cheng2, Jun-ichi Nunoya3, Liang Cheng3, Haitao Guo1, Haisheng Yu1, Yong-jun Liu1, Lige Zhang4, Lishan Su5

1University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 2Institute of Biophysics, Chinese Academy of Sciences, Beijing, China, 3Baylor Research Institute, Dallas, TX, United States

323 Characterizing the Acute Spread of Cell-Associated HIV in Humanized Mice

Kenneth M. Law1, Alice W. Yewdall2, Benjamin K. Chen2

Infectious Disease, Icahn School of Medicine at Mount Sinai, New York, NY, United States

Session P-D4 Poster Session

Wednesday March 5, 2014, 2:30 PM–4:00 PM  Exhibit Hall A

Non-Pathogenic vs Pathogenic Hosts

324 Differential TCR Activation and TRAIL Regulation in Sooty Mangabeys and Rhesus Macaques

Shan Yu1, Kenneth Rogers2, Francois Villinger2, Amitinder Kaur2

1Division of Immunology, Harvard Medical School, Southborough, MA, United States, 2Division of Pathology, Emory University, Atlanta, GA, United States, 3Harvard Medical School, Southborough, MA, United States

325 Divergent CD4+ T Memory Stem Cell Dynamics in Pathogenic and Nonpathogenic SIV Infections

Emily K. Cartwright1, Colleen McGary2, Barbara Cervasio3, Benton Lawson4, Steven E. Boosinger5, Thomas H. Vanderford6, Mirko Paldanini7, Ann M. Chahroudi8, Guido Silvestri9

1Yerkes National Primate Research Center, Emory Vaccine Center, Atlanta, GA, United States, 2Department of Pediatrics, Emory University, Atlanta, GA, United States

326 Double-Negative T Cells Are Functionally Distinct and Maintained in SIV-Infected Sooty Mangabeys

Namita Rout1, James M. Billingsley2, Shan Yu3, Alexandra Gryzynia2, Premela A. Rajakumar1, Arnaud Colantonio1, Robert P. Johnson1, Jim Else1, Amntinder Kaur9

1Immunology, NEPRC-HMS, Southborough, MA, United States, 2Wellesley College, Wellesley, MA, United States, 3Animal Resources, Yerkes National Primate Research Center, Atlanta, GA, United States

Session P-D5 Poster Session

Thursday March 6, 2014, 2:30 PM–4:00 PM  Exhibit Hall A

Compartmentalization

329 Transient Compartmentalization of SIV Variants in the Breast Milk of African Green Monkeys

Carrie Ho

Human Vaccine Institute, Duke University Medical Center, Durham, NC, United States

330 HIV Migrates Bi-Directionally Between Blood and Cerebrospinal Fluid and Between Blood and Semen

Antoine Chaillon1, 2, Sara Gianella1, Joel O. Wertheim3, Sergei L. K. Pond4, Douglas D. Richman1, 2, Sanjay R. Mehta1, 3, David M. Smith1, 3

1Pathology, University of California San Diego, La Jolla, CA, United States, 2INSERM UMR U966, Tours, France, 3Centre for Vaccine Research, University of Pittsburgh, Pittsburgh, PA, United States, 4Microbiology and Molecular Genetics, University of Pittsburgh, Pittsburgh, PA, United States, 5Infectious Diseases and Microbiology, University of Pittsburgh, Pittsburgh, PA, United States

331 Poll Versus Env Genetics in SHIV-Infected Macaques Highlights Importance of Phylogenetic Signal

Chad Coomer1, Elizabeth M. Anderson1, Luke Smith1, Wei Shao1, Jonathan Spindler1, John W. Mellors2, John M. Coffin3, Mary F. Kearney4

1National Cancer Institute, NIH, Frederick, MD, United States, 2Division of Infectious Disease, Department of Medicine, University of Pittsburgh, Pittsburgh, PA, United States, 3Department of Molecular Biology and Microbiology, Tufts University, Boston, MA, United States, 4Division of Infectious Diseases, Department of Medicine, University of Pittsburgh, Pittsburgh, PA, United States
Session P-D6 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM Exhibit Hall A
New Themes in Host Control

333 Low Social Rank Prior To SIV or SHIV Infection Associates With Higher Viral Load in Chronic Infection
Gretchen N. Neigh1, Timothy Hayes1,2, Ronald Trumble1,3, Thomas H. Vanderford1,4, Diane G. Campanelli5, Constance S. Harrell1, Kirk Easley4, Mirko Piaardini3, Guido Silvestri1,3
1Pathology, Emory University, Atlanta, GA, United States, 2Yerkes National Primate Research Center, Atlanta, GA, United States, 3Emory University, Atlanta, GA, United States, 4Biostatistics, Emory University, Atlanta, GA, United States

334 Modulation of Natural Killer Cell Activity by Simian Immunodeficiency Virus Peptides
Jamie L. Schaefer1, Natasha Guha2, Nancy A. Wilson1, David T. Evans2
1Harvard University, Southborough, MA, United States, 2University of Wisconsin, Madison, WI, United States

Session P-E1 Poster Session
Tuesday March 4, 2014, 2:30 PM–4:00 PM Exhibit Hall A
Modulating Immune Activation

335 Rosuvastatin Reduces Immune Activation and Inflammation in Treated HIV Infection
Nicholas Funderburg1, Brian Ciagetti1, Ying Jiang1, Sara M. Debanne1, Norma Storer1, Danielle Labbato1, Steven Juchnowski1, Brian Ferranti2, Michael Lederman3, Grace A. McComsey2
1Health and Rehabilitation Sciences, The Ohio State University, Columbus, OH, United States, 2Case Western Reserve University/Case Medical Center, Cleveland, OH, United States, 3Epidemiology and Biostatistics, Case Western Reserve University, Cleveland, OH, United States, 4University Hospitals Case Medical Center, Cleveland, OH, United States

336 Effects of Prednisolone On CD4 Counts and HIV Disease Progression: A Two-Year Clinical Trial
Christa Kasang1, Samuel Kalluya1, Charles Majinge2, Gilbert Kongola2, Mathias Milewa2, Irene Massawe2, R Kayemera, K Magambo, H Klinker, E Lederman1, W Preiser, D Hofmann, J Hain, A Müller, Weissbrich, Albrecht Ulmer2, Axel Rethwilm1, August Stich1, Carsten Scheller1
1Institute of Virology and Immunobiology, Bugando Medical Centre, Mwanza, United Republic of Tanzania, 2Bugando Medical Centre, Mwanza, United Republic of Tanzania

337 Sevelamer Does Not Decrease Plasma LPS or sCD14 But Does Decrease Soluble Tissue Factor and LDL
Netanya G. Sandler1, Xinyan Zhang2, Ronald J. Bosch3, Nicholas T. Funderburg1, Janet K. Robinson1, Daniel C. Douket1, Cara C. Wilson3, Steven G. Deeks1, Michael M. Lederman3, Rajesh T. Gandhi3, for the AS296 Study Team
1Internal Medicine, University of Texas Medical Branch at Galveston, Galveston, TX, United States, 2Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, United States, 3Case Western Reserve University, Cleveland, OH, United States, 4NIHAIL Vaccine Research Center, National Institutes of Health, Bethesda, MD, United States, 5Internal Medicine, University of Colorado, Aurora, CO, United States, 6San Francisco General Hospital, San Francisco, CA, United States, 7Massachusetts General Hospital and Ragon Institute, Boston, MA, United States

338 Reduction of sCD163, SP and PD1+ Th Cell Levels in a Phase 1B Trial of the NK1R Antagonist Aprepitant
Pablo Tebas1, Serguei Spitsin1, Jeffrey Barrett1, Florin Tuluc1, Okan Elci2, James Koretz1, Wayne Wagner1, Deborah Kim1, Renae Catalano1, Steven D. Douglas2
1University of Pennsylvania, Philadelphia, PA, United States, 2Children’s Hospital of Philadelphia Research Institute, Philadelphia, PA, United States, 3Westat, Rockville, MD, United States

339 Rifaximin Has Marginal Impact On Immune Activation in Immune Non-Responders To ART – ACTG 5286
Allan R. Tenorio1, Cara C. Wilson2, Ellen S. Chan1, Ronald J. Bosch3, Bernard J. Macatangay1, Suria Yesmin1, Sarah W. Read4, David M. Margolis4, Jeffrey M. Jacobson5, Alan L. Landay1
1Medicine, Rush University Medical Center, Chicago, IL, United States, 2Medicine, University of Colorado Health Sciences Center, Aurora, CO, United States, 3Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, United States, 4Center for Biostatistics in AIDS, Harvard School of Public Health, Boston, MA, United States, 5Medicine, University of Pittsburgh, Pittsburgh, PA, United States, 6Frontier Sciences, Amherst, NY, United States, 7Division of AIDS, National Institutes of Health, Bethesda, MD, United States, 8Medicine, University of North Carolina, Chapel Hill, NC, United States, 9Medicine, Drexel University, Philadelphia, PA, United States, 10Immunology and Microbiology, Rush University Medical Center, Chicago, IL, United States

340 Reduced Immune Activation During Tenofovir-Emtricitabine Therapy in HIV-Negative Individuals
Jose R. Castillo-Mancilla1, Annie Merid1, Sharon Selfert2, Jia-Hua Zheng3, Becky J. Kerr4, Edward M. Gardner5, Brent E. Palmer6, Lane Bushmann7, Samantha Malwinney8, Peter L. Anderson8
1Infectious Diseases, University of Colorado, Aurora, CO, United States, 2Pharmaceutical Sciences, University of Colorado, Aurora, CO, United States, 3Infectious Diseases, Denver Health Hospital, Denver, CO, United States, 4Allergy and Immunology, University of Colorado, Aurora, CO, United States, 5Biostatistics and Informatics, University of Colorado, Aurora, CO, United States

341 Mesalamine To Reduce Immune Activation During HIV Infection: A Randomized Controlled Trial
Ma Somsook1, Richard M. Dunham2, Michelle Cohen3, Rebecca Albright1, Teri Liegler1, Yuanner Wu2, Jeffrey N. Marlin3, Priscilla Y. Hsue4, Steven G. Deeks5, Joseph M. McCune5, Peter W. Hunt6
1University of California San Francisco, San Francisco, CA, United States

342 Decreased Levels of D-Dimer After Probiotic Supplementation in Patients Receiving ART
Birgitte Stiksrud1, Piotr Nowak2, Dag Kval1, Anders Thalme2, Birgitte Stiksrud1, Piotr Nowak2, Dag Kval1, Anders Thalme2, Marius Trosi1
1Oslo University Hospital, Oslo, Norway, 2Karolinska University Hospital, Stockholm, Sweden, 3TINE SA, Oslo, Norway

Session P-E2 Poster Session
Tuesday March 4, 2014, 2:30 PM–4:00 PM Exhibit Hall A
Therapeutic Vaccines and Immunotherapies

343 Immune Function and Viral Load Post AGS-004 Administration To Chronic HIV Subjects Undergoing STI
Mark DeBenedette1, Irina Tcherepanova1, Alicia Gamble1, Joe Horatinovich2, Jason Harris2, Jean-Pierre Routy2, Charles Nicolette2, AGS-004-001 Study Team
1Immunology, Argos Therapeutics, Inc, Durham, NC, United States, 2McGill University Health Centre, Montreal, QC, Canada

344 Immunogenicity of AGS-004 Dendritic Cell Therapy in Patients Treated During Acute HIV Infection
Cynthia L. Gay1, Narcie Archim2, Irina Tcherepanova1, Esther Villardi1, Charles Hicks1, Mary Kearney1, John Coffin3, Mark DeBenedette4, Joseph Eron5, Charles Nicolette2, David M. Margolis7
1Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 2Research and Development, Argos Therapeutics, Inc, Durham, NC, United States, 3Infectious Diseases, Denver Health Hospital, Denver, CO, United States, 4Argos Therapeutics, Inc, Durham, NC, United States, 5Medicine, Duke University, Durham, NC, United States, 6Translational Research Unit, National Cancer Institute, Frederick, MD, United States, 7National Cancer Institute, Frederick, MD, United States

345 Immunogenicity and VL Rebound After ATI in Chronic HIV Infected Patients Receiving MVA-B
Beatriz Mothe1, Miriam Rosas1, Montserrat Plana2, Núria Climent1, Jose Luis Jimenez1, Judith Pich1, Mariano Esteban3, Felipe Garcia1, Christian Brande1
1Instituto de Investigación en Cáncer, Barcelona, Spain, 2Hospital Clinic-HIVACAT, Badalona, Spain, 3Hospital Clinic-HIVACAT, IDIBAPS, University of Barcelona, Badalona, Spain, 4Hospital Gregorio Marañón, Madrid, Spain, 5Centro Nacional de Biotecnología, Madrid, Spain, 6Hospital Clinic-HIVACAT, IDIBAPS, University of Barcelona, Barcelona, Spain

346 Dynamics of VL Rebound After cART Interruption in HIV Patients Receiving MVA-B plus Disulfiram
Beatriz Mothe1, Sonsoles Sanchez-Palomino2, Jose Luis Jimenez1, Jose M. Gatell3, Bonaventura Clotet1, Mariano Esteban4, Montserrat Plana2, Juan Carlos Lopez Bernaldo de Quirós3, Christian Brande1, Felipe Garcia2
347 Vaccination With Autologous Dendritic Cells Pulsed With Autologous HIV-Infected Apoptotic Cells
Bernard J. Macatangay1, Sharon A. Riddell1, Nicole D. Wheeler1, Mary J. Buff1, Aarika Yates1, Luann Borowski1, Theresa L. Whiteside1, Charles R. Rinaldo2
1Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, 2Yale University School of Medicine, New Haven, CT, United States

348 Systems Biology, HIV Disease, and RNAs Big and Small
Michael Katze
University of Washington, Seattle, WA, United States

349 CoRSeq2–3: Novel Coreceptor Usage Prediction Algorithms for HIV-1 Subtypes B, C, D and CRF01_AE
Kieran Cashin1, Lachlan R. Gray1, Katherine Harvey2, Danielle Perez-Bercoff1, Guinvere Q. Lee1, Jasminika Steljeskov1, Michael Roche1, P. Richard Harrigan1, Melissa J. Churchill1, Paul R. Gorry2
1Center for Biomedical Research, Burnet Institute, Melbourne, Australia, 2Department of Microbiology and Immunology, University of Melbourne, Melbourne, Australia, 3Department of Biochemistry and Molecular Biology, Monash University, Melbourne, Australia, 4Center Recherche Public de la Santé, Luxembourg, Luxembourg, 5BC Center for Excellence in HIV/AIDS, University of British Columbia, Vancouver, BC, Canada

350 Identification of Novel B*57:01 Restricted Peptides From HIV gp140 Using Immunopeptidomics
Sri H. Ramaratnam1, Nadine L. Dudek2, Robert J. Center3, Damien F. J. Purcell1, Anthony W. Purcell1
1Department of Biochemistry and Molecular Biology, Monash University, Clayton, Australia, 2Department of Microbiology and Immunology, University of Melbourne, Parkville, Australia

351 New Summaries and Computational Tools at Los Alamos HIV Immunology Database
Karina Yusim1, Shihai Feng2, Hyejin Yoon3, KumKum Ganguly1, Jennifer Mackie1, James Zsinger4, Anthony P. West5, Pamela Bjorkman1, Brian Foley6, Bette T. Korber1
1HIV Database, T-6, Los Alamos National Laboratory, Los Alamos, NM, United States, 2California Institute of Technology, Pasadena, CA, United States

352 Identification of Pattern Recognition Receptor for HIV-1 in Human Dendritic Cells
Sunnie M. Yoh1, Monika Schneider2, Stephen Soonthornvacharin2, Kevin Olivieri2, Sourav Bandopadhyay2, Elisa Decastros1, Adolfo G. Sastre2, Sumit K. Chanda1
1Inflammatory Diseases, Sanford Burnham Medical Institute, La Jolla, CA, United States, 2Helen Diller Family Comprehensive Cancer Center, University of California San Francisco, San Francisco, CA, United States

353 Plasmacytoid Dendritic Cell Phagocytosis of IgG Anti-p24 Associates With Control of HIV Infection
Christian Tjani1, James Taylor1, Mazmah A. Morshidi1, Jeffrey N. Martin2, Steven G. Deeks2, Dino Tan1, Silvia Lee1, Sonia Fernandez1, Martyn A. French1
1School of Pathology and Laboratory Medicine, University of Western Australia, Perth, Australia, 2School of Medicine, University California San Francisco, San Francisco, CA, United States, 3Lung Institute of Western Australia, University of Western Australia, Perth, Australia

354 Recruitment of Functionally Different NK Cells To the Rectal Mucosa in Vaccinated Macaques
Namal P. M. Liyanage1, Shari N. Gordon1, Monica Vaccari1, Poonam Pegg1, Melvin Doster2, David Venzon3, James Tartaglia3, Susan W. Barnett4, Nelson Michael5, Genoveffa Franchini6,7
1National Cancer Institute, National Institutes of Health, Bethesda, MD, United States, 2Department of Research and Development, Sanofi Pasteur, Swiftwater, PA, United States, 343 Sydney Street, Novartis Vaccines & Diagnostics, Cambridge, MA, United States, 4U.S. Military HIV Research Program, Rockville, MD, United States

355 HIV Myeloid-Derived Suppressor Cells Inhibit the Protective Response To Cytomegalovirus
Ankita Garg1, Stephen A. Spector2,3
1Pediatrics, University of California San Diego, La Jolla, CA, United States, 2Rady Children’s Hospital, San Diego, CA, United States
Antibody Responses in Anogenital Secretions of RV305, a Late Prasert Thongcharoen3, Punnee Pitisuttithum4, Michael Eller5, Silvia Ratto-Gardasil® in HIV-Infected Adults: An RCT Bangkok Noi, Thailand, 4Clinical Tropical Medicine, Mahidol University, Nakhon Thailand, 3Department of Microbiology, Siriraj Hospital, Mahidol University, Bangkok, Thailand, 2Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, 2Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, 2Pathology, New York University Medical Center, New York, NY, United States, 2Epidemiology, The Johns Hopkins University, Baltimore, MD, United States, 6Medicine, Division of Infectious Disease, Georgetown University Medical Center, Washington, DC, United States, 6Human Retrovirus Pathogenesis Section, NCI, National Institutes of Health, Bethesda, MD, United States, 6Human Retrovirus Pathogenesis Section, NCI, National Institutes of Health, Bethesda, MD, United States, 6Medicine, Division of Infectious Disease, Georgetown University Medical Center, Washington, DC, United States, 6Pathology, SUNY Downstate Medical Center, Brooklyn, NY, United States, 5Medicine, University of Southern California, Los Angeles, CA, United States, 5Medicine, Division of Infectious Disease, Georgetown University Medical Center, Washington, DC, United States, 5Pathology, SUNY Downstate Medical Center, Brooklyn, NY, United States, 4Biostatistics and Data Management Section, NCI, National Institutes of Health, Bethesda, MD, United States, 4Department of Biochemistry and Molecular Biology, University of Maryland School of Medicine, Baltimore, MD, United States, 4Department of Microbiology and Immunology, University of Maryland School of Medicine, Baltimore, MD, United States, 4Department of Pediatrics, Tulane University Medical Center, New Orleans, LA, United States, 4Service d’Ingénierie Moléculaire des Protéines, CEA, Gif-sur-Yvette, France, 4Department of Medicine, University of Maryland School of Medicine, Baltimore, MD, United States

Complex Impact of Reversion Mutations and CD8+ T Cell Escape Mutations On HIV-1 Fitness Hongshuo Song1, Tammy Bhattacharya2, Nilu Goonetilleke3, Kevin Wiehe4, Andrew McMichael4, George Shaw4, Beatrice Hahn5, Alan Perelson6, Barton Haynes7, Feng Gao1
1Duke Human Vaccine Institute, Duke University Medical Center, Durham, NC, United States, 2Los Alamos National Laboratory, Los Alamos, NM, United States, 3Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom, 4Department of Microbiology, University of Pennsylvania, Philadelphia, PA, United States

Characterizing Acute HIV-1B CTL Escape by Full-Genome “Deep” Sequencing Christian L. Boutwell, Damien Tully, Rebecca Batorsky, Karen Power, Aaron Seese, Michael Sirignano, Marcus Altfeld, Todd M. Allen
Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States

HIV-1 gp120-Specific Antibody Dependent Cell-Mediated Cytotoxicity in HIV-1 Elite Controllers Mariana M. Mata1, Fareeha Mahmood1, Elizabeth T. Golub2, Ruth M. Greenblatt3, Kathryn Anastos4, Marek Nowicki5, Mary Young6, Helen Durkin7, Seema N. Dessi8, Linda L. Baum9
1Immunology/Microbiology, Rush University Medical Center, Chicago, IL, United States, 2Epidemiology, The Johns Hopkins University, Baltimore, MD, United States, 3Clinical Pharmacy, Medicine, Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA, United States, 4Medicine, Epidemiology and Population Health, Montefiore Medical Center, Bronx, NY, United States, 5Medicine, University of Southern California, Los Angeles, CA, United States, 6Medicine, Division of Infectious Disease, Georgetown University Medical Center, Washington, DC, United States, 7Pathology, SUNY Downstate Medical Center, Brooklyn, NY, United States

The Specificity of V3 Antibodies in RV144 Plasma Implicated in Reducing HIV Infection Susan Zolla-Pazner1, Constance Williams2, Morgane Rolland3, Paul Edelfson4, Xiang-Peng Kong5, Arthur Nadas6, S. Tovanabutra7, Supachai Rekers-Ngam8, Martin Tolstrup9, Lars Østergaard10, Ole S. Segard11
1Department of Infectious Diseases, Aarhus University Hospital, Aarhus, Denmark, 2Research Program Infection and Cancer, German Cancer Research Center, Heidelberg, Germany, 3Chemical Biology Core Facility, European Molecular Biology Laboratory, Heidelberg, Germany, 4Department of Pathology, Copenhagen University Hospital, Hvidovre, Denmark

CD8 T Cell Responses Emerging During Acute HIV Infection Drive Long-Term Control Hendrik Streack1, Jean-Pierre Routy2, Helko Jussen3, Anthony Kelleher2, Frederick Hecht3, Rafick-Pierre Sekaly2, Eric Rosenberg4, Todd Allen5, Ali Carrington6, Marcus Altfeld7
1US Military HIV Research Program, Silver Spring, MD, United States, 2Chronic Viral Illness Service, McGill University Health Centre, Montreal, QC, Canada, 3Practice Jessen + Jessen, Berlin, Germany, 4Centre for Immunology, St. Vincent’s Hospital, Darlinghurst, Australia, 5School of Medicine, University of New South Wales, Sydney, Australia, 7Pathology, SUNY Downstate Medical Center, Brooklyn, NY, United States

HIV Cell Tropism Dependent Impact of CTL Escape Mutations in Gag On Viral Replicative Capacity Benedikt Grandel, Sara Wennigl, Franziska Winter, Sven Bretschneider, Bernd Salzberger, Arne Schneidewind
1Internal Medicine I, University of Regensburg, Regensburg, Germany, 2Internal Medicine, University of Bonn, Bonn, Germany

Session P-E7 Poster Session Thursday March 6, 2014, 2:30 PM–4:00 PM Exhibit Hall Immune Response To Infection
375LB Modification of Antibody 10E8 To Improve HIV-1 Neutralization
Gilad Oefk1, Gabriel Lu1, Baoshan Zhang1, Amy Bao2, Yongqing Yang1, McKee Krishna1, Brett Zirkle1, Jinghe Huang1, Mark Connors1, John R. Mascola1, Peter D. Kwong2
1Vaccine Research Center, National Institutes of Health, Bethesda, MD, United States, 2Laboratory of Immunoregulation, National Institutes of Health, Bethesda, MD, United States

376 Association of Gag-Specific CD8+CD95+ CD8+ T-Cell Responses in Lymph Nodes With Lower Viral Loads
Hiroshi Ishii1, Saori Matsuoka1, Tetsuro Matano2
1AIDS Research Center, National Institute of Infectious Diseases, Tokyo, Japan, 2The Institute of Medical Science, The University of Tokyo, Tokyo, Japan

377 Distinct Functional Properties of HIV-Specific Cytotoxic CD4 T Cells Compared To Th1 or CD8 T Cells
Susan Johnson1, Richard Lu1, Alexander Oster1, Franco Pissani1, Mary A. Marovich1, Diane L. Bolton1, Hendrik Streck1
1US Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States, 2Division of AIDS, NIH/HIVAD, Bethesda, MD, United States

378 CD8+ T Cells From HLA-B*57 Elite Suppressor Inhibit Replication of HIV-1 Escape Mutants
Christopher W. Pohmeyer1, Robert W. Buckheit2, 3, Robert F. Siliciano4, 5, Joel N. Blankson1
1School of Medicine, The Johns Hopkins Medical Institution, Baltimore, MD, United States, 2National Cancer Institute, NIH, Frederick, MD, United States, 3The Johns Hopkins Medical Institution, Baltimore, MD, United States, 4Howard Hughes Medical Institute, Baltimore, MD, United States

Session P-F1 Poster Session
Tuesday March 4, 2014, 2:30 pm–4:00 pm

Mechanisms of HIV Latency

379LB The Tat Inhibitor, Cortistatin A, Suppresses Transcription and Reactivation of HIV Latent Cells
Guillaume Mousseau1, Remi Fromentin1, Nicolas Chomont2, Susana T. Valente1
1The Scripps Research Institute, Jupiter, FL, United States, 2Vaccine and Gene Therapy Institute, Port Saint Lucie, FL, United States

380 Mechanisms by Which Negative Elongation Factor (NELF) Establishes and Maintains HIV Latency
Gillian M. Schiralli Lester1, Malini Natarajan2, Andrew J. Henderson1
1Medicine, Infectious Disease, Boston University Medical Center, Boston, MA, United States, 2Stowers Institute for Medical Research, Kansas City, MO, United States

381 Differential Role of Bromodomain Proteins in HIV-1 Latency
Daniela Boehm1, Pao-Chen Li2, Hendrik Sy1, Melanie Ott1
Gladstone Institute of Virology and Immunology, Gladstone Institute/University of California San Francisco, San Francisco, CA, United States

382 The NCO2R2-Nurr1-CoREST Axis Impairs HIV Reactivation in Latently Infected Microglial Cells
David Alvarez, Blowjat Das, Yoelvis Garcia-Mesa, Curtis Dobrowolski, Jonathan Kari
Molecular Biology and Microbiology, Case Western Reserve University, Cleveland, OH, United States

383 Repression of HIV Transcription in Memory CD4+ T Cells by Blimp-1
Katarzyna Kaczmarek1, Malini Natarajan1, Zelda Euler1, Galit Alter2, Andrew J. Henderson1
1Molecular and Translational Medicine, Boston University School of Medicine, Boston, MA, United States, 2Stowers Institute for Medical Research, Kansas City, MO, United States, 3Ragon Institute of MGH, MIT and Harvard, Boston, MA, United States

384 HIV-1 Reactivation and Autophagy Inhibition Synergize To Cell Death via Amino Acid Deprivation
Metodi V. Stankov1, Diana Panayotova-Dimitrova2, GeorG M. N. Behrens3
1Department for Clinical Immunology and Rheumatology, Hannover Medical School, Hannover, Germany, 2Department of Dermatology, Venereology and Allergology, Mannheim Clinic of University of Heidelberg, Mannheim, Germany

385 JAK Inhibitors Tofacitinib and Ruxolitinib Block T-Cell Activation Mediated HIV Replication
Franck P. Dupuy2, Jessica Brett1, Christina Gavegnano3, 4, Raymond F. Schinazi1, 5, RafiK P. Sekaly6
1Vaccine and Gene Therapy Institute VGTI-FL, Port Saint Lucie, FL, United States, 2Division of Pediatrics, Center for AIDS Research, Laboratory of Biochemical Pharmacology, Atlanta, GA, United States, 3Veterans Affairs Medical Center, Decatur, GA, United States

386LB Human genome shRNA Screen Identifies Cellular Factors Controlling Latency
Shweta Hakre1, Martin Kampmann2, Nina N. Hosmanc3, Michael C. Bassik4, Erik Verschurem5, Emilie Battllivid6, Robert F. Siliciano7, Nevan J. Krogan8, Jonathan S. Weissman1, Eric Verdin9
1Virology and Immunology, Department of Medicine, UCSD, Glasmadence, UCSD, San Francisco, CA, United States, 2Cellular and Molecular Pharmacology, Howard Hughes Medical Institute, University of California, San Francisco, CA, United States, 3Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, United States, 4Genetics, Stanford University School of Medicine, Stanford, CA, United States, 5Cellular and Molecular Pharmacology, University of California, San Francisco, CA, United States, 6Virology and Immunology, Glasmadence, UCSD, San Francisco, CA, United States, 7Medicine, Howard Hughes Medical Institute, Johns Hopkins School of Medicine, Baltimore, MD, United States, 8Virology and Immunology, Cellular and Molecular Pharmacology, UCSD, Glasmadence, UCSD, San Francisco, CA, United States, 9Virology and Immunology, Department of Medicine UCSD, Glasmadence, UCSD, San Francisco, CA, United States

Session P-F2 Poster Session
Tuesday March 4, 2014, 2:30 pm–4:00 pm

Dynamics of Persistent and Rebound HIV

387 Incomplete Adherence To CART Is Associated With Higher Levels of Residual HIV-1 Viremia
Jonathan Z. Li1, Sebastien Gallier2, Heather Ribaudo3, Andrea Heisey1, David R. Bangsberg1, Daniel R. Kuritzkes1
1Brigham and Women’s Hospital, Harvard Medical School, Boston, MA, United States, 2Hopital Saint Louis, Paris, France, 3Harvard School of Public Health, Boston, MA, United States

388 Viral Dynamics of HIV-1 Rebound Viremia
Benjamin Scheineld, Katharine J. Bar
Medicine, University of Pennsylvania, Philadelphia, PA, United States

389 Transcripts Associated With The HIV Reservoir Correlate With The Pool Size of Long-Lived CD4 T Cells
Maria J. Buzon1, 2, Qiang Gu1, David N. Straus1, Hong Sun1, Forencia Pareyna3, 4, Nadine Zangger2, Xu Yu2, Amaio Tolenti5, Eric S. Rosenberg6, Mathias Lichterfeld7
1Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States, 2Infectious Disease Division, Massachusetts General Hospital, Boston, MA, United States, 3AIDS Research Center, The First Affiliated Hospital of China Medical University, Shenyang, China, 4Infectious Disease Division, Brigham and Women’s Hospital, Boston, MA, United States, 5Institute of Microbiology, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland

390 Massive Expansion of HIV Infected Cells With Identical Proviruses in Patients On Suppressive ART
Mary Kearney1, Luke Smith1, Johnathan Spindler1, Charles Coomer1, Guillaume J. Besson2, Elizabeth M. Anderson1, Wei Shao3, John M. Coffin4, John W. Mellors5, 6, Frank Maldarelli7, 8
1National Cancer Institute, NIH, Frederick, MD, United States, 2University of Pittsburgh, Pittsburgh, PA, United States, 3Advanced Biomedical Computing Center, SAV, Frederick, MD, United States, 4Department of Molecular Biology and Microbiology, Tufts University, Boston, MA, United States, 5Department of Medicine, University of Pittsburgh, Pittsburgh, PA, United States

CROI 2014
391 Effects of CCR5-Δ32 Heterozygosity On HIV-1 Reservoir Size and Immune Activation
Charlene Wang1, 2, Mohamed Abdel-Mohsen2, 3, Matthew C. Strain2, 4, Steven M. Lalley2, 3, Leslie Cockerham2, 3, Steven Yuki1, 2, Teri Liegler2, Douglas D. Richman2, 3, Steven G. Deeks2, 3, Salish K. Pillai1, 2, 3
1Emory University, Atlanta, GA, United States, 2Blood Systems Research Institute, San Francisco, CA, United States, 3University of California, San Francisco, CA, United States, 4University of California, Los Angeles, CA, United States, 5Veterans Affairs San Diego Healthcare System, San Diego, CA, United States, 6Veterans Affairs Medical Center, San Francisco, CA, United States

392 Seminal CMV Replication, Immune Activation, and Higher Proviral HIV DNA During Suppressive ART
Sara Gianella1, Marta Massanella1, Douglas D. Richman2, 3, Susan J. Little2, Colisa A. Spin1, 2, Eric S. Daar1, Michael P. Duber2, Richard H. Haubrich3, Sheldon R. Morris1, Davey M. Smith4, 5, and the CTG 592 Team
1Medicine, University of California San Diego, La Jolla, CA, United States, 2Veterans Affairs San Diego Healthcare System, San Diego, CA, United States, 3Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA, United States, 4University of Southern California Keck School of Medicine, Los Angeles, CA, United States, 5Veterans Affairs San Diego Healthcare, San Diego, CA, United States

393 Persistent HIV in Plasma During cART Can Lead To Rebound Viremia After Treatment Interruption
Junko Hattori1, Wei Sha2, Shawn Hill3, Francesco R. Simonetti1, Elizabeth M. Anderson1, Catherine A. Rehm1, Sara E. Jones1, Richard T. Davey2, Frank Maldarelli1
1HIV Drug Resistance Program, National Cancer Institute, Frederick, MD, United States, 2Advanced Biomedical Computing Center, SAIC-Frederick, Frederick National Laboratories for Cancer Research, Frederick, MD, United States, 3National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, 4Clinical Research Directorate/CMRP, SAIC-Frederick, Inc., Frederick National Laboratory for Cancer Research, Frederick, MD, United States

Session P-F4 Poster Session
Tuesday March 4, 2014, 2:30 pm–4:00 pm Exhibit Hall A

Effect of ART Early in HIV Infection
394 How To Characterize Post-Treatment Controllers in Patients Treated During Primary HIV Infection?
Eva Wolff1, Johannes Bogner1, Knud Schewe1, Veronique Avettand-Fenoël1, Christine Koepl2, Ramona Paul1, Jürgen Brust1, Albrecht Ulmer1, Lothar Schneider1, Hans Jaeger1, New Era Study Group
1MUC Research, Munich, Germany, 2Dept. of Infectious Diseases, University Munich, University Hospital, Munich, Germany, 3HÖD Study Center, Hamburg, Germany, 4Hôpital Necker - Enfants malades, Laboratoire de Virologie, Hôpital Necker, Enfants malades, Paris, France, 5Sorapis - Private practice Dr. Becker/Dr. Paul, Munich, Germany, 6Private practice Dr. Brust/Prof. Dr. Hensel/Dr. Ploeger/Dr.Schuster, Mannheim, Germany, 7Private practice Dr. Ulmer/Dr. Frietsch/Dr. Mueller, Stuttgart, Germany, 8Private practice Dr. Schneider, Freiburg, Germany, 9MNZ Kartspitz - HIV Research and Clinical Care Centre, Munich, Germany

395 Loss of HIV Serological Markers Following Early Treatment of Acute HIV Infection
Mark M. Manak1, Sheila Peet1, Jennifer Malia2, Ashley Shutt3, Srinivas Akaprat1, Tippawan Fankam1, James Fletcher1, Merlin Robb1, Jerome Kim1, Jintanat Ananworanich1
1US Military HIV Research Program, HIV, Silver Spring, MD, United States, 2US Military HIV Research Program, WRAIR, Silver Spring, MD, United States, 3Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, 4Thai Red Cross AIDS Research Center, Bangkok, Thailand

396 Early Antiretroviral Therapy Prevents the Establishment of HIV-1 Infection in Humanized-BLTL Mice
Qingsheng Li1, For Yue Tso1, Guobing Kang1, Wuxun Lu1, Yue Lin1, Wenjin Fan1, Chris J. Destache1, Charles Wood1
1Nebraska Center for Virology & School of Biological Sciences, University of Nebraska-Lincoln, Lincoln, NE, United States, 2Pharmacy Practice, Creighton University School of Pharmacy & Health Professions, Omaha, NE, United States

397LB Lack of Detectable HIV DNA in a PrEP Study Participant Treated During “Hyperacute” HIV Infection
Hiroyo Hatano1, Oliver Bacon1, 2, Stephanie Cohen1, 2, Albert Liu1, 2, Susan Buchbinder2, 1, Nicolas Chomont1, Mary Kearney1, Janet Siliciano2, Teri Liegler2, Steven G. Deeks2, 3
1Medicine, University of California, San Francisco, San Francisco, CA, United States, 2San Francisco Department of Public Health, San Francisco, CA, United States, 3Vaccine and Gene Therapy Institute of Florida, Port Saint Lucie, FL, United States, 4National Cancer Institute, Frederick, MD, United States, 5Johns Hopkins University, Baltimore, MD, United States

398 Early HAART in Primary HIV Infection Protects TCD4 Central Memory Cells and Can Induce HIV Remission
Antoine Chéret1, 2, Charline Bacchus1, Adeline Mélard1, Georges Nembot1, Catherine Blanc1, Assia Sami1, Véronique Avettand-Fenoël2, Asier Saaz-Corín1, Brigitte Autran1, Christine Rouzioux1, OPTIPRIM ANRS-147 Study Group
1EA 3620 Paris-Descartes University, Sorbonne Paris-Cité Virology Laboratory, Necker Enfants-Malades Hospital, Paris, France, 2Infectious Diseases Unit, Dron Hospital, Tourcoing, France, 3Pierre & Marie Curie University Paris VI, INSERM UMR-S 845 Immunology & Infection, Pitié-Salpêtrière Hospital, Paris, France, 4Epidemiology and Public Health Department, INSERM U1078, AP-HP Le Kremlin-Bicêtre, Paris, France, 5Unité de Régulation des Infections Rétrovirales, Institut Pasteur, Paris, France

Session P-F5 Poster Session
Wednesday March 5, 2014, 2:30 pm–4:00 pm Exhibit Hall A

Methods for Measuring Reservoirs
399LS A Scalable RNA RT-PCR Based Assay To Quantify Latency Disruption in HIV-1 Infected Cells
Jason M. Hataye1, Joseph P. Casazza2, David R. Ambrozak3, Eli Boritz3, Takuya Yamamoto4, Daniel C. Douek1, Richard A. Kouk5
1Vaccine Research Center, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

400 HIV Antibody Characterization To Quantify Reservoir Size Under Curative Interventions
Peter D. Burbelo1, Ahmad Bayat2, Craig S. Rhodes2, Rebecca Hoh3, Jeffrey N. Martin4, Gero Hüttler5, Joseph A. Kovacs3, Steven G. Deeks3, 1NIDCR, NIH, Bethesda, MD, United States, 2Dept. of Medicine, UCSF, San Francisco, CA, United States, 3Institute of Transfusion Medicine and Immunology, Heidelberg University, Mannheim, Germany, 4Critical Care Medicine Dept., Clinical Center, NIH, Bethesda, MD, United States

401 High-Throughput Analysis of Full-Length Proviral HIV-1 Genomes From PBMCs
Hiromi Imamichi1, Yan Guo2, Colin Ludka3, Ellen E. Paxonos4, H. Clifford Lane5, Da Wei Huang5, Richard A. Lempicki1, Michael P. S. Brown1
1NIAID, NIH, DHHS, Bethesda, MD, United States, 2Pacific Biosciences, Menlo Park, CA, United States, 3Leidos Biomedical Research, Inc., Frederick, MD, United States

402 Using Antibodies To Detect HIV Persistence in Treatment Intensification and Eradication Studies
Sheila M. Keating1, 2, Christopher D. Pilcher2, Gary Murphy3, Alex Welte2, Rashiha Kassanjee2, David Matten1, Mila Lebedeva1, Shelley N. Facente1, Steve G. Deeks3, Michael P. Bush1, 1Consortium for Evaluation of Performance of HIV Incidence Assays (CEPHIA), 2Blood Systems Research Institute, San Francisco, CA, United States, 3UCSF, San Francisco, CA, United States, 4Public Health England, London, United Kingdom, 5SACEMA, Stellenbosch, South Africa, 6Medicine, UCSF, San Francisco, CA, United States

403LB HIV DNA in PHI Associates With T Cell Immunity and Predicts Disease Progression and Rebound Viraemia
Jacob Hurst1, 3, James Williams1, Elisabeth Hamlyn1, Kersten Koetsch1, Sarah Fidler1, Abdel Babiker4, Jonathan Weber1, Tony Kelleher5, Rodney Phillips1, John Frater1, Spartus Trial Investigators
1University of Oxford, Oxford, United Kingdom, 2Imperial College, London, United Kingdom, 3University of New South Wales, Sydney, Australia, 4MRC Clinical Trials Unit, London, United Kingdom, 5University of New South Wales, Sydney, Australia
404 Next Generation Plasma HIV-1 RNA Single Copy Assays
Anthony R. Cillo1, David Vagman2, Margaret Bedson2, Elizabeth Anderson3, Mary Kearney1, Elizabeth Fyer1, Dianna Koontz2, John Coffin4, Michael Piatak2, John Mellors3
1School of Medicine, University of Pittsburgh, Pittsburgh, PA, United States, 2University of Pittsburgh, Pittsburgh, PA, United States, 3NCI-Frederick, Frederick, MD, United States, 4Tufts University, Boston, MA, United States

405 Assesment and Quantification of Cell Associate Unspliced HIV-1 RNA Using RT-ddPCR
Zixin Hu, Carlos Bercaril, Nina H. Lin, Jonathan Li, Andrea Helsey, Athie M. Talbris, Daniel R. Kurtzkes
Division of Infectious Diseases, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, United States

406 Measuring HIV Latency Over Time: Reservoir Stability and Assessing Interventions
Nancie M. Archin1, Amanda M. Crooks1, Rosalie Batson2, Anna B. Cope2, Noelle P. Dahl1, Joseph J. Eron3, Cynthia L. Gay1, JoAnn D. Kuruc1, David M. Margolis1,4, Ronald J. Bosch1
1Department of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 2Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 3Department of Microbiology & Immunology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 4Department of Biostatistics, Harvard School of Public Health, Boston, MA, United States

Session P-F5 Poster Session
Wednesday March 5, 2014, 2:30 pm–4:00 pm Exhibit Hall A
What and Where Is the Reservoir?

407LB The Role of HIV Integration Sites in Extensive Clonal Expansion of Infected Cells in Patients
Frank Maldarelli1, Xiaolin Wu1, Mary Kearney1, Ling Su2, Wei Shaoh1, Shawn Hill1, Francesco Simonetti1, Jon Spindler1, John Coffin1, Stephen H. Hughes1
1HIV Drug Resistance Program, NIH, Frederick, MD, United States, 2Leidos, Inc, Frederick, MD, United States, 3ISP/Advanced Biomedical Computing Center, Leidos, Inc., Frederick, MD, United States, 4Department of Molecular Biology and Microbiology, Tufts University School of Medicine, Boston, MA, United States

408 Identification of a New TH17 Subset That Contributes To HIV-1 Persistence in ART-Treated Subjects
Vanessa S. Wachech3,4, Annie Gosselin3, Patricia Monteiro3, Aurëlle Cleret-Buhot3,2, Sandrine DaFonseca3,4, Mohammad-Ali Jenabani1, Jean-Pierre Routy1, Petronela Ancuta3,2
1CR-CHUM, Montreal, QC, Canada, 2Université de Montréal, Montreal, QC, Canada, 3McGill University Health Centre, Montreal, QC, Canada

409 Identifying Defective and Identical Viral Genomes in HIV Reservoirs During Effective HIV Therapy
Susanne von Stockenstrom1, Lina Odevall1, Elizabeth Sinclair1, Rui A. Raposo3, Douglas F. Nixon1,4, Hiroyu Hattara3, Peter Hunt1, Peter Bacchetti1, Steven G. Deeks1, Frederic M. Hecht1, Sarah Palmer1,4
1Department of Microbiology, Tumor and Cell Biology, Karolinska Institute, Stockholm, Sweden, 2School of Medicine, University of California San Francisco, San Francisco, CA, United States, 3Division of Experimental Medicine, University of California San Francisco, San Francisco, CA, United States, 4Division of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA, United States, 5Centre for Virus Research, Westmead Millennium Institute for Medical Research and University of Sydney, Sydney, Australia

Session P-F6 Poster Session
Wednesday March 5, 2014, 2:30 pm–4:00 pm Exhibit Hall A
What Can We Learn From Bone Marrow Transplantation?

410 Healthy HIV-Infected Subjects Harbor HIV in Alveolar Macrophages, Which Can Impair Lung Function
Sushma K. Cribs1, David M. Guido1, Angela M. Caliendo1, Lou Ann Brown1, Jeffrey Lennarz2
1Pulmonary/Critical Care Medicine, Emory University, Atlanta, GA, United States, 2Brown University, Providence, RI, United States

411 Quantitative and Phylogenetic Analyses of Persistent HIV in Blood and GALT During Long-Term cART
Francesco R. Simonetti1, Shawn Hill1, Shao Wei2, Robert Gorlick1, Michael Piatak2, Mark Voellinger1, Stephen Wank1, Gabriella Diaz1, Joe Kovacs1, Frank Maldarelli1
1HIV Drug Resistance Program, National Cancer Institute, Frederick, MD, United States, 2Advanced Biomedical Computing Center SAIC-Frederick, Frederick, MD, United States, 3AIDS and Cancer Virus Program, Frederick National Laboratories for Cancer Research, Frederick, MD, United States, 4National Institute of Digestive and Kidney Diseases, Digestive Disease Branch, National Institutes of Health, Bethesda, MD, United States, 5National Institute of Health, Bethesda, MD, United States

412 The Immune Checkpoint Blockers PD-1, LAG-3 and TIGIT Are Associated With HIV Persistence During ART
Remi Fromentin1, Sandrina DaFonseca2, Wendy Bakeman1, Gabriela Khoury1, Elizabeth Sinclair1, Frederick Hecht1, Steven G. Deeks2, Sharon L. Lewin3,4, Raflick P. Sekaly1, Nicolas Chomont1
1VIGI Florida, Port St Lucie, FL, United States, 2Infectious Diseases, Alfred Hospital and Monash University, Melbourne, Australia, 3Medicine, UCSF, San Francisco, CA, United States, 4Centre for Biomedical Research, Bumet Institute, Melbourne, Australia

413 Distinct Patterns of TLR-Mediated HIV Reactivation in Latently-Infected Microglia vs Monocytes
David Alvarez, Yeolwi Garcia-Mesa, Biswajit Das, Curtis Dobrowolski, Stephanie Milne, Roxana Rojas, Jonathan Karn

414 CXCR3 and CCR5 Expression Are Associated With 2LTR Circles in Patients On Antiretroviral Therapy
Gabriela Khoury1, Jenny Anderson1,2, Remi Fromentin1, Nicolas Chomont1, Elizabeth Sinclair1, Wendy Hartogensis1, Peter Bacchetti1, Frederick M. Hecht1, Steven G. Deeks1, Sharon L. Lewin3
1Infectious Diseases, Monash University & Alfred Hospital, Melbourne, Victoria, Australia, 2Vaccine and Gene Therapy Institute of Florida, Port St Lucie, FL, United States, 3Medicine, University of California San Francisco, San Francisco, CA, United States, 4University of California San Francisco, San Francisco, CA, United States

415 CD4+ and CDB+ T Cell Activation Are Strongly Associated With HIV DNA IN Residual CD4+ T Cells
Leslie Cockerham1, Janet D. Siliciano1, Elizabeth Sinclair1, Uta O'Doherty1, Sarah Palmer1,4, Steven A. Yukl6, Matt C. Strain7, Robert F. Siliciano8, Douglas R. Richman1
1HIV/AIDS Division, University of California - San Francisco, San Francisco, CA, United States, 2Department of Medicine, Johns Hopkins University, Baltimore, MD, United States, 3Division of Experimental Medicine, University of California - San Francisco, San Francisco, CA, United States, 4Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, PA, United States, 5The University of Sydney, Sydney, Australia, 6San Francisco VA Medical Center, San Francisco, CA, United States, 7University of California - San Diego, San Diego, CA, United States, 8Johns Hopkins University, Baltimore, MD, United States

416 Targeting SIV Reservoirs via Autologous Hematopoietic Stem Cell Transplant in Rhesus Macaques
Maud Mavigner1, Benjamin Watkins2,3,4, Benton O. Lawson1, Ann Chahroudi2, Leslie S. Keen2,5, Guido Silvestri1
1Yerkes National Primate Research Center, Emory University, Atlanta, GA, United States, 2Department of Pediatrics, Emory University, Atlanta, GA, United States, 3Emory Transplant Center, Emory University, Atlanta, GA, United States, 4Department of Microbiology and Immunology, Case Western Reserve University, Cleveland, OH, United States

417 Dynamics of HSC Repopulation in Non-Human Primates Revealed by a Decade-Long Clonal Tracking
Sanggu Kim1, Namthim Kim1, Angela Presson1, Dong Sun An1, Robert E. Donahue1, Irvin S. Y. Chen1
1University of California, Los Angeles, Los Angeles, CA, United States, disc3. The Korea Bioinformatics Center, Daejeon, Republic of Korea, 2National Heart, Lung and Blood Institute, Bethesda, MD, United States
418 Impact of Systemic Cytotoxic Chemotherapy for Malignancies On HIV-1 Reservoir Persistence
Timothy J. Henrich1, Emily Hanhauser2, Jonathan Z. Li3, Andrea Heiley4, Jeremy S. Abrahamson3, Ayad Hamdani5, Philippe Armand6, Ann S. LaCasce7, Daniel R. Kuritzkes8
1Brigham and Women’s Hospital, Harvard Medical School, Cambridge, MA, United States, 2Bingham and Women’s Hospital, Cambridge, MA, United States, 3Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, 4Beth Israel Deacness Medical Center, Harvard Medical School, Boston, MA, United States, 5Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, United States

419 Modeling Functional Cure of HIV in Nonhuman Primates Using Gene–Modified Hematopoietic Stem Cells
Hans-Peter Kiem9, Christopher W. Peterson10, Patrick M. Younani11, Shi-Lok Hu12, Patricia Polacino13, Michael Holmes14, Philip Gregory15, Jianbin Wang16
1Transplantation Biology, Fred Hutchinson Cancer Research Center, Seattle, WA, United States, 2University of Washington, Seattle, WA, United States, 3Sangamo Biosciences, Richmond, CA, United States

Session P-F7 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM  Exhibit Hall A
Effect of ART On Persistence
420 Patterns of Persistent Viremia After 10 Years of Suppressive ART: ACTG A5276s
Sharon A. Riddler1, Evgenia Aga2, Ronald Bosch2, Joseph J. Eron3, Rajesh Gandhi4, Barbara Bastow5, Margaret Bedison2, David Vagratian6, John W. Mellors7, A5276s Protocol Team
1Infectious Diseases, Hospital Ramón y Cajal, Madrid, Spain, 2Burnet Institute, Melbourne, Australia, 3Hospital Ramón y Cajal, Madrid, Spain, 4Infectious Diseases, Massachusetts General Hospital, Boston, MA, United States, 5Social & Scientific Systems, Inc., Silver Spring, MD, United States, 6Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, United States

421LB Comparison of Combination ART Regimens for Viral Suppression in SIV-infected Rhesus Macaques
G. Del Prete1, R. Geleziunas1, J. Hesselgesser1, B. Lu2, J. Hattersley2, B. Lu2, J. Zheng3, J. Smedley3, M. Platia4, J. D. Lifson5
1AIDS and Cancer Virus Program, Leidos Biomedical Research, Inc., Frederick, MD, United States, 2Gilead Sciences, Inc., Foster City, CA, United States, 3Laboratory Animal Sciences Program, Leidos Biomedical Research, Inc., Frederick, MD, United States

422 Impact of RAL/MVC Intensification With or Without HIV-1aD5 Vaccination On HIV DNA: ERAMUNE 02 Study
Chad Achenbach1, Steven Deeks2, Timothy Wilkin3, Baiba Berzins4, Joseph Casazza5, Sidonie Lambert6, Lambert Assoumou7, Christine Katlama8, Brigitte Autran9, Robert Murphy10, the ERAMUNE 02 Study Group
1Northwestern University, Chicago, IL, United States, 2University of California San Francisco, San Francisco, CA, United States, 3Cornell University, New York, NY, United States, 4National Institutes of Health/Vaccine Research Center, Bethesda, MD, United States, 5Hospital Pitë-Salpêtrière, Paris, France, 6Université Pierre et Marie Curie (UPMC), Paris, France

423 Impact of Three Different ART Regimens On the GALT: A Randomized Clinical Trial
Sergio Serrano-Villar1, Talia Saino2, Anthony Albani3, Tammy Yotter4, Paolo Troia-Cancio5, Steve Deek6, Elizabeth Sinclair7, Darin Lartimore8, Alan C. Lederman9, Jianbin Wang2, Max W. Richardson3, Andrea P. O’Jordon1, Jeffrey Martin3, Steven G. Deeks4, Alan Landay5
1Infectious Diseases, Hospital Ramón y Cajal, Madrid, Spain, 2Burnet Institute, Melbourne, Australia, 3Hospital Ramón y Cajal, Madrid, Spain, 4Infectious Diseases, Monash University, Burnet Institute and Alfred Hospital, Melbourne, Australia

424 HIV Reservoir Changes in Resting CD4 Subsets in the IL7 Plus ART Intensification Eramune-01 Study
Manuela Pogliaghi1, Sidonie Lambert2, Lambert Assoumou3, Rima Zoorob4, Laura Papagn05, François Lecardenne6, Vincent Calvez7, Christine Katlama8, Brigitte Autran8, The Eramune-01 Study Group
1UPMC University Paris 06, UMR-S945, Laboratory of Immunity and Infection, Paris, France, 2University Vita-Salute, San Raffaele Scientific Institute, Milan, Italy, 3UPMC University Paris 06, INSERM, UMR-S943, Epidemiology, Therapeutic Strategies and Clinical Virology in HIV Infection, Laboratory of Virology, Paris, France, 4AP-HP, Pitë-Salpêtrière Hospital, Department of Virology, Paris, France, 5UPMC University Paris 6, INSERM, UMR-S943, Epidemiology, Therapeutic Strategies and Clinical Virology in HIV Infection, Center of Methodology, Paris, France, 6ORVACS, Pitë-Salpêtrière Hospital, Paris, France, 7AP-HP, Pitë-Salpêtrière Hospital, Department of Infectious and Tropical Diseases, Paris, France

425LB Pre-ART HIV-1 RNA as well as On-Treatment CD8 Count and CD4/CD8 Ratio Predict Residual Viremia On ART
Sharon A. Riddler1, Evgenia Aga2, Ronald Bosch7, Barbara Bastow3, Margaret Bedison4, David Vagratian5, Joseph J. Eron6, Rajesh Gandhi4, John W. Mellors7, for the ACTG A5276s Protocol Team
1Infectious Diseases, University of Pittsburgh, Pittsburgh, PA, United States, 2Statistical & Data Analysis Center, Harvard School of Public Health, Boston, MA, United States, 3Social & Scientific Systems, Inc., Silver Spring, MD, United States, 4Medicine/Infectious Diseases, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 5Medicine/Infectious Diseases, Massachusetts General Hospital, Boston, MA, United States

Session P-F8 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM Exhibit Hall A
Immunology for Cure
426 Eradication of HIV-1 Reservoirs With Antibody Mediated Killing
Zelda Euler1, Seoy H. Ly2, Matthew Hurt3, Athi M. N. Tisbis3,4, Gallai4
1Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States, 2Division of Infectious Diseases, Brigham and Women’s Hospital, Boston, MA, United States, 3Harvard Medical School, Boston, MA, United States

427LB Maraviroc Reverts Latent HIV-1 in ART Suppressed Patients Through NFKB Without Viral Load Increase
Nadia Madrid-Elena1, Beatriz Hernández-Novoa2, Beatrice Sastre Turrión3, Sergio Serrano-Villar4, Ajantha Solomon4, Carolina Gutierrez4, Javier Zamora4, Laura Garcia-Bermejo4, Sharon R Lewin5, Santiago Moreno6
1Infectious Diseases, Hospital Ramón y Cajal, Madrid, Spain, 2Burnet Institute, Melbourne, Australia, 3Hospital Ramón y Cajal, Madrid, Spain, 4Infectious Diseases, Monash University, Burnet Institute and Alfred Hospital, Melbourne, Australia

428 Regulatory B cells Attenuate Anti-HIV CTL Responses After Reactivation of Latent Reservoirs
Basile Siewe1, Jennifer Wallace1, Sonja Rygielski1, Jack T. Stapleton1, Jeffrey Martin1, Steven G. Deeks2, Alan Landay3
1Rush University Medical Center, Chicago, IL, United States, 2Iowa City Veterans Affairs Medical Center and the University of Iowa, Iowa City, IA, United States, 3Rush University Medical Center, San Francisco, CA, United States, 4HIV/AIDS Division, San Francisco General Hospital, University of California, San Francisco, CA, United States

429 Evaluation of HIV-1 Reservoir Characteristics in a Therapeutic HIV-1 Gag Vaccine Trial
Jonathan Z. Li1, Andrea Heiley2, Hayat Ahmed3, Michael M. Lederman4, Hongying Wang2, Zhong Zeng5, Robert T. Schooley6, Daniel R. Kuritzkes1, the ACTG A5197 Study Team
1Infectious Diseases, Hospital Ramón y Cajal, Madrid, Spain, 2Burnet Institute, Melbourne, Australia, 3Case Western Reserve University, Cleveland, OH, United States, 4Harvard School of Public Health, Boston, MA, United States, 5University of California San Diego, La Jolla, CA, United States

430LB Engineered TCR-Redirected Clearedom of Gag-Positive Reservoir Cells From ART-Treated Subjects
Hongbing Yang1, Sandrine Buissin2, Gemma Hancock2, Rebecca Ashfield2, Annelise Vudipot2, Tara M. Mahon3, Peter E. Molloy3, Namir Hassan4, Bert K. Jakobsen5, Lucy Dorrell6
1University of Oxford, Oxford, United Kingdom, 2Immuneure Ltd, Abingdon, Oxon, United Kingdom

431 Cross-Clade Inhibition of HIV On Primary Cells by CXCXR4 or CCR5 Fused To the C34 Peptide From gp41 HR2
George J. Leslie1, Jianbin Wang2, Max W. Richardson3, Andrea P. O. Jordan4, Philip D. Gregory5, James L. Riley5, Michael C. Holmes6, James A. Hoxie6
1Medicine, University of Pennsylvania, Philadelphia, PA, United States, 2Sangamo Biosciences, Inc, Richmond, CA, United States, 3Microbiology, University of Pennsylvania, Philadelphia, PA, United States
Session P-F9 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM  Exhibit Hall A

Toward A Cure...

432LB Ing-B a Potential PKC Activator for HIV Eradication Is Active in SIVmac251-Infected Macaques
Amilcar Tanuri1,2, Lucio Gama3, Renato Santana4,5, Mark Lewis6, Andrea Savarino7, Iart Shytaj1, Janice E. Clements2, Luiz F. Planowski3
1Genetics, UFRJ, Rio de Janeiro, Brazil, 2UFRJ, Rio de Janeiro, Brazil, 3Johns Hopkins School of Medicine, Baltimore, MD, United States, 4BioQual, Inc, Rockville, MD, United States, 5Istituto Superiore di Sanità, Rome, Italy, 6KyroLab, Valinhos, Brazil

434 SAHA Dampens TCR-Mediated Reactivation of Latently Infected Cells
Pejman Mohammadi1,2, Julia di Iulio1,2, Miguel Munoz2, Niko Beerweninkel1,2, Amalio Telenti1, Angela Ciuffi1
1Department of Biosystems Science and Engineering, ETH Zurich, Basel, Switzerland, 2Swiss Institute of Bioinformatics, Basel and Lausanne, Switzerland, 3Lausanne University Hospital and University of Lausanne, Institute of Microbiology, Lausanne, Switzerland

435LB HIV-1 Expression Within Resting CD4 T-Cells Following Multiple Doses of Vorinostat in Vivo
Yang Kuo-Hsiung1, Nancie M. Archiri2, Christopher H. Woelk3, Matthew C. Strain1, Douglas D. Richmar1, JuAnn D. Kuruc4, Richard J. O. Barnard1, Daria J. Hazuda5, Joseph J. Erro1, David M. Margolis6
1School of Pharmacy, UNC Chapel Hill, Chapel Hill, NC, United States, 2School of Medicine, UNC Chapel Hill, Chapel Hill, NC, United States, 3University of Southampton, Southampton, United Kingdom, 4School of Medicine, UCSD and San Diego VAMC, San Diego, CA, United States, 5Merck Research Laboratories, White Horse Junction, PA, United States

436 Autophagy induction by Histone Deacetylase Inhibitors Inhibits HIV-1 Infection in Macrophages
Grant R. Campbell, Rachael S. Bruckman, Stephen A. Spector
University of California San Diego, La Jolla, CA, United States

437 An In Vitro Compound Screen for Selective Apoptosis Induction in HIV-1 Infected Resting CD4+ T Cells
Adam M. Spivak1, Alberto Bosque2, Vicente Panellanes2
1Medicine, University of Utah School of Medicine, Salt Lake City, UT, United States, 2Pathology, University of Utah School of Medicine, Salt Lake City, UT, United States

438LB Panobinostat Induces HIV Transcription and Plasma Viremia in HIV Patients on Suppressive cART
Thomas Rasmussen, and the CLEAR study group
Dept. of Infectious Diseases, Aarhus University Hospital, Aarhus, Denmark

439 Failure of HIV-1 To Replicate in Human T Cells Expressing a Tat Mutant
David Harrich, Hongqing Jin, Lina Rustandi, Ann Apolloni, Haran Sivakumar, Min-Hsuan Lin, Dongsheng Li, Ting Wei
Cell and Molecular Biology, QIMR Berghofer, Herston, QLD, Australia

440 Hepatitis C Therapy Reduces CD4 T-Cell-Associated HIV-1 DNA in HIV-1/HCV Coinfected Patients
Hong Sun1,2, Maria Buzon1,3, Amy Shaw1, Randi Berg1, Xu G. Yu1, Sara Ferrando-Martinez1,2, Manuel Leal1,2, Ezequiel Ruiz-Matteoi1,2, Matthias Lichterfeld1
1Ragon Institute of MGH, MIT, and Harvard, Boston, MA, United States, 2Key Laboratory of AIDS Immunology, Department of Laboratory Medicine, First Affiliated Hospital of China Medical University, Shenyang, China, 3Infectious Disease Division, Massachusetts General Hospital, Boston, MA, United States, 4Infectious Disease Division, Aarhus University Hospital Skejby, Aarhus, Denmark, 5Laboratory of Immunobiology, Biomedical Institute of Seville, Division of Infectious Diseases, Microbiology and Preventive Medicine, Virgen del Rocio University Hospital, University of Seville, Seville, Spain, 6Laboratorio Inmunobiologia Molecular, Hospital General Universitario Gregorio Maranon, Madrid, Spain, 7Consejo Superior de Investigaciones Cientificas, Madrid, Spain

441 HIV-1 Nef Inhibits Autophagy in Macrophages Through Transcription Factor EB Sequestration
Grant R. Campbell, Pratima Rawat, Rachel S. Bruckman, Stephen A. Spector
University of California San Diego, La Jolla, CA, United States

Session P-G1 Poster Session
Tuesday March 4, 2014, 2:30 PM–4:00 PM  Exhibit Hall A

CNS Viral Escape and Neuroinflammation On ART

442 HIV-1 RNA Detection in CSF in ART-Treated Subjects With Incomplete Viral Suppression in Plasma
Sam Nightengale, the PARTITION Study Group
Institute of Infection and Global Health, University of Liverpool, Liverpool, United Kingdom

443 CSF Viral Escape in Patients Without Neurological Disorders: Prevalence and Associated Factors
Carmela Pinnetti1, Patrizia Lorenzin2, Federica Forbici3, Adriana Ammassari4, Raffaella Libertone1, Maria Letizia Giancola5, Maria Rosaria Capobianchi6, Carlo Federico Peroni7, Andrea Amini8
1National Institute for Infectious Disease, Rome, Italy, 2University of Rome, Rome, Italy

444 Early Monocyte Inflammation Among Treatment-Naive Acute HIV-Infected Thai Subjects
Lishomwia C. Ndhiwia1, Mary Margaret Byron2, Guangxiang Zhang3, Duangnathai Suthichon4, Somprath/Shana Rattanamanee5, Rapee Trichawong6, Nittaya Phanuphak7, Victor Valcour8, Merlin Rober9, Jintanat Ananworanich10
1Hawaii Center for AIDS, University of Hawaii, Honolulu, HI, United States, 2University of Hawaii, Honolulu, HI, United States, 3SEARCH, The Thai Red Cross AIDS Research Center, Bangkok, Thailand, 4Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, 5University of California San Francisco, San Francisco, CA, United States, 6US Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States, 7SEARCH, HIV-NAT, The Thai Red Cross AIDS Research Center, Bangkok, Thailand

445 Cerebrospinal Fluid Viral Blips and Persistent Escape in HIV-Infected Patients On ART
Arvid Eden1, Lars-Magnus Andersson2, Dietmar Fuchs3, Lars Hagberg4, Staffan Nilsson4, Bo Svennerholm5, Aylin Yilmaz6, Henrik Zetterberg7, Magnus Gisslen7
1University of Gothenburg, Gothenburg, Sweden, 2Innsbruck Medical University, Innsbruck, Austria, 3Chairmer University of Technology, Gothenburg, Sweden

446 Mitochondrial DNA Is Associated With Inflammation and Neurocognitive Deficits in HIV Infection
Josué Pérez-Santiago1, Sanjay R. Mehta1, Sara Gianella2, Rachel D. Schrier1, Mariana Cherner1, Susanna R. Var1, Tyler R. C. Day1, Miguel Ramirez-Gaona2, Davey M. Smith1,2, Scott L. Letendre1
1Medicine, University of California San Diego, La Jolla, CA, United States, 2Biobinnomics, University of Alberta, Edmonton, AB, Canada, 3Veterans Administration San Diego Healthcare System, San Diego, CA, United States

447 CNS Outcomes of cART vs. cART plus Maraviroc and Raltegravir Intensification During Acute HIV
Victor Valcour1, Serena Spudich2, Napapon Sallasuta3, Sukalaya Lerdthum4, James L. K. Fletcher1, Eugene D. M. B. Kroon5, Peei Marangu1, Bonnie Sliket1, Jerome Kim1, Jintanat Ananworanich1, on behalf of the SEARCH 010/ RV254 Study Group
1Memory and Aging Center, UCSF, San Francisco, CA, United States, 2Neurology, Yale University, New Haven, CT, United States, 3Huntington Medical Research Institutes, Pasadena, CA, United States, 4Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, 5SEARCH, The Thai Red Cross AIDS Research Center, Bangkok, Thailand, 6U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Springs, MD, United States, 7Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand

CROI 2014
448 The Effects of Age and Study Cohort On Brain Structure Among Men With HIV Disease
James T. Becker1, Lawrence A. Kingsley2, Mikhail Popov3, Nisha Shah4, Andrew J. Levine5, Eileen M. Martin6, Eric N. Miller7, Cynthia A. Munro8, Ann Rager9, Ned Sacker10
1Psychiatry, Neurology, Psychology, University of Pittsburgh, Pittsburgh, PA, United States, 2Infectious Diseases and Microbiology, Epidemiology, University of Pittsburgh, Pittsburgh, PA, United States, 3Psychiatry, University of Pittsburgh, Pittsburgh, PA, United States, 4Epidemiology, The John Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, 5Neurology, University of California Los Angeles, Los Angeles, CA, United States, 6Psychiatry, Rush University School of Medicine, Chicago, IL, United States, 7Psychiatry, University of California Los Angeles, Los Angeles, CA, United States, 8Psychiatry, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, 9Radiology, Northwestern University, Evanston, IL, United States, 10Neurology, The Johns Hopkins University School of Medicine, Baltimore, MD, United States

449 FMRI Reveals Asymptomatic Deficits Among HIV+ Older Adults On cART When Compared To HIV- Controls
Manya Magnus1, Rebecca Barazay2, Halli Olsen3, Xiong Jiang4
1Epidemiology and Biostatistics, George Washington University, Washington, DC, United States, 2Georgetown University, Washington, DC, United States

450 Longitudinal Progression of Cortical Atrophy in HIV-Patients On Stable Treatment
Michael R. Nowak1, Bradford Navi2, Jaroslav Harezlak3, Constantin Yiannoutsos4, Charles Guttmann5, Elyse Singer6, Thomas Campbell7, Eric Daar8, Giovanni Schifitto9, David Tate10
1Department of Computer Science and Engineering, Texas A&M University, College Station, TX, United States, 2Tufts University Medical School, Boston, MA, United States, 3Indiana University School of Medicine, Indianapolis, IN, United States, 4Brigham and Women’s Hospital, Boston, MA, United States, 5University of California Los Angeles, Los Angeles, CA, United States, 6University of Colorado, Denver, CO, United States, 7University of Rochester Medical Center, Rochester, NY, United States, 8LUR for the Advancement of Military Medicine, San Antonio, TX, United States

451 FMRI Evidence for HIV-Induced Acceleration of Aging in Middle-Aged Women
Xiong Jiang1, Chenglong Liu2, Matthew Leclair2, Cuiwei Wang2, Xiaohan Xu2, Pilar Hamilton3, Lakshmi Goparaju4, Mary Young5
1Neuroscience, Georgetown University Medical Center, Washington, DC, United States, 2Georgetown University Medical Center, Washington, DC, United States

452 Factors Related To Brain Atrophy in a Cohort of HIV Infected Patients: ANRS CO3 Aquitaine Cohort
Carole Dufouil1, Laura Richet1, Rodolphe Thibault1, Mathias Bruyant1, Frédéric Dauchy2, Michèle Allard3, Didier Neau4, François Dabis5, Fabrice Bonnet6, Geneviève Chêne7
1INSERM U1027, BIOMEDTIC Laboratory, University of Bordeaux, Bordeaux, France, 2ANRS CO3 Aquitaine Cohort, Bordeaux, France, 3Bordeaux Hospital, Bordeaux, France

453 Hyperphosphorylated Tau in Cerebrospinal Fluid: A Biomarker for Neurological Aging in HIV-1?
Jan J. Krut1, Magnus Gislen2, Lars Hagberg3, Henrik Zetterberg4, Richard W. Price5, Staffan Nilsson6, Paola Cinque7
1Infectious Diseases, Sahlgrenska Academy, Gothenburg, Sweden, 2Psychiatry and Neurochemistry, Institute of Neuroscience and Physiology, University of Gothenburg, Gothenburg, Sweden, 3Neurology, University of California San Francisco, San Francisco, CA, United States, 4Mathematical Sciences, Chalmers University of Technology, Gothenburg, Sweden, 5Infectious Diseases, San Raffaele Hospital, Milan, Italy

454 Efavirenz Produces a Differential Bioenergetic Response in Neurons and Glial Cells
Haryes A. Funes1, Nadezda Apostolova2, Fernando Alegre3, Miriam Polo4, Ana Blas-Garcia4, Juan V. Esplugues5
1Departament de Farmacologia, Facultat de Medicina, Universitat de Valencia, Valencia, Spain, 2University Hospital Dr. Peset, Valencia, Spain, 3University Hospital Dr. Peset, Valencia, Spain

455 Corneal Sensory Nerve Fiber Loss in SIV-Infected Macaques: Tracking HIV PNS Damage
Jamie Dorsey1, Lisa Mangus1, Jonathan Oakley2, Joseph Mankowski1, 3
1Molecular and Comparative Pathobiology, Johns Hopkins University, Baltimore, MD, United States, 2Voxelion, Pleasanton, CA, United States, 3Neurology, Johns Hopkins University, Baltimore, MD, United States

456 HIV-Tat Protein in Inflammatory Infiltrates of CNS-IRIS and in CSF of Patients On ART
Gloria von Geldern1, Troy P. Johnson2, Richa Sacktor3, Justin C. McArthur4, Scott Letendre5, Avindra Nath6
1NINDS, NIH, Bethesda, MD, United States, 2Dept. of Neurology, Johns Hopkins University, Baltimore, MD, United States, 3Dept. of Neurology, Johns Hopkins University, Baltimore, MD, United States, 4Dept. of Neurology, University of California, San Diego, San Diego, CA, United States

457 Central Nervous System Demyelination in Pediatric SIV Infection
Herman Kamboj1, Kimberly Curtis2, Heather Carry3, Hayford Agymang4, Koen Van Rompay5, Kristina Abel6, Mark Burke1
1Physiology & Biophysics, Howard University, Washington, DC, United States, 2University of California Davis, Davis, CA, United States, 3University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

458 Brain Iron Transport Is Associated With Neurocognitive Performance in HIV/AIDS
Asha R. Kallianpur1, James R. Connor2, Christopher C. Coe3, Benjamin B. Gelman4
1Genomic Medicine, Cleveland Clinic Foundation/Lerner Research Institute, Cleveland, OH, United States, 2Neurosurgery, Penn State Milton S. Hershey Medical Center, Hershey, PA, United States, 3Psychology, University of Wisconsin, Madison, WI, United States, 4Pathology, University of Texas Medical Branch, Galveston, TX, United States

460 HIV-Associated Neurocognitive Disorders Display a Distinct MicroRNA Profile in Plasma
Eugene L. Asahchop1, David Broadhurst1, John Gill2, Christopher Power1, 3
1Medicine, University of Alberta, Edmonton, AB, Canada, 2Medicine, University of Calgary, Calgary, AB, Canada

461 Cognitive and Brain Microstructure Abnormalities in HIV-1 Infected Humanized Mice
Prasanta K. Dash1, Michael D. Boska2, Sidra P. Akhter2, Jaclyn S. Knibbe2, Adrian A. Epstein3, Robin R. High4, Harris A. Gelbard5, Larisa Y. Poluektova5, Howard E. Gendelman6, Santhi Gorantla1, Nadezda Apostolova1, Fernando Alegre2, Miriam Polo1, Ana Blas-Garcia4, Juan V. Esplugues5
1Pharmacology and Expt, Neuroscience, University of Nebraska Medical Center, Omaha, NE, United States, 2Radiology, University of Nebraska Medical Center, Omaha, NE, United States, 3University of Rochester Medical Center, NY, NY, United States

462 SIV Dynamics in the CD8-Depleted vs Non-CD8-Depleted Rhesus Macaque Model for NeuroAIDS
Susanna L. Lamers1, David J. Nolan2, Brittany D. Rife3, Gary B. Fogel4, Tricia Burdo5, Kenneth C. Williams6, Marco Salemi7
1Bioinfoexperts, LLC, Thibodaux, LA, United States, 2Department of Pathology, Immunology, and Laboratory Medicine, University of Florida, Gainesville, FL, United States, 3University of South Florida, Gainesville, FL, United States, 4Natural Selection, San Diego, CA, United States, 5Boston College, Boston, MA, United States

463 Vascular Endothelium and Neurological Performance During Primary HIV Infection
Sebastian Urday1, Kevin Robertson2, Fang-yong Li3, Felicia C. Chow3, Julia Peterson2, Elaine M. Nitta2, Richard W. Price4, Priscilla Y. Hsue4, Serena Spudich1
1Medicine, University of Florida, Gainesville, FL, United States, 2Medicine, University of Alberta, Edmonton, AB, Canada, 3Medicine, University of Calgary, Calgary, AB, Canada

Session P-G2 Poster Session
Tuesday March 4, 2014, 2:30 pm–4:00 pm Exhibit Hall A
HAND in Aging Populations

Session P-G3 Poster Session
Wednesday March 5, 2014, 2:30 pm–4:00 pm Exhibit Hall A
Neuropathogenesis
Session P-G4 Poster Session
Wednesday March 5, 2014, 2:30 pm – 4:00 pm **Exhibit Hall A**

Host Genetics in HAND

464 Heme Oxygenase-1 Polymorphism and Protein Deficiency Associated With Neurological Disease in HIV

Alexander J. Gill1, Suren S. Ambegaokar1, Colleen E. Kovacsics1, Stephanie A. Cross2, Benjamin B. Gelman3, Dennis L. Kolson4

1Department of Neurology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, United States, 2Department of Pathology, University of Texas Medical Branch, Galveston, TX, United States

465 Mitochondrial DNA Haplogroups and Neurocognitive Impairment in the CHARTER Cohort

Todd Huglan1, David Samuels1, William Bush1, Ronald Ellis2, Scott Letendre2, Peter Straub3, Deborah Murdoch3, Donald Franklin3, Igor Grant3, Asha Kallianpur4, for the CNS HIV Antiretroviral Therapy Research (CHARTER) Group

1Vanderbilt University, Nashville, TN, United States, 2University of California San Diego, San Diego, CA, United States, 3Cleveland Clinic Foundation/Lerner Research Institute, Cleveland, OH, United States

466 MBL2 Promoter Polymorphism rs7096206 Predicts Brain Metabolite Anomalies in HIV-Infected Adults

Kumud K. Singh1, Qianqian Deng1, Christine Fennema-Notestine1, Florin Vaida1, Ronald J. Ellis1, Scott L. Letendre2, Donald Franklin2, Debralee Rosario1, Robert K. Heaton1, Igor Grant3, and CHARTER Group

1University of California San Diego, La Jolla, CA, United States

Session P-G5 Poster Session
Wednesday March 5, 2014, 2:30 pm – 4:00 pm **Exhibit Hall A**
PML and Other CNS Infections

467 Pathogenesis of JC Virus Reactivation During Natalizumab Treatment

Spyridon Chalkias1, Xin Dang1, Evelyn Bord1, Marion Steijn1, Philip Kinkel2, Jacob Sluiter3, Maria Houtchens4, Guy Buckle5, Carolina Ionenf6, Igor Korahnik7

1Harvard Medical School, Center for Virology and Vaccine Research, Boston, MA, United States, 2Department of Neurology, Brandeis, Boston, MA, United States, 3Department of Neurology BWH, Boston, MA, United States, 4Department of Neuroscience, UMass, Worcester, MA, United States

468 Impaired T. pallidum Opsonic Antibody Function in HIV-Infected Patients With Neurosyphilis

Christina Marra1, Lauren Tantalo1, Sharon Sahi2, Emily Ho3, Sheilla Dunaway4, Trudy Jones5, Sheila Lukehart6

1University of Washington, Seattle, WA, United States

469 Significance of Plasma JCV-DNA in HIV Progressive Multifocal Leukenoencephalopathy (PML)

Francesca Ferretti1, Manuela Testa1, Valeria Longo2, Constantine Theodore Yuannoti2, Beverley Sue Musick3, Annamaria Pazzi1, Antonio Boschini1, Simona Bossolasco1, Adriano Lazzarin1, Paola Cinque1

1San Raffaele Scientific Institute, Milan, Italy, 2Department of Biostatistics, 3University of Sao Paulo, Sao Paulo, Brazil, 4New England Primate Research Center, Southborough, MA, United States

Session P-G6 Poster Session
Wednesday March 5, 2014, 2:30 pm – 4:00 pm **Exhibit Hall A**

CNS Viral Genetics

470 CD4-Independent Infection in the CNS of RS SHIV+ Macaques Is Associated With Severe Neuropathology

Ana Rachel Leda1,2, Ke Zhuang1, Lily Tsai1, Agegnehu Gett2, Heather Knight1, Carole Harbison1, Susan Westmoreland2, Cecilia Chong-Mayer1

1Aaron Diamond AIDS Research Center, New York, NY, United States, 2Federal University of Sao Paulo, Sao Paulo, Brazil, 3New England Primate Research Center, Southborough, MA, United States

471 HIV-Associated Neurocognitive Disorder Is Associated With HIV-1 Dual Infection

Gabriel A. Wagner1, Antoine Challion1, Donald R. Franklin2, Gemma Caballero3, Sergei L. Kosevsky Pond3, Robert K. Heaton3, Douglas D. Richman1,2, Davey M. Smith2,3, for the CHARTER Group

1Infectious Diseases, University of California San Diego, La Jolla, CA, United States, 2University of California San Diego, La Jolla, CA, United States, 3Veterans Affairs San Diego Healthcare System, San Diego, CA, United States

472 Single-Genome Analysis Reveals Genetic Characteristics of Neuroadaptation Across HIV-1 Envelope

Teresa H. Evening1, Leslie St. Bernard1, Charles Farmer1, Mark Markowitz1

The Aaron Diamond AIDS Research Center, New York, NY, United States

Session P-G7 Poster Session
Thursday March 6, 2014, 2:30 pm – 4:00 pm **Exhibit Hall A**

ART Effects On HAND and CNS Reservoirs

473 HIV-1 Replication in Central Nervous System Increases Over Time On Protease Inhibitor Only Therapy

Christoph Stephan1, Maximilian Donath1, Timo Wolf1, Annette Haberl1, Markus Bickel1, Siri Göpel1, Pavel Khaykin1, Annemarie Berger1, Dimitra Bon1, Reinhard Brott2

1Infectious Diseases, Goethe-University Hospital, Frankfurt, Germany, 2Medical Virology Institute, Goethe-University Hospital, Frankfurt, Germany

Tanja Su1, Judith Schouten2, Gert J. Geurtse1, Ferdinand W. Wit3,4, Ineke G. Stolte3,4, Peter Fortegestes3,5, Matthias W. A. Caan6, Peter Reiss1,7, Charles B. Majewski1, Ben A. Schmidt8, for the AGSHIV Cohort Study Group

1Radiology, Academic Medical Center, Amsterdam, Netherlands, 2Neurology, Academic Medical Center, Amsterdam, Netherlands, 3Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, 4Internal Medicine, Academic Medical Center, Amsterdam, Netherlands, 5GSD Amsterdam, Amsterdam, Netherlands, 6Neurology, Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands, 7Psychology, University of Amsterdam, Amsterdam, Netherlands

476 Improvement of Depression and Anxiety After Discontinuation of Long-Term Efavirenz Treatment

Khusro M. Mothapo1, Amt Schellekens2, Reinout van Crevel1, Karin Grintjes-Huisman1, Monique Keuter1, Peter Koopmans2, Andre van der Ven2

1Internal Medicine and Nijmegen Institute for Infection, Inflammation and Immunity, Radboud University Medical Center, Nijmegen, Netherlands, 2Neuropsychiatry, Radboud University Medical Center, Nijmegen, Netherlands

477 New Advanced EEG Technique To Monitor Early Brain Damage in Naïve HIV and Its Recovery During ART

Massimo Andreoni1, Claudio Babiloni1,2, Paola Maria Rossini3, Paolo Onorati3, Stefano Ferracuti4, Francesco Di Campli5, Antonio Aceti5, Elisabetta Teli6, Alfredo Pennica7

1Clinical Infectious Diseases, Tor Vergata University, Rome, Italy, 2Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Italy, 3Department of Neuroscience, San Raffaele Pisana, Rome, Italy, 4Institute of Neurology - Department of Geriatrics, Catholic University Sacro Cuore, Rome, Italy, 5Biophysics and Pharmacology, Sapienza University of Rome, Rome, Italy, 6Psychiatry, Sapienza University of Rome - S. Andrea Hospital, Rome, Italy, 7Psychiatry, Sapienza University of Rome, Rome, Italy, 8Clinical Infectious Diseases, Sapienza University of Rome - S. Andrea Hospital, Rome, Italy

478 HIV-Replication Control Rates Needed To Prevent Neurocognitive Performance (NP) Decline

Ignacio Pérez-Valero1, Robert Heaton1, Donald Franklin2, Scott Letendre2, Reena Deutsch2, Bernard Gelman3, David Simpson3, Ann Collier1, Igor Grant3, and the CHARTER Group

1Hospital Universitario La Paz, Madrid, Spain, 2University of California San Diego, San Diego, CA, United States, 3University of California San Diego, San Diego, CA, United States, 4Hospital Universitario La Paz, Galveston, TX, United States, 5Mount Sinai Hospital, New York, NY, United States, 6University of Washington, Seattle, WA, United States
479 CSF Biomarker Profile in HIV Patients With and Without CSF Viral Escape
Ignacio Pérez-Valero1, Scott Letendre2, Robert Heaton1, Ronald Ellis2, Allen McCutchan1, David Simpson1, Reena Deutsch1, Igor Grant3, for the CHARTER Group
1Hospital Universitario La Paz, Madrid, Spain, 2University of California San Diego, San Diego, CA, United States, 3Mount Sinai School of Medicine, New York, NY, United States

480 Accuracy of NEU Screen for Detecting Cognitive Impairment in Virologically Suppressed HIV Patients
Jose A. Muñoz-Moreno1, Anna Prats1, Núria Pérez-Álvarez1, Inmaculada Nieto-Verdugo1, Carmina R. Fumaz1, Maria J. Ferrer1, Maite Gardeira2, Bonaventura Clotet1,3
1Luita contra la SIDA Foundation - Germans Trias i Pujol University Hospital, Badalona, Barcelona, Catalonia, Spain, 2Inserm 1059 - INSERM, Montpellier, France, 3Institut per la Recerca de la SIDA IrsiCaixa, Badalona, Barcelona, Catalonia, Spain

481 Determinants of Cognitive Impairment in HIV-Positive Men On cART and Uninfected Controls
Judith Schouten1,2, Tanja Su1, Ferdinand W. Wit1,4, Neeltje A. Kootstra3, Matthijs W. A. Caan1, Gert J. Geurtsen1, Ben A. Schmand1, Charles B. Majoie1, Peter Portegies1, Peter Reiss1,5, on behalf of the AGEMIVH Cohort Study Group
1Neurology, Academic Medical Center, Amsterdam, Netherlands, 2Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, 3Psychology, Academic Medical Center, Amsterdam, Netherlands, 4Experimental Immunology, Academic Medical Center, Amsterdam, Netherlands, 5Psychology, University of Amsterdam, Amsterdam, Netherlands

482 HIV Reactivation by the Histone Deacetylase Inhibitor Panobinostat: Effects On CNS
Thomas A. Rasmussen1, Ole S. Segaard1, Holger J. Møller1, Christel R. Brinkmann1, Rikke Olesen1, Alex L. Laursen1, Lars Østergaard1, Martin Tolstrup1
1Infectious Diseases, Aarhus University Hospital, Aarhus, Denmark, 2Clinical Biochemistry, Aarhus University Hospital, Aarhus, Denmark

483 Exporatory Pharmacology of TB and HCV Coinfection
Juan M. Tiraboschi1, Jose Muñoz-Moreno2, MC Puertas3, Carlos Alonso2, Anna Prats-Paris1, Elena Ferrer1, Nerea Rozas1, Marga Maso-Serra1, Javier Martínez-Picado1, Daniel Podzamczer1
1HIV Unit, Infectious Disease Service, Hospital Universitari de Bellvitge, Barcelona, Spain, 2Fundación Uitua contra la SIDA - Unitat de VIH, Hospital Universitari Germans Trias i Pujol, Barcelona, Spain, 3Institut de Recerca de la SIDA IrsiCaixa, Barcelona, Spain, 4Complex Sanitari Santa Tecla, URV, Tarragona, Spain

484 Differences Between Cerebrospinal Fluid and Blood Biomarkers of Inflammation in HIV Infection
Julia Peterson1, Sheila Keating2, Dietmar Fuchs3, Philipp Norris4, Henrik Zetterberg3, Barbara Shacklett5, Serena Spudich6, Magnus Gisslén7, Richard W. Price1
1Neurology, University of California San Francisco, San Francisco, CA, United States, 2Blood Systems Research Institute, San Francisco, CA, United States, 3Center for Chemistry and Biomedicine, Innsbruck Medical University, Innsbruck, Austria, 4Chalmers University of Technology, Gothenburg, Sweden, 5University of California Davis, Davis, CA, United States, 6Psychiatry, University of California San Diego, La Jolla, CA, United States, 7Neurology, University of California San Diego, La Jolla, CA, United States

485B Neuroinflammation in Asymptomatic HIV-Infected Subjects On Effective cART
Jaime H. Vera1, Qi Guo1, Illan Rabiner1, Paul Matthews1, Roger Gunn1, Alan Winston1
1Infectious Diseases, Imperial College London, London, United Kingdom, 2Institute of Psychiatry, King’s College London, London, United Kingdom, 3Imanova Centre for Imaging Sciences, London, United Kingdom, 4Division of Brain Sciences, Imperial College London, London, United Kingdom

486 CSF Biomarkers Correlate With Magnetic Resonance Spectroscopy Metabolites During HIV Disease
Albert M. Anderson1,2, Christine Fenema-Notestine1, Anya Umlauf1, David Clifford1, Christina Marna1, Benjamin Gelman1, Justin McArthur2, Allen McCutchan1, Susan Moggrolo1, Scott Letendre3, for the CHARTER group
1Emory University School of Medicine, Atlanta, GA, United States, 2University of California—San Diego, San Diego, CA, United States, 3Washington University at St. Louis, St. Louis, MO, United States, 4University of Washington, Seattle, WA, United States, 5University of Texas Medical Branch, Galveston, TX, United States, 6Johns Hopkins University, Baltimore, MD, United States, 7Mount Sinai School of Medicine, New York, NY, United States

488 Abdominal Obesity, Inflammation, Immune Activation and Neurocognitive impairment
Fred R. Sattler1, Xiaolu He1, Scott Letendre2, Cara Wilson3, Chelsea Sanders1, Robert K. Heaton1, Ronald Ellis1, Donald Franklin4, Igor Grant5, J. Allen McCutchan1, for the CHARTER Group
1Medicine, University of Southern California, Los Angeles, CA, United States, 2Preventive Medicine, University of Southern California, Los Angeles, CA, United States, 3Medicine, University of California San Diego, La Jolla, CA, United States, 4Medicine, University of Colorado at Denver, Denver, CO, United States, 5Medicine, University of California San Diego, La Jolla, CA, United States, 6Psychiatry, University of California San Diego, La Jolla, CA, United States, 7Neurology, University of California San Diego, La Jolla, CA, United States

489 Blood Cell Indices and Neurocognitive Impairment in the HAART Era: A CHARTER Study
Asha R. Kallianpur1, Quan Wang2, Pelin Jia1, Justin C. McArthur3, Susan Moggrolo1, Ann C. Collier1, Benjamin B. Gelman4, David B. Clifford1, J. Allen McCutchan1, Igor Grant5, for the CHARTER Study Group
1Genomic Medicine, Lerner Research Institute, Medicine Institute, Cleveland, OH, United States, 2Biomedical Informatics, Vandenberg Air Force Base, Vandenberg, CA, United States, 3Infectious Diseases, Aarhus University Hospital, Aarhus, Denmark, 4Psychiatry, University of Southern California, Los Angeles, CA, United States, 5Neurology, University of California San Diego, La Jolla, CA, United States, 6Psychiatry, University of California San Diego, La Jolla, CA, United States, 7Neurology, Academic Medical Center, Amsterdam, Netherlands, 8Medicine/Infectious Diseases, University of California San Diego, La Jolla, CA, United States, 9Psychiatry, University of California San Diego, La Jolla, CA, United States

490 CNS Immunoactivation in HIV Patients On ART With HIV-Associated Mild Neurocognitive Impairment
Arvid Eden1, Donald R. Franklin2, Dietmar Fuchs2, Igor Grant3, Scott Letendre1, Thomas Marotta2, Staffan Nilsson4, Richard W. Price1, Henrik Zetterberg1, Magnus Gisslen5
1Neurology, University of Gothenburg, Gothenburg, Sweden, 2University of California San Diego, La Jolla, CA, United States, 3Inssbruck Medical University, Innsbruck, Austria, 4Chalmers University of Technology, Gothenburg, Sweden, 5University of California San Francisco, San Francisco, CA, United States

491 CNS Inflammation During Treatment-Induced Viral Suppression
Julia Peterson1, Sheila M. Keating2, Viktor Dahl3, Philip J. Norris4, Sarah Palmer5,6, Dietmar Fuchs7, Henrik Zetterberg1, Magnus Gisslén7, Richard W. Price1
1Neurology, University of California San Francisco, San Francisco, CA, United States, 2Blood Systems Research Institute, San Francisco, CA, United States, 3Karolinska Institute, Stockholm, Sweden, 4Westmead Millennium Institute for Medical Research and University of Sydney, Westmead NSW, Australia, 5Innsbruck Medical University, Innsbruck, Austria, 6University of California San Francisco, San Francisco, CA, United States

492 CSF Viremia and Immunoregulatory Markers in Pts With NCI On TDF/FTC/EFV and After Switch To ABC/3TC/MVC
Juan M. Tiraboschi1, Jose Muñoz-Moreno2, MC Puertas3, Carlos Alonso4, Anna Prats-Paris1, Elena Ferrer1, Nerea Rozas1, Marga Maso-Serra1, Javier Martínez-Picado1, Daniel Podzamczer1
1HIV Unit, Infectious Disease Service, Hospital Universitari de Bellvitge, Barcelona, Spain, 2Fundación Uitua contra la SIDA - Unitat de VIH, Hospital Universitari Germans Trias i Pujol, Barcelona, Spain, 3Institut de Recerca de la SIDA IrsiCaixa, Barcelona, Spain, 4Complex Sanitari Santa Tecla, URV, Tarragona, Spain

Session P-G8 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM Exhibit Hall A
CNS Inflammation, Immune Activation, and HAND Biomarkers

493 Rifapentine Once-Weekly Dosing Effect On Efavirenz, Emtricitabine and Tenofovir PKs
Christine Faren1, Severine Dornouain1, Cathy Cantalloube1, Laurent Perrin5, Virginie Esposito1, Isabelle Clieren-Puisieux1, Xavier Boulenç1, Marilyn Maroni1
1Disposition Safety Animal Research, Sanofi, Montpellier, France, 2Clinical Exploratory Pharmacology, Sanofi, Montpellier, France, 3Clinical Exploratory Pharmacology, Sanofi, Montpellier, France, 4Clinical Pharmacology of TB and HCV Coinfection

Session P-H1 Poster Session
Tuesday March 4, 2014, 2:30 PM–4:00 PM Exhibit Hall B
Clinical Pharmacology of TB and HCV Coinfection
494 Relationship Between Efavirenz Trough & CYP2B6 Genotypes With Rifampin-Based TB Therapy in STRIDE
Anne Luetkemeyer1, Susan L. Rosenkranz2, Darlene Lu3, Beatriz Grinstejn4, Jorge Sanchez5, Michael Ssemmmanda6, Ian Sanne7, Helen McIlleron8, Diane Havlir9, David Haas10, ACTG A5221 & A5243 Study Teams

1HIV/AIDS Division, San Francisco General Hospital, University of California San Francisco, San Francisco, CA, United States, 2Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, United States, 3HIV/AIDS Division, Center for Biostatistics in AIDS Research, Harvard School of Public Health, San Francisco, CA, United States, 4Instituto de Pesquisa Clinica Evandro Chagas, Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil, 5Associazione Civil Impacta Salud y Educacion, Lima, Peru, 6Joint Clinical Research Center, Kampala, Uganda, 7Clinical HIV Research Unit, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, 8Division of Clinical Pharmacology, University of Cape Town, Cape Town, South Africa, 9Vanderbilt University School of Medicine, Nashville, TN, United States

495 Concentrations of Nevirapine or Efavirenz On and Off Anti-Tuberculosis Therapy (ARNS12214)
Nilesh Bhatt1, Elisabeth Baudin2, Binidya Meggi3, Carlota Silva4, Valerie Furlan5, Aurelie Barnall-Tran6, Maryline Bonnet7, Anne-Marie Tabagro7
1Instituto Nacional de Saúde, Ministry of Health, Maputo, Mozambique, 2Clinical Research Department, Epicentre, MSF, Paris, France, 3Clinical Pharmacy, Hospital Bicêtre, Paris-Sud University, Kremlin Bicêtre, France, 4Ea4123, Faculty of Pharmacy, Paris-Sud University, Chatenay Malabry, France

496 Pharmacokinetics of Raltegravir 400 vs 800 mg BID With Intermittent Rifampicin Dosed Thrice Weekly
Helen E. Reynolds1, Deirdre Egan2, Laura Else3, Mas Chaponda4, Ales Chrdle5, David J. Back6, Saye H. Kho7
1University of Liverpool, Liverpool, United Kingdom, 2Royal Liverpool University Hospital, Liverpool, United Kingdom

497 Pharmacokinetics of Faldaprevir and Antiretroviral Treatment in Patients With HIV/HCV Coinfection
Jürgen K. Rockstroh1, Marc-Antoine Valantin2, Josep Mallolas3, Massimo Pudl1, Juan Antonio Pineda1, Patrick Ingiliz3, Marina Núñez3, Fengli Huang4, Richard Vinisko5, Douglas Dieterich6
1Department of Medicine I, University of Bonn, Bonn, Germany, 2Service des Maladies Infectieuses et Tropicales, Hopital Pitie-Salpetriere, Paris, France, 3Hospital Clinic-University of Barcelona, Barcelona, Spain, 4Department of Infectious Diseases, AO Ospedale Niguarda Ca’ Granda Milano, Milan, Italy, 5Unit of Infectious Diseases and Microbiology, Hospital Universitario de Vaime, Seville, Spain, 6Medical Center for Infectious Diseases, Berlin, Germany, 7Wake Forest University Health Sciences, Winston-Salem, NC, United States, 8Boehringer Ingelheim Pharmaceutical, Inc, Ridgefield, CT, United States

498 Pharmacokinetic Interactions Between the HCV NS5A Inhibitor MK-8742 and Efavirenz
Wendy Yeh1, William Marshall2, Eric Margini3, Xiaobi Huang1, Yali Zhu1, Susanne Langley1, Patricia James4, Stephen Youngberg5, Joan Burtton1
1Merck, Sharpe and Dohme, Whitehouse Station, NJ, United States, 2Celgene, Lincoln, NE, United States

499 Effect of Faldaprevir On Atazanavir Pharmacokinetics in Patients With HIV/HCV Coinfection
Mark Nelson1, Keikawa Arasteh2, Mamta K. Jain3, Vince Soriano4, Josué Valdez Madruga5, Juvenio Furtado6, Manuel Battegay7, Fengli Huang8, Montserrat Manero9, Douglas Dieterich10
1Chelsea and Westminster Hospital, London, United Kingdom, 2EPIMEED/Vivantes Auguste-Victoria-Klinikum, Berlin, Germany, 3UT Southwestern Medical Center, Dallas, TX, United States, 4Hospital Carlos III, Madrid, Spain, 5Centro de Referencia e Treinamento DST/AIDS, Sao Paulo, Brazil, 6Faculdade de Medicina do ABC and Hospital Helipolis, Sao Paulo, Brazil, 7University Hospital Basel, Basel, Switzerland, 8Boehringer Ingelheim Pharmaceutical, Inc, Ridgefield, CT, United States, 9Boehringer Ingelheim España, Barcelona, Spain, 10Mount Sinai Medical Center, New York, NY, United States

500 No Meaningful PK Interaction Between HCV Protease Inhibitor MK-5172 and Tenofovir or Raltegravir
Wendy W. Ye1, Jain P. Fraser1, Luzelena Caro2, Jennifer Tatlay3, Zifang Guo4, Henry Davis5, Stephen P. Youngberg6, Joan R. Burtton1
1Clinical Pharmacology/Clinical Research, Merck Research Laboratories, Boston, MA, United States, 2Clinical Pharmacology/Clinical Research, Merck Research Laboratories, Upper Gwynedd, PA, United States, 3Celgene, Lincoln, NE, United States

501 Effect of Faldaprevir On Raltegravir Pharmacokinetics in Healthy Volunteers
David Joseph1, Peter Rosa2, Natalia Strekowa3, Armin Schultze4, Jeannette Garcia5, Mabrouk Elgadi6, Fengli Huang7
1Boehringer Ingelheim Pharmaceuticals, Inc, Ridgefield, CT, United States, 2Boehringer Ingelheim Pharma GmbH & Co KG, Biberach, Germany, 3CRS Clinical Research Services Mannheim GmbH, Mannheim, Germany, 4Boehringer Ingelheim (Canada), Ltd, Burlington, ON, Canada

502 No Clinically Relevant Interactions Between Daclatasvir and Cyclosporine or Tacrolimus
Marc Bifano1, Robert Adamczyk2, Carey Hwang1, Hamza Kandoussi3, Alan Marion4, Richard J. Bertz5
1Research and Development, Bristol-Myers Squibb, Hopewell, NJ, United States, 2Research and Development, Bristol-Myers Squibb, Lawrenceville, NJ, United States, 3ICON Development Solutions, Omaha, NE, United States

Session P-H2 Poster Session
Tuesday March 4, 2014, 2:30 pm–4:00 pm Exhibit Hall B
Pharmacogenetics: Drug Disposition To Therapeutics

503 ABC24 3348 T-C SNP Affects Tenofovir Urinary Output in HIV-Positive Patients
Andrea Calcagno, Jessica Cusato, Letizia Marinaro, Marco Simiele, Alice Trentalange, Chiara Montrucchio, Chiara Alcantarini, Antonino D’Avalio, Giovanni Di Perri, Stefano Bonora
Unit of Infectious Diseases, Department of Medical Sciences, University of Torino, Torino, Italy

504 Relative Genetic Contribution To the Pharmacokinetics of Commonly Prescribed Antiretrovirals
Marco S. Siccardi1, Adeniyi Olagunju2,3, Marco Simiele2,3, Antonio D’Avalio2, Andrea Calcagno1, Giovanni Di Perri4, Stefano Bonora5, Andrew Owen4,5
1Department of Molecular and Clinical Pharmacology, University of Liverpool, Liverpool, United Kingdom, 2Faculty of Pharmacy, UAB, Barcelona, Spain, 3Universidad Autonoma de Madrid, Madrid, Spain, 4Department of Medicine, University of Bonn, Bonn, Germany, 5Department of Infectious Diseases, AO Ospedale Niguarda Ca’ Granda Milano, Milan, Italy

505 Leveraging Genomics in HIV Treatment Decisions
Paul A. McLaren1, Margalida Rotger1, Manel Aouri2, Huldrych Günthard3, Calla Marzolfi1, Lauren Decostere4, Amaia Teker5
1The Swiss HIV Cohort, Lausanne, Switzerland, 2The Swiss HIV Cohort, Zurich, Switzerland, 3The Swiss HIV Cohort, Basel, Switzerland

506 Contribution of CYP2A6, UGT2B7, and Other Non-CYP2B6 Polymorphisms To Plasma Efavirenz Exposure
David Haas1, Aweewara Kwaza2, Danielle M. Richardson3, Paxton Baker4, Ioannis Papageorgiou1, Edward P. Acosta5, Gene D. Morris6, Michael Court7,8, the AIDS Clinical Trials Group (ACTG)
1Vanderbilt University, Nashville, TN, United States, 2Brown University, Providence, RI, United States, 3Washington State University, Pullman, WA, United States, 4University of Alabama at Birmingham, Birmingham, AL, United States, 5State University of New York at Buffalo, Buffalo, NY, United States

Session P-H3 Poster Session
Wednesday March 5, 2014, 2:30 pm–4:00 pm Exhibit Hall B
ARV Pharmacokinetics, Drug Interactions, and Pharmacodynamics

507 Rilpivirine With Darunavir/Ritonavir: Pharmacokinetics & Safety in HIV Therapy–Naïve Patients
Aki G. A. Jackson1, Laura J. Else2, Christopher Higgins2, Zeenat Karolia1, Saye Kho3, David Back4, Andrew Murungi5, Emma Devitt6, Anton Pozniak7, Marta Boftto8
1St Stephen’s AIDS Trust, St Stephen’s Centre, Chelsea & Westminster Hospital, London, United Kingdom, 2Department of Molecular and Clinical Pharmacology, University of Liverpool, Liverpool, United Kingdom, 3Infectious Diseases, Jarlsberg UK, High Wycombe, United Kingdom
508 Rilpivirine Pharmacokinetics With/Without Darunavir/r in Adolescents and Young Adults
Marc Foca1, Ram Yoge2, Andrew Wiznia1, Rohan Hazra1, Patrick Jean-Philippe1, Bobbie Graham1, Paula Britto1, Vincent J. Carey1, Jennifer King1, Tim R. Creasy2, for the IMPAACT P1038A team
1Pediatrics, Columbia University Medical Center, New York, NY, United States, 2Pediatrics, Lurie Children’s Hospital of Chicago, Northwestern University Feinberg School of Medicine, Chicago, IL, United States

509 The Cerebrospinal Fluid HIV Risk Score for Assessing Central Nervous System HIV Activity
Edward R. Hammond1, Rosia M. Crum2, Glenn J. Treisman3, Shruti H. Mehta4, David B. Clifford5, David M. Simpson6, Benjamin B. Gelman7, Ronald J. Ellis1, Scott L. Lefetem1, Justin C. McArthur1
1Johns Hopkins University, Baltimore, MD, United States, 2Washington University, St. Louis, MO, United States, 3Ichthy School of Medicine at Mount Sinai, New York, NY, United States, 4University of Texas, Medical Branch, Galveston, TX, United States, 5University of California, San Diego, CA, United States

510 Efavirenz (EFV) 400 Versus 600 mg Daily: Results of the ENCORE Intensive PK Substudy
Laura Dickinson1, Rebekah Puls2, on behalf of ENCORE1 Pharmacokinetics Substudy Group
1Department of Molecular and Clinical Pharmacology, University of Liverpool, Liverpool, United Kingdom, 2University of New South Wales, Sydney, Australia

511 Correlation Between Atazanavir Concentrations, Clinical Covariates and Side Effects
Christina J. P. Gervasoni1, Paola Meraviglia, Simona Landoni, Valeria Cozzi, Agostino Riva, Nitin Charbe, Laurenza Ferraris, Giuliano Rizzardini, Massimo Galli, Dario Cattaneo
1Luigi Sacco University Hospital, Milan, Italy

512 Tenofovir Diphosphate Concentration-Response Relationship for HIV Prevention in Vaginal Tissue
Melanie R. Nicol1, Cindi W. Emerson2, Julie A. Nelson3, Craig Sykes1, Heath MA Prince1, Kristine B. Patterson2, Angela D. M. Kushuba1
1School of Pharmacy, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 2Center for AIDS Research, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 3Microbiology and Immunology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

513 A Pharmacokinetic Drug-Drug Interaction Study Between Raltegravir and Atorvastatin
Maren Blonk1, Michiel van Beek1, Angela Colbers1, Monique Roukens1, Bas Schouwbenen1, David Burger1
1Department of Pharmacy, Radboud University Medical Center, Nijmegen, Netherlands, 2Department of Pharmacology and Toxicology, Radboud University Medical Center, Nijmegen, Netherlands

Suzan E. Cohrs1, Ammeris E. Luque2, Jeong-Gun Park2, Yoninah Cramer2, Francesca Aveleka2, Adriana Weinberg2, Elizabeth Livingston2, Karin L. Klingman2, Barbara Bastow2, Heather Watts3
1Medicine, Northwestern University, Chicago, IL, United States, 2Medicine, University of Rochester Medical Center, Rochester, NY, United States, 3Biostatistics, Statistical and Data Analysis Center, Boston, MA, United States

515 Multi-System Investigation of the Mechanisms for Raltegravir Association With Intestinal Tissue
Darren Michael Moss1, Paul Curley2, Alison Shone3, Marco Siccardi4, Andrew Owen1
1Molecular and Clinical Pharmacology, Translational Medicine, Liverpool, United Kingdom, 2Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

516 Tenofovir DF 150 mg Once Daily in HIV-Infected Adults With Moderate Renal Impairment
Tim R. Creasy5, Anchalee Avihingsanon5, Guttiva Halue5, Prattana Leenarisirak6, Pra-ornsa Suakrakanchana7, Nicole Ngo-Giang-Huong8, Achara Eksaengsiri9, Gonzague Jourdain9, Virat Klinbuaya9, Chureeratana Bowornwatanawong10
5Faculty of Associated Medical Sciences, PHPT/IRD 174, Chiang Mai University, Chiang Mai, Thailand, 6Division of Allergy and Immunology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, 7Virology Research Laboratory, Chiang Mai, Thailand, 8Institut de Recherche pour le Developpement (IRD), Marseille, France, 9The Government Pharmaceutical Organization, Bangkok, Thailand, 10Sanpantong Hospital, Sanpantong, Thailand

517 Tenofovir Concentrations and Prophylactic Effect in a Macaque Model of Rectal SHIV Transmission
Pete L. Anderson1, David V. Giddens2, Lane R. Bushman3, Jia-Hua Zheng1, L. Anthony Guida1, Walid Heneine3, J. Gerardo Garcia-Lerma2
1Pharmaceutical Sciences, University of Colorado Denver, Aurora, CO, United States, 2University of California San Francisco, San Francisco, CA, United States, 3Center for Disease Control and Prevention (CDC), Atlanta, GA, United States

Session P-H4 Poster Session
Thursday March 6, 2014, 2:30 PM-4:00 PM Exhibit Hall B
New Clinical and Preclinical Formulations

518 Optimisation of Intramuscular Sustained Release Nano-Formulations Using In Silico Modelling
Rajith Kumar Reddy Rajoli1, David Back1, Steve Rannard2, Andrew Owen1, Marco Siccardi1
1Department of Clinical & Molecular Pharmacology, University of Liverpool, Liverpool, United Kingdom, 2Pharmaceutical Sciences, University of Nebraska Medical Center, Omaha, NE, United States

519 Macrophage Targeted Nanomedicines for Mycobacterial Infections
Benson Edaga1, Dongwe Guo2, Pavan Pulugija3, Jellyn McMillan4, Ximmin Liu5, Howard Gendelman6, Prabagaran Narayanasamy7
1University of Nebraska Medical Center, Omaha, NE, United States, 2Pharmaceutical Science, University of Nebraska Medical Center, Omaha, NE, United States

520 Fluorescent Magnetic Nanoparticle as Anti-HIV Drug Carrier for Rodent Brain Targeting
Ubal Rai1, Hong Ding1, Sudheesh P. Kanthikeel2, Elena M. Kaftanovskaya3, Andrea Raymond1, Karla Munoz-Caamano4, Madhavan Nair5
1Immunology, Florida International University, Miami, FL, United States, 2Department of Human and Molecular Genetics, Florida International University, Miami, FL, United States

521LB A Novel Anti-HIV Particle Provides Sustained Plasma and Cell Drug Levels in Lymph Nodes in Primates
Jennifer Freeling1, Josef Knollien, Cuiying Shu, Rodney JY Ho2,3
1Pharmaceutics, University of Washington, Seattle, WA, United States, 2Pharmaceutics, University of Washington, Seattle, WA, United States, 3Clinical Pharmacology, Fred Hutchinson Cancer Research Center, Seattle, WA, United States
Preclinical Studies of Novel ART Approaches: Entry

**Nanoviridae**

**TBCAD**

**Kinesis 3 Inhibitor**

**Gang Zhang**

**Prasanta K. Dash**

**Dongwei Guo**

**Jayme L. Wiederin**

**Pawel S. Ciborowski**

**Val S. Goodfellow**

**JoEllen M. McMillan**

**Santhi Gorantla**

**Harris A. Gelbard**

**Howard E. Gendelman**

1 Pharmacology and Experimental Neuroscience, University of Nebraska Medical Center, Omaha, NE, United States, 2California Bio, San Diego, CA, United States, 3University of Rochester Medical Center, Rochester, NY, United States

A Multiple Dose Study ofRaltegravir (RAL) Formulations

Matthew L. Rizk

Rajesh Krishna, Valerie Schulz, Jolanda ten Bruggencate-Broeders, Patrick Larson, Larissa Wening

Merck & Co., Inc., West Point, PA, United States

**In Vivo Effects of Solid Drug Nanoparticle and Conventional Efavirenz On Anxiogenesis in Rodents**

Paul Curley

Marco Giardello, Reilli Liptrott, Philip Martin, Tom McDonald, Marco Siccardi, Juliet McKamics, Steve Rannard, Tim Kirkham, Andrew Owen

1 Molecular and Clinical Pharmacology, University of Liverpool, Liverpool, United Kingdom, 2Chemistry, University of Liverpool, Liverpool, United Kingdom, 3Institute of Psychology, Health and Society, University of Liverpool, Liverpool, United Kingdom

**Atazanavir/Cobicistat Fixed-Dose Combination Is Bioequivalent To the Separate Agents**

Xiaolu Tao

Heather Sevinsky, Reena Wang, Palanikumar Ravindran, Karen Sims, Xiaohui Xu, Navin Jarwala, Richard Bertz

1 Bristol-Myers Squibb, Pennington, NJ, United States, 2Bristol-Myers Squibb, South San Francisco, CA, United States, 3Division of Comparative Pathology, Harvard Medical School, Boston, MA, United States, 4Center for Retrovirus Research, The Ohio State University, Columbus, OH, United States, 5Center for Drug Discovery, Southwestern Research Institute, San Antonio, TX, United States, 6Califia Bio, San Diego, CA, United States, 7High Throughput Screening Center, Southern Research Institute, Birmingham, AL, United States, 8Department of Neurology (Microbiology), Harvard Medical School, Boston, MA, United States

**PF74 Inhibits Multiple HIV Capsid Functions Independent of Host Cyclophilin A and CPSF6**

Stephen R. Yant

Luong Tria, Deb Jini, Rujuta A. Bami, Andrew Mulato, Magdelene Hung, Chien-hung Chou, Randall Halcomb, Tomas Cihlar

1 Biology, Gilead Sciences, Foster City, CA, United States, 2Medicinal Chemistry, Gilead Sciences, Foster City, CA, United States

**Recent Progress in Developing Potent and Broadly Active HIV-1 Maturation Inhibitors**

Emiko Urano

Sherimay D. Ablan, David Martin, Ritu Gaur, Paul W. Keller, Alasdair C. Steven, Theodore Nitz, Carl Wild, Eric O. Freed

1 HIV Drug Resistance Program, NCI-Frederick, Frederick, MD, United States, 2DFH Pharma, Inc, Gaithersburg, MD, United States, 3South Asian University, New Delhi, India, 4National Institute of Arthritis and Musculoskeletal and Skin Diseases/NIH, Bethesda, MD, United States

Session P-11 Poster Session

**Tuesday March 4, 2014, 2:30 pm–4:00 pm**

**Exhibit Hall B**

**Preclinical Studies of Novel ART Approaches: Entry**

**Non-Integrating Lentivirus Delivered CCR5-ZFNs Can Inhibit HIV-1 Infection in Humanized Mice**

Guohua Yi

Jiang-Gi Choi, Preeti Bharaj, Sojan Abraham, Manjunath Swamy, Premlata Shankar

1 Department of Biomedical Sciences, Center of Excellence in Infectious Disease, Texas Tech University Health Sciences Center, El Paso, TX, United States

**Role of Sulfhydryl in Causing Lytic Inactivation of HIV-1 by Env Targeting Peptide Triazole Thios**

Lauren D. Bailey

Caitlin Duffy, Huiyuan Li, Ali Emileit, Arangassery R. Bastian, Irwin Chaiken

1 Biochemistry and Molecular Biology, Drexel University College of Medicine, Philadelphia, PA, United States, 2West Virginia University, Morgantown, WV, United States, 3Dartmouth College, Hanover, NH, United States, 4Biomolecular Engineering, Drexel University College of Medicine, Philadelphia, PA, United States

**eCD4-Ig Is a Highly Potent HIV-1 Entry Inhibitor**

Matthew Gardner

Lisa Kattenhorn, Jessica Chiang, Michael Farzan

1 Department of Infectious Diseases, The Scripps Research Institute, Jupiter, FL, United States, 2Division of Comparative Pathology, Harvard Medical School, Southborough, MA, United States, 3Department of Microbiology and Immunobiology, Harvard Medical School, Boston, MA, United States

**Computational Design of Novel Potent Inhibitors of HIV-1 Entry**

Marina Tuyishime

Simon Cocklin

1 Biochemistry, Drexel College of Medicine, Philadelphia, PA, United States

**Cenicriviroc Achieves High CCR5 Receptor Occupancy at Low Nanomolar Concentrations**

Emilie Jaber

Mary Margaret Byron, Cecilia Shikuma, Helen Jenkins, Eric Lefebvre, Jason D. Barbour

1 University of Hawaii Manoa, Honolulu, HI, United States, 2Tobira Therapeutics, South San Francisco, CA, United States

**Partner-Based Intervention for Adherence To Second-Line ART: A Multinational Trial (ACTG A5234)**

Robert Gross

1 Cancer Immunology and AIDS, Dana Farber Cancer Institute, Boston, MA, United States, 2Department of Pathology, Harvard Medical School, Boston, MA, United States, 3Department of Biologics, College of the Holy Cross, Worcester, MA, United States, 4Department of Infectious Diseases Research, Southern Research Institute, Birmingham, AL, United States, 5High Throughput Screening Center, Southern Research Institute, Birmingham, AL, United States, 6Department of Microbiology, Harvard Medical School, Boston, MA, United States

**Recent Progress in Developing Potent and Broadly Active HIV-1 Maturation Inhibitors**

Emiko Urano

Sherimay D. Ablan, David Martin, Ritu Gaur, Paul W. Keller, Alasdair C. Steven, Theodore Nitz, Carl Wild, Eric O. Freed

1 HIV Drug Resistance Program, NCI-Frederick, Frederick, MD, United States, 2DFH Pharma, Inc, Gaithersburg, MD, United States, 3South Asian University, New Delhi, India, 4National Institute of Arthritis and Musculoskeletal and Skin Diseases/NIH, Bethesda, MD, United States

Session P-1 Poster Session

**Thursday March 6, 2014, 2:30 pm–4:00 pm**

**Exhibit Hall B**

**RCTs in Second-Line ART and Virologic Failure**

**Mortality Among HIV+ Participants Randomized To Omit NRTIs vs. Add NRTIs in OPTIONS (ACTG A5241)**

Karen Tashima

Laura Smeaton, Karin Klingman, Adriana Andrade, Joseph Eron, Carl Fichtenbaum, Rajesh Gandhi, Victoria Johnson, Richard Hauber

1 Medicine, Warren Alpert Medical School of Brown University, Providence, RI, United States, 2Center for Biostatistics in AIDS Research, Boston, MA, United States, 3HIV Research Branch, TRP, HAIDS, NIAID, NIH, Bethesda, MD, United States, 4Medicine, Johns Hopkins University, Baltimore, MD, United States, 5Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 6Medicine, University of Cincinnati, Cincinnati, OH, United States, 7Medicine, Massachusetts General Hospital and Ragon Institute, Boston, MA, United States, 8Medicine, Birmingham VA Medical Center and University of Alabama at Birmingham School of Medicine, Birmingham, AL, United States, 9Medicine, University of California at San Diego, San Diego, CA, United States

**Partner-Based Intervention for Adherence To Second-Line ART: A Multinational Trial (ACTG A5234)**

Robert Gross

1 Cancer Immunology and AIDS, Dana Farber Cancer Institute, Boston, MA, United States, 2Department of Pathology, Harvard Medical School, Boston, MA, United States, 3Department of Biologics, College of the Holy Cross, Worcester, MA, United States, 4Department of Infectious Diseases Research, Southern Research Institute, Birmingham, AL, United States, 5High Throughput Screening Center, Southern Research Institute, Birmingham, AL, United States, 6Department of Microbiology, Harvard Medical School, Boston, MA, United States

**Identification of a Novel HIV-1 Inhibitor Targeting Vif-Dependent Degradation of Human APOBEC3G**

Erez Perry, Andrew Jay Brazer, Ann Sheehy, Vikas Misra, Kottappatty S. Rajendran, Marie K. Markowskii, Lynn Rasmussen, E. Lucile White, Roger G. Prati, Dana Gabuzda

1 Cancer Immunology and AIDS, Dana Farber Cancer Institute, Boston, MA, United States, 2Department of Pathology, Harvard Medical School, Boston, MA, United States, 3Department of Biologics, College of the Holy Cross, Worcester, MA, United States, 4Department of Infectious Diseases Research, Southern Research Institute, Birmingham, AL, United States, 5High Throughput Screening Center, Southern Research Institute, Birmingham, AL, United States, 6Department of Microbiology, Harvard Medical School, Boston, MA, United States

**Drugging HIV Vif as a Rational Approach To Eradication**

Harold C. Smith, Ryan P. Bennett

OyaGen, Inc, Rochester, NY, United States
546 Efficacy of First-Line ARV Regimens: An Exploratory “Target Not Detected” Analysis
Kirsten L. White1, Xuelian Wei1, Lijie Zhong2, Martin S. Rhee1, Marshall W. Fordyce3, Javier Szwarcbarg3, John Mellors2, Michael D. Miller1
1Clinical Virology, Gilead Sciences, Inc, Foster City, CA, United States, 2University of Pittsburgh, Pittsburgh, PA, United States

547 Randomized Comparison of Anthropometric Outcomes On EFV-Based Antiretroviral Therapies
Sineenart Taeraenokul1, Thomas Campbell2, Laura Smeaton2, Amita Gupta2, Nagalingeswaran Kumarsamy3, Karin Klingman4, Isaac Singini5, Javier R. Lana6, Rosie Mingibas7, Michael Hughes8, for the ACTG A5175/PEARS Study Team
1Chiang Mai University, Chiang Mai, Thailand, 2University of Colorado Denver, Aurora, CO, United States, 3Harvard School of Public Health, Boston, MA, United States, 4YRG CARE Medical Centre, Chennai, India, 5NIH, NIAID, DADDS, Bethesda, MD, United States, 6Johns Hopkins University, Baltimore, MD, United States, 7National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, 8University of KwaZulu Natal, Durban, South Africa

548 NEGR1 Genetic Variants and Risk for Virological Failure With Genotypic Resistance in Botswana
Sophie Limou1, Cheryl A. Winkler2, Hermann Bussmann2, 3, Vladimir Neotisky2, 3, Skhulaine Moyo4, Max Essex5, 1Center for Cancer Research, Basic Science Program, Frederick National Laboratory, Leidos Biomedical Research for the National Cancer Institute, Frederick, MD, United States, 2Department of Immunology and Infectious Diseases, Harvard School of Public Health, Boston, MA, United States, 3Botswana-Harvard School of Public Health AIDS Initiative Partnership for HIV Research and Education (BHP), Gaborone, Botswana, 4Vanderbilt Institute for Global Health (VIGH), Vanderbilt University School of Medicine, Division of Infectious Diseases, Nashville, TN, United States

Session P-J3 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM

541 LB Randomized Comparison of Three Second Line ART Regimens in Africa: The 2 Lady/ANRS/EDCTP Study
Sinata Koulla-Shiro1, 2, Laura Ciahf1, Vincent Le Molin, Cheikh Tidiane Nder2, Adrien Sawadogo3, Sabrina Eymard-Duvernay2, Avelin Aghokeng4, Jacques Reynes5, Alexander Calmy6, Eric Delaporte2, on behalf of the ZLADY study group
1Service Maladies Infectieuses, Central Hospital Yaounde, FMSB/UY1, Yaounde, Cameroon, 2Site ANRS Cameroon, Yaounde, Cameroon, 3UM233, IRD, Montpellier, France, 4Service Maladies Infectieuses, Hopital de Fann, CRCHF, Dakar, Senegal, 5CHU Sanou Soum, HOU, Bobo Doulassou, Burkina Faso, 6UM233/IRD, IMP/CREMER, Yaounde, Cameroon, Infectious Diseases, University Hospital Geneva, Geneva, Switzerland

540 Raltegravir Non-Inferior To Standard of Care in SECOND-LINE Therapy Over 96 Weeks
Janaki Amin1, on behalf of the SECOND-LINE study team
The Kirby Institute, University of New South Wales, Sydney, Australia

545 The Oral Exam: A Simple Tool To Identify HIV-Infected Patients in Need of Antiretroviral Therapy
Ashita S. Batavia1, Rode Secours2, Patrice Espinosa1, Marc A. Jean-Juste3, Patrice Severe4, Jean W. Pape2, Daniel W. Fitzgerald2, 1Department of Medicine, New York Presbyterian Hospital, New York, NY, United States, 2The GHESKIO Center, Port-au-Prince, Haiti, 3University of California San Francisco Medical Center, San Francisco, CA, United States

544 LB A Randomized, Placebo-Controlled, Double-Blind Study of VM-1500 in HIV-Naive Patients
Winal Ratanasawat1, Peerawong Weraak1, Robert L. Murphy2, Vadim Bichko3
1Preventive and Social Medicine, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand, 2Northwestern University, Chicago, IL, United States, 3ChemDiv, Inc, San Diego, CA, United States

543 Dolutegravir Regimen Statistically Superior To Tenofir/Emtricitabine/Efavirenz: 96-Wk Data
Sharon Walmsey1, Juan Berenguer2, Marie-Aude Khong-Josses3, Michael Kilby4, Thomas Lutz5, Daniel Podzamczer6, Norma Roth7, Catherine Granier8, Brian Wynne9, Keppa Pappa10
1University Health Network, Toronto, ON, Canada, 2Hospital General Universitario Gregorio Marañón, Madrid, Spain, 3CHUV – Hôpital Delafontaine, Paris, France, 4Medical University of South Carolina, Charleston, SC, United States, 5InfectoBiologikum, Frankfurt, Germany, 6Belgique University Hospital, Brussels, Belgium, 7Infectious disease, CHU Saint-Pierre, Brussels, Belgium, 8Lubumbashi Network & PNMLS, Lubumbashi, Democratic Republic of the Congo, 9CHU Liège, Liège, Belgium

542 First-Line Therapy With LPV/r vs NVP and 2 NRTIs in a Developing Country: W144 of a Randomized Trial
Nathan Cunecke1, Claudia Mwamba2, Kabamba Kabyera3, Serge Matanda4, Dolores Vaira5, Eric Kasconi6, Coca Necsoiu7, David Kadlubek8, Chantal Mitolo9, Joe Ilunga10, Liven Kapend11
1Infectious diseases, CHU Saint-Pierre, Brussels, Belgium, 2Lubumbashi Network & PNMLS, Lubumbashi, Democratic Republic of the Congo, 3CHU Liège, Liège, Belgium

541 LB Paradoxical Impact of Maraviroc/Raltegravir Added To HAART in Acute HIV Infection: ANRS 147 Trial
Antoine Chéret1, 2, Georges Nembot1, Adeline Mériard1, Camille Lécouroux1, Caroline Lascoux2, Isabelle Rayaud2, Jacques Reynes3, Patrick Maillès4, Laurence Meyer5, Christine Rouzioux6
1EA 3620 Virology Laboratory, Université Paris-Descartes Soborbonne Paris Cité, Paris, France, 2Department of Infectious Diseases, DRON Hospital, Tourcoing, France, 3INSERM U1018, APHP Bichat Hospital, Faculty of Medicine Univ Paris-Sud, Le Kremlin-Bicêtre, Paris, France, 4Inserm U1012, Univ Paris-Sud, Paris, France, 5Department of Infectious Diseases, AP-HP, Saint-Louis Hospital, Paris, France, 6Department of Infectious Diseases, La Timone Hospital, Marseille, France, 7Department of Infectious Diseases, Guy de Chauliac Hospital, Montpellier, France, 8Department of Infectious Diseases, Croix Rousse Hospital, Lyon, France, 9INSERM U1018, Univ Paris-Sud, Paris, France

540 RCTs in First-Line ART in Treatment Naive Patients

543 Session P-J2 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM

544 LB Randomised Controlled Trial of a PI Monotherapy Switch Strategy for Long-Term HIV Management
Nicholas Paton1, 2, Wolfgang Stohr3, Alejandro Arenas-Pinto4, David Dunn1, the PIVOT Trial Group
1National University of Singapore, Singapore, Singapore, 2MRC Clinical Trials Unit at UCL, London, United Kingdom

550 LB Simplicity of PI+RTV+FTC/TDF to E/C/F/TDF Maintains HIV Suppression and Is Well Tolerated
Jose Arribas1, Gilles Pialoux2, Joseph Gatell3, Giovanni Di Perri4, Jacques Reyes5, Pablo Tebar3, Thai Nguyen6, Ramin Ebrahim7, Kirsten White8, David Pintkowski9
1Hospital La Paz, Madrid, Spain, 2UPMC, Hôpital Tenon APHP, Paris, France, 3Baylor College of Medicine, Houston, TX, United States, 4University of Turin, School of Medicine, Turin, Italy, 5Gu de Chauliac University Hospital, Montpellier, France, 6University of Pennsylvania, Philadelphia, PA, United States, 7Gilead Sciences, Inc., Foster City, CA, United States

552 LB Effect of Selenium Supplementation On CD4 Depletion in Rwandan HIV Patients: A Randomized Trial
Julius Kamwesiga1, Vincent Mutabazi2, Jean-Claude Tayari1, Heather Fay3, Dugald Seely4, Cara Silva5, Steve Kanters6, Douglas J. McCready7, Don Warren8, Edward Mills9
1Chiang Mai University, Chiang Mai, Thailand, 2University of Colorado Denver, Aurora, CO, United States, 3Harvard School of Public Health, Boston, MA, United States, 4Johns Hopkins University, Baltimore, MD, United States, 5University of Pittsburgh, Pittsburgh, PA, United States, 6University of Washington, Seattle, WA, United States, 7National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, 8San Miguel CRS, Lima, Peru, 9University of KwaZulu Natal, Durban, South Africa

549 LB ART Simplification, Intensification, and Switch Studies

556 HIV Elite Controllers Are Hospitalized More Often Than Persons With Medically Controlled HIV
Trevor A. Crowell1, Kelly A. Gebo2, Joel N. Blankson3, Baigah R. Yehia3, Richard M. Rutstein4, Stephen A. Berry5
1Division of Infectious Diseases & HIV Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, United States, 2Infectious Diseases Institute, Kampala, Uganda, 3Clinical Research Directorate/CMRP, Leidos Biomedical Research, Inc (formerly SAIC-Frederick Inc), Frederick, MD, United States, 4MRC CTU UCL, London, United Kingdom, 5Instituto de Pesquisa Clinica Evandro Chagas, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil

CD4 Cell Count Monitoring Frequency Among HIV+ Persons in New York City
Tuesday March 4, 2014, 2:30 pm–4:00 pm

557 CD4 Cell Count Monitoring Frequency Among HIV+ Persons in New York City (NYC), 2007–2011
Julie E. Myers1, 2, Qiang Xia1, Lucia V. Torian1, Mary K. Irvine1, Blayne H. Cutter1, Graham Harriman1, Kent A. Sepkowitz2, Colin W. Shepard3
1Bureau of HIV/AIDS Prevention and Control, New York City Department of Health and Mental Hygiene, Queens, NY, United States, 2Department of Medicine, Division of Infectious Diseases, Columbia University Medical Center, New York, NY, United States, 3Department of Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY, United States

Failure of Initial HAART in Caribbean, Central and South America
Wednesday March 5, 2014, 2:30 pm–4:00 pm

558 Value of Viremia Copy Years in Deciding Optimal Timing of ART Initiation in Adults With HIV
Ashley Olson1, Sarah Walker2, Amitabh Suthar3, Caroline Sabin1, Heiner Bucher4, Inna Jarrin5, Santiago Moreno5, Santiago Perez-Hoyos5, Kholid Porter2, Deborah Ford6, CASCADE Collaboration in EuroCoord
1MRC CTVU, London, United Kingdom, 2World Health Organization, Geneva, Switzerland, 3University College, London, London, United Kingdom, 4University Hospital Basel, Basel, Switzerland, 5Instituto de Salud Carlos III, Madrid, Spain, 6Instituto Ramón y Cajal de Investigación Sanitaria, Madrid, Spain, 7Universidad Autónoma de Barcelona, Barcelona, Spain

559 Expansion of ART and Progressive Declines in All-Cause Mortality in British Columbia, Canada
Christopher Cheung1, Erin Ding2, Julia Zhu3, Benita Yip4, Lilian Lourenço2, Rolando Barrios5, Julio Montaner1, 4, Robert S. Hogg5, 6, Viviane Lima3, 7, David M. Moore2
1University of British Columbia, Vancouver, BC, Canada, 2BC Centre for Excellence in HIV/AIDS, Vancouver, BC, Canada, 3Simon Fraser University, Burnaby, BC, Canada

560 Higher CD4 at ART Initiation Predicts Greater Long Term Likelihood of CD4 Normalization
Frank J. Palella1, 2, Carl Armson1, Joan S. Chmiel1, John T. Brooks3, Rachel Debes1, Richard Novak1, Bienvenido Yangco2, Kathy Wood2, Marcus Durham1, Kate Buchanan1
1Infectious Diseases, Northwestern University Feinberg School of Medicine, Chicago, IL, United States, 2Cerner Corporation, Vienna, VA, United States, 3Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL, United States, 4Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, GA, United States, 5Infectious Diseases, University of Illinois College of Medicine at Chicago, Chicago, IL, United States, 6Infectious Disease, Infectious Disease Specialists, Tampa, FL, United States, 7HIV Epidemiology Research Team, Centers for Disease Control and Prevention, Atlanta, GA, United States, 8Centers for Disease Control and Prevention, Atlanta, GA, United States

561 Is CD4 Monitoring Needed Among Ugandan Clients Achieving Virologic Response To Treatment?
Steven J. Reynolds1, 2, Joseph Sempa1, Agnes N. Kiragga3, Kevin Newell4, Gertrude Nakigozi1, Larry Changi5, Ronald M. Gallwangi6, Ronald Gray7, Thomas C. Quinn1, 8, David Serwadda9
1Division of Intramural Research, NIAID/NIH, Kampala, Uganda, 2Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, United States, 3Infectious Diseases Institute, Kampala, Uganda, 4Clinical Research Directorate/CMRP, Leidos Biomedical Research, Inc (formerly SAIC-Frederick Inc), Frederick, MD, United States, 5Rakai Health Sciences Program, Kalisizo, Uganda, 6Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, 7Institute of Medical Research, Uganda Research Unit on AIDS, Entebbe, Uganda, 8Baylor College of Medicine Children’s Foundation - Uganda, Mulago, Uganda, 9Joint Clinical Research Centre, Kampala, Uganda, 10Imperial College London, London, United Kingdom, 11Medical Research Council Clinical Trials Unit at University College London, London, United Kingdom

562 Long Term Effects of Treatment Interruptions in Adults and Children
Lindsay C. Thompson1, Deborah Ford2, James Hakim3, Paula Munderi4, Adeoda Kekitiinwa5, Victor Musiime6, Mutswashe Bwakura-Dangarembizi2, Charles F. Gilks4, Diana M. Gibr1, A. Sarah Walker7

556 Measures of ART Adherence Associated With Virological Failure in Rakai, Uganda
Anthony Ndyanabola1, Fred Kamumbi2,3, Gertrude Nakigozi4, David Serrwadda5, Steven J. Reynolds6, Larry Chang7, Mary Grabowski8, Maria Waver9, 1University of Pennsylvania, Philadelphia, PA, United States, 2Johns Hopkins University, Baltimore, MD, United States, 3Massachusetts General Hospital, Boston, MA, United States

557 Measures of Retention in HIV Care Differ in Their Associations With Clinical HIV Outcomes
Baligh R. Yehia1, Peter Reberoi2, Keri Atthoff3, Stephen Gange4, Hasina Samji5, Michael Horberg6, Sonia Napravnik7, Kimberly Kay8, 1University of Pennsylvania, Philadelphia, PA, United States, 2Brigham and Women’s Hospital, Boston, MA, United States, 3British Columbia Centre for Excellence in HIV/AIDS, Vancouver, BC, Canada, 4Kaiser Permanente Mid-Atlantic States, Rockville, MD, United States, 5University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

558 Immune, Virologic and Adherence Measures as Time-Dependent Predictors of Loss To Follow-Up
Seema T. Meloni1, Charlotte Chang2, Doug Hoi Cheung3, Beth Chaplin4, Holly Rawizza5, Oluwatoyin Jolayemi6, Bolanle Banigbe7, Prosper Okonkwo8, Phyllis Kaniki9, 1Immunology & Infectious Diseases, Harvard School of Public Health, Boston, MA, United States, 2Harvard School of Public Health, Cambridge, MA, United States, 3Division of Intraregional Research, National Institute of Allied and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, 4School of Medicine, Johns Hopkins University, Baltimore, MD, United States, 5Johns Hopkins University, Bloomberg School of Public Health, Baltimore, MD, United States

559 Virologic Suppression With Second-Line Therapy: Does the Initial Regimen Matter?
Kevin L. Ard1, Lei Hua2, Camlin Tierney3, Eric S. Daar4, Paul E. Sax5, 1Brigham and Women’s Hospital, Boston, MA, United States, 2Brigham and Women’s Hospital, Boston, MA, United States, 3Harvard School of Public Health, Boston, MA, United States, 4Harbor-UCLA Medical Center, Los Angeles, CA, United States

560 Cumulative Viral Load Predicts All-Cause and AIDS-Related Mortality After Initiation of ART
Michael J. Mugaero1, Andrew O. Westfall2, M. John Giff3, Michael Saag4, Sophie Abgrall5, 1Gerd Falbkenheuer6, Peter Reiss7, Suzanne M. Ingle8, Margaret T. May9, Jonathan A. C. Sterne10, on behalf of ART-CC11, 1Division of Infectious Diseases, Department of Medicine, University of Alabama at Birmingham, Birmingham, AL, United States, 2School of Public Health, Department of Biostatistics, University of Alabama at Birmingham, Birmingham, AL, United States, 3Division of Infectious Diseases, University of Calgary, Calgary, AB, Canada, 4INSERM, UMR S 1136, 5Institut Pierre Louis d’Épidémiologie et de Santé Publique, Paris, France, 6AP-Hôtel Avicenne, Service des Maladies Infectieuses et Tropicales, Bobigny, France, 7Department of Internal Medicine, University of Cologne, Cologne, Germany, 8Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, 9School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom

561 Predictors of Time To Switch To Second Line ART After First Line Failure in Johannesburg South Africa
Julia K. Ro1, Prudence Iwe1, Rebecca Berhanu1, Kate Shearer2, Mhairi Maskew3, Lawrence Long4, Ian Samme5, 1Center for Global Health and Development, Boston University, Boston, MA, United States, 2Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, Clinical HIV Research Unit, Johannesburg, South Africa, 3Right to Care, Johannesburg, South Africa, 4Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, Health Economics and Epidemiology Research Office, Johannesburg, South Africa

562 Dolutegravir in the French Early Access Program in Integrase HIV-2-Resistant Infected Patients
Diane Descampsa, Gilles Meyvair1, Florence Dandona2,3, Roland Tubiana4, Pauline C warp5, Marie-Aude Khuong6, Claudine Douvier7,8, Marina Karmochkine9, Tuna Lukiana10, Sophie Matheron11, 1Virology, APHP-Hôpital Bichat-Claude Bernard, Paris, France, 2IAME UMR 1137 INSERM and Paris Diderot University, Paris, France, 3Pharmacology, APHP-Hôpital Bichat-Claude Bernard, Paris, France, 4Service des Maladies Infectieuses et Tropicales, APHP-Groupe Hospitalier Pitié-Salpétrière, Paris, France, 5Service des Maladies Infectieuses et Tropicales, APHP-Hôpital Saint-Antoine, Paris, France, 6Service des Maladies Infectieuses et Tropicales, Hôpital Delafontaine, Saint-Denis, France, 7Infectious Diseases Department, Necker- Pasteur Infectious Diseases Center, APHP-Necker Hospital, Paris, France, 8Medical Care Center, Necker-Pasteur Infectious Diseases Center, Pasteur Institut, Medical Care Center, Necker-Pasteur Infectious Diseases Center, Paris, France, 9Service d’Immunologie Clinique, APHP-Hôpital européen Georges Pompidou, Paris, France, 10Medical Affairs, ViiV Healthcare, Marly Le ROI, France, 11Service des Maladies Infectieuses et Tropicales, APHP- Hôpital Bichat-Claude Bernard, Paris, France

563 Long Term Outcomes of ART in HIV-2 Infection in Senegal, West Africa
Selly Ba1, Robert A. Smith2, Dana N. Raugi3, Macoumba Toure4, Alasanne Niang5, Ibrahima Salii6, Ousseynou Cisse7, Moussa Seydi8, Papa Sali Sow9, Geoffrey S. Gottlieb10, 1University of Washington, Seattle, WA, United States, 2Europeen Georges Pompidou, Paris, France, 3Microbiology, Medicine and Laboratory Medicine, Medicine, University of Washington, Seattle, WA, United States, 4Region Médicale de Ziguinchor, Ziguinchor, Senegal

564 Favorable Long-Term Outcomes of 2nd-Line ART Despite Drug-Resistant HIV-1 in Sub-Saharan Africa
Tamaras M. S. Boender1, Kim C. E. Siglaff2, Raph L. Hamers3, Cissy Kityo4, Margaret Swaal5, Mariette E. Botes6, Kishor Mandalaya7, Maureen Wellington8, Saleemun Akanmu9, Tobias F. Rinke de Wit10, 1Department of Global Health, Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, 2Department of Global Health, Department of Internal Medicine, Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, 3Joint Clinical Research Centre, Kampala, Uganda, 4Lusaka Trust Hospital, Lusaka, Zambia, 5Muelmed Hospital, Pretoria, South Africa, 6Coast Province General Hospital, Mombasa, Kenya, 7Newlands Clinic, Harare, Zimbabwe, 8Layos University Teaching Hospital, Lagos, Nigeria

565 The HIV Treatment Cascade: Is There More To the Story?
Baligh R. Yehia1, Ailisa J. Stephens2, Allison L. Avgu3, Stephen A. Berry4, Joshua P. Metlay5, Kelly A. Gebo6, 1University of Pennsylvania, Philadelphia, PA, United States, 2Johns Hopkins University, Baltimore, MD, United States, 3Massachusetts General Hospital, Boston, MA, United States

Session P-K4 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM Exhibit Hall B

566 ART: Adherence and Retention

567 Predictors of Time To Switch To Second Line ART After First Line Failure in Johannesburg South Africa

568 Immune, Virologic and Adherence Measures as Time-Dependent Predictors of Loss To Follow-Up

569 Virologic Suppression With Second-Line Therapy: Does the Initial Regimen Matter?

570 Favorable Long-Term Outcomes of 2nd-Line ART Despite Drug-Resistant HIV-1 in Sub-Saharan Africa

Session P-K5 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM Exhibit Hall B

572 Dolutegravir in the French Early Access Program in Integrase HIV-2-Resistant Infected Patients

573 Long Term Outcomes of ART in HIV-2 Infection in Senegal, West Africa

574 Raftegravir-Associated Mutations in HIV-2 Confer Cross-Resistance To Dolutegravir In Vitro

575 Predicting the Extinction of HIV-2 in Guinea-Bissau

Session P-L2 Poster Session

Tuesday March 4, 2014, 2:30 pm–4:00 pm  
Exhibit Hall B

Acquired HIV Drug Resistance

582  High HIV Resistance and Mutation Accrual at Low Viral Loads Upon 2nd-Line Failure in Western Kenya  
Lameck Diero1, Allison DeLong1, Leaann Schreier2, Emmanuel Kembo1, Milcent Orrid1, Mary Rose1, Marissa Reitsma1, Wilfred Emonyi3, Nathan Buziba1, Joseph Hugan3, Rami Kantor4 1Medicine, Moi University, College of Health Sciences, School of Medicine, Eldoret, Kenya, 2Academic Model Providing Access to Healthcare, Eldoret, Kenya, 3Center for Statistical Sciences, Brown University, Providence, RI, United States, 4Medicine, Brown University, Providence, RI, United States

583  Drug Resistance After 2nd-Line Failure Can Be Managed Using WHO-Recommended Regimens in Nigeria  
Nicaise Ndemb1, Rawlings W. Datir1, Danunja Sandra2, David A. M. C. van de Vijver3, Christopher Akoko1, Alash'le G. Abiriku4, William A. Blattner5, Obinna Ogbaru6, Okey C. Nwanwanw7, Patrick Dakun8 1Institute of Human Virology Nigeria, Abuja, Nigeria, 2Virology, Erasmus Medical Center, Rotterdam, Netherlands, 3EPIDEMIOLOGY AND PREVENTION, Institute of Human Virology, Baltimore, MD, United States, 4US Centers for Disease Control and Prevention, Abuja, Nigeria

584  Socio-demographic Determinants of HIV Drug Resistance in British Columbia, Canada  
Chanson J. Brumme1, Melanie Rusch2,3, Keith Chan1, Dmitry Shopin1, Guillaume Colley1, Zabrina L. Brumme1,4, Robert S. Hogg1,4, Julio S. G. Montaner1,5, P. Richard Harrigan1,5 1BC Centre for Excellence in HIV/AIDS, Vancouver, BC, Canada, 2Vancouver Island Health Authority, Victoria, BC, Canada, 3School of Public Health and Social Policy, University of Victoria, Victoria, BC, Canada, 4Faculty of Health Sciences, Simon Fraser University, Burnaby, BC, Canada, 5Division of AIDS, University of British Columbia, Vancouver, BC, Canada

585  Week 144 Resistance Analyses of the Phase 3 EVG/CObI/FTC/ TDF Studies  
Rima Kulkarni, Michael E. Abram, Martin S. Rhe, Marshall W. Fordyce, Javier Szwarcberg, Michael D. Miller, Kirsten L. White, Clinical Virology, Gilead Sciences, Inc., Foster City, CA, United States
588 Emergent and Detectable Proviral DNA Drug Resistance in a Community Treatment Program
Anne Derache1, Hyoungh Shik Shin2, Elizabeth White1, Dennis Israelski1, Jeffrey D. Klauser2, David Katzenstein1, Peninsula AIDS Research Collaboration
1Medical School / Infectious Diseases, Stanford University, Stanford, CA, United States, 2Center for Infectious Disease, National Medical Center, Seoul Korea, Seoul, Republic of Korea, 3David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, United States

589 Acquired Drug-Resistance Mutations and Mortality Among HIV Patients On First-Line ART
Julia W. Wu1, Hui Xiong2, Eric Tchetgen Tchetgen1,3, Lingjie Liao1, Shahin Lockman1,2, Yuhua Ruan1, Victor De Gruttola1, Marc Lipsitch1, 2, George R. Seage1, Yiming Shao2
1Department of Epidemiology, Harvard School of Public Health, Boston, MA, United States, 2Center for AIDS/STD Control and Prevention, Chinese Center for Disease Control and Prevention, Beijing, China, 3Department of Biostatistics, Harvard School of Public Health, Boston, MA, United States, 4Brigham and Women’s Hospital, Boston, MA, United States, 5Department of Immunology and Infectious Diseases, Harvard School of Public Health, Boston, MA, United States

590LB PrEP Exposure and the Risk of Low-Frequency Drug Resistance
Dara A. Lehman1, Jared Bantien2, Connor McCoy3, Julie F. Weiss4, Dylan Peterson1, Connie Celum5, Nelly Mugo4, Connie Celum2, Nelly Mugo4, Julie Overbaugh1, Frederick Matsen3, Pittsburgh, PA, United States, 2Fred Hutchinson Cancer Research Center/University of Washington, United States, 3Human Biology, Fred Hutchinson Cancer Research Center, Seattle, WA, United States, 4Department of Global Health, University of Washington, Seattle, WA, United States, 5Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA, United States, 6Department of Obstetrics and Gynecology, University of Nairobi, Nairobi, Kenya

591 Etravirine/Rilpivirine-Specific Mutations Selected by EFV and Rilpivirine-Associated Resistance in HIV-1 DNA in Suppressed Patients Pretreated by NRTIs
Sebastien Gallien1, Isabelle Charrue2, Marie-Laure NERE1, Nadia Mahjoub3, Nathalie de Castro1, Jean-Pierre Aboulker4, Jean-Michel Molina1, Constance Delaugerre5

592 Detection of NNRTI Resistance Mutations After Interrupting NNRTI-Based Regimens
Valentina Cambiano1, Hannah Castro2, David Chadwick3, Erasmus Smith1, Anna M. Geretti1, David Dunn2, Andrew Phillips1, on behalf of UK HIV Drug Resistance Database & UKHIVA study
1UCL, London, United Kingdom, 2Medical Research Council Clinical Trials Unit, London, United Kingdom, 3University of Newcastle, Newcastle, United Kingdom, 4HPA Heartlands Hospital, Birmingham, United Kingdom, 5University of Liverpool, Liverpool, United Kingdom

593 Detection of NNRTI Resistance Mutations After Interrupting NNRTI-Based Regimens
Valentina Cambiano1, Hannah Castro2, David Chadwick3, Erasmus Smith1, Anna M. Geretti1, David Dunn2, Andrew Phillips1, on behalf of UK HIV Drug Resistance Database & UKHIVA study
1UCL, London, United Kingdom, 2Medical Research Council Clinical Trials Unit, London, United Kingdom, 3University of Newcastle, Newcastle, United Kingdom, 4HPA Heartlands Hospital, Birmingham, United Kingdom, 5University of Liverpool, Liverpool, United Kingdom

594 HIV-1 Resistance Outcomes in Seroconverters From MTN 003 (VOICE)
Urvi M. Parikh1, Krista A. Eskay1, Russell L. Hardesty2, Cliff Kelly2, Craig A. Magaret3, Cindy Moller1, Zvavahera M. Chirenje4, Jeanne Marrazzo5, John W. Mellors1, on behalf of the VOICE Study Team
1Division of Infectious Diseases, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, 2Fried Hutchinson Cancer Research Center/ SCHARP, Seattle, WA, United States, 3Population Sciences, Fried Hutchinson Cancer Research Center/Vaccine and Infectious Disease Institute, Seattle, WA, United States, 4UCSF Collaborative Research Programme in Women’s Health, Harare, Zimbabwe, 5Division of Allergy & Infectious Diseases, University of Washington, Seattle, WA, United States

595 Impact of Raltegravir/Etiravirin Selected Mutations On Dolutegravir Cross-Resistance
Wei Huang1, Arne Frantzelli1, Jeanette M. Whitcomb1, Christos J. Petropoulos2, Monogram Biosciences, South San Francisco, CA, United States

596 N348I in HIV-1 RT Confers Resistance To Etravirine and Rilpivirine But Restricts the Advent of E138K
Veronica Zanchelli1, Hyoung-Ta Xu1, Susan Colby2, Maureen Oliveira1, Yingshan Han1, Yudong Qian1, John Wainberg1, Chen Liang2, McGill AIDS Centre, Lady Davis Institute, Montreal, QC, Canada

597 Impact of Raltegravir/Elvitegravir Selected Mutations On Mechanisms of HIV Drug Resistance
Debra A. Ragland1, Madhavi N.L. Nalam1, Aysegul Ozen1, Yufeng Cai1, Hong Cao1, Celia A. Schiffer2, Biochemistry and Molecular Pharmacology, University of Massachusetts Medical School, Worcester, MA, United States

598LB Two Distinct Mechanisms of Resistance To Allosteric HIV-1 Integrase Inhibitors
Alison Slaughter1, Kellie Jurado1, Lei Feng2, Nanjie Deng1, Nivedita Jena1, Jacques J. Kessl1, James R. Fuchs1, Ronald M. Levy3, Alan Engelmann1, Mamuka Kvaratskhelia1
1Ohio State University, Columbus, OH, United States, 2Harvard University, Boston, MA, United States, 3Temple University, Philadelphia, PA, United States

599 Impact of CD4 Mimetics-Resistant Mutations On Susceptibilities To Anti-env nMabs
Shigeyoshi Harada, Satamatchaya Boonchawalit1, 2, Tetsuo Narumi2, Hirokazu Tamamura, Shouzou Matsushita1, Kazuhiyo Yoshimura1, 2AIDS Research Center, National Institute of Infectious Diseases, Shinjuku, Tokyo, Japan, 3Kumamoto University, Kumamoto, Japan, 4Tokyo Medical and Dental University, Tokyo, Japan

600 M184I and M230I Minority Variants in ART-Naive Patients Are Linked To AP08EBCG/F Activity
Mari Nagouera-Julian1, Alessandro Cozzi-Leffr1, Francesca di Giallonardo2, Rob Schuurman1, Martin Dale1, Sue Aikbern1, Huldryck F. Günthard1, Françoise Brun-Vezinet1, Roger Paredes1, Karin J. Metzner1, CHAIN Minority HIV-1 Variants Working Group
1IrsiCaixa Retrovirology Lab, Badalona, Spain, 2University College, London, United Kingdom, 3Division of Infectious Diseases and Hospital Epidemiology, University Hospital Zurich, Zurich, Switzerland, 4Utrecht Medical Centre, Utrecht, Netherlands, 5Institut für Immunologie und Genetik, Kaiserslautern, Germany, 6Association de Recherche en Virologie et Hematologie, Paris, France

601 Characterising the Complex Mutational Pathways Associated With Maraviroc-Resistant HIV-1
Xiaowei Jiang1, Felix Feyertag2, Conor Meenan1, Simon Travers3, Charles Craig4,5, Mike Westby2, Marilyn Lewis1,6, David L. Robertson2, 1Department of Genetics, University of Cambridge, Cambridge, United Kingdom, 2Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom, 3National University of Ireland Galway, Galway, Ireland, 4South African National Bioinformatics Institute, Belville, South Africa, 5The Research Network, Sandwich, United Kingdom, 6Pfizer R&D, Sandwich, United Kingdom

Session P-L3 Poster Session
Wednesday March 5, 2014, 2:30 PM–4:00 PM
Exhibit Hall B
Mechanisms of HIV Drug Resistance

595 Impact of Raltegravir/Etiravirin Selected Mutations On Dolutegravir Cross-Resistance
Wei Huang1, Arne Frantzelli1, Jeanette M. Whitcomb1, Christos J. Petropoulos2, Monogram Biosciences, South San Francisco, CA, United States

596 N348I in HIV-1 RT Confers Resistance To Etravirine and Rilpivirine But Restricts the Advent of E138K
Veronica Zanchelli1, Hyoung-Ta Xu1, Susan Colby2, Maureen Oliveira1, Yingshan Han1, Yudong Qian1, John Wainberg1, Chen Liang2, McGill AIDS Centre, Lady Davis Institute, Montreal, QC, Canada

597 Analyses of Accessory Mutations in HIV-1 Protease Reveal Interdependent Mechanisms of Resistance
Debra A. Ragland1, Madhavi N.L. Nalam1, Aysegül Ozen1, Yufeng Cai1, Hong Cao1, Celia A. Schiffer2, Biochemistry and Molecular Pharmacology, University of Massachusetts Medical School, Worcester, MA, United States

600 Impact of CD4 Mimetics-Resistant Mutations On Susceptibilities To Anti-env nMabs
Shigeyoshi Harada, Satamatchaya Boonchawalit1, 2, Tetsuo Narumi2, Hirokazu Tamamura, Shouzou Matsushita1, Kazuhiyo Yoshimura1, 2AIDS Research Center, National Institute of Infectious Diseases, Shinjuku, Tokyo, Japan, 3Kumamoto University, Kumamoto, Japan, 4Tokyo Medical and Dental University, Tokyo, Japan

601 Characterising the Complex Mutational Pathways Associated With Maraviroc-Resistant HIV-1
Xiaowei Jiang1, Felix Feyertag2, Conor Meenan1, Simon Travers3, Charles Craig4,5, Mike Westby2, Marilyn Lewis1,6, David L. Robertson2, 1Department of Genetics, University of Cambridge, Cambridge, United Kingdom, 2Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom, 3National University of Ireland Galway, Galway, Ireland, 4South African National Bioinformatics Institute, Belville, South Africa, 5The Research Network, Sandwich, United Kingdom, 6Pfizer R&D, Sandwich, United Kingdom
603 Antiretroviral-Naive and -Treated Patients Can Harbor Viruses in CSF More Resistant Than in Plasma
Cathia Soulie1, Diane Descamps1, Maxime Grude1, Véronique Schneider1, Mary-Anne Trabaud2, Laurence Morand-Joubert2, Constance Delaugerre2, Vincent Calvez3, Philippe Flandre4, Anne-Geneviève Marcellin5, ANRS Resistance AC11 Group

604 Retention and Decay of HIV-1 Drug Resistance Mutations in Proval DNA
Justin De La Cruz6, Saran Vardhanabhutli7, Robert M. Rovner1, Benjamin Pinsky8, Ronald Bosco9, David Kaltenstein10
1Medicine, Infectious Diseases, Stanford University, Stanford, CA, United States, 2Biostatistics, Harvard University, Cambridge, MA, United States, 3Pathology, Stanford University, Stanford, CA, United States

605 Prevalence of Minority Variants To ETR, DRV, and RAL at Baseline in the ANRS 139 TRIO Trial
Charlotte Charpentier1, Lea O. Guinevere1, Christophe Rodriguez1, Benoît Visseau1,2, Catherine Fagard1, Jean-Michel Molina2, Christine Kattama2, Yazdan Yazdani-Rank1, Richard P. Harrigan1, Diane Descamps1,2
1Laboratoire de Virologie, Hôpital Bichat-Claude Bernard, Paris, France, 2IAME-UMR 1137, Université Paris 7, Paris, France, 3BC Centre for Excellence in HIV/AIDS, Vancouver, BC, Canada, 4Virology Laboratory Bichat Hospital, Paris, France, 5INSERM U394, INSERM-UPMC, Paris, France, 6Virology Laboratory Tenon Hospital, Paris, France, 7Virology Laboratory Centre de Biologie Nord Croix Rousse Hospital, Lyon, France, 8U943, Virology Laboratory Saint Antoine Hospital, Paris, France, 9Virology Laboratory Saint Louis Hospital, Paris, France

606 Pan Degenerate Amplification and Adaptation for Highly Sensitive Detection of ARV Drug Resistance
Iain J. MacLeod1,2, Christopher F. Rowley3,4, M. Essex1,2
1Department of Immunology and Infectious Diseases, Harvard School of Public Health, Boston, MA, United States, 2Botsman-Harvard AIDS Institute, Gabonone, Botswana, 3Beth Israel Deaconess Medical Center, Boston, MA, United States

607 Genotypic Tropism Testing of Proval DNA To Guide Maraviroc Initiation in Aviremic Subjects
Federico Garcia1, Eva Poveda2, Maria Angeles Ribas3, Maria Jesus Perez-Elias4, Onofre J Martinez-Madrid4, Jordi Navarro5, Antonio Ocampo6, Felix Gutierrez7, Miguel Garcia-Deltor9, Roger Paredes2, PROTEST Study Group
1Hospital Universitario San Cecilio, Granada, Spain, 2WIBIC-Complejo Hospitalario Universitario de A Coruña, A Coruña, Spain, 3Hospital Son Espases, Palma de Mallorca, Spain, 4Hospital Ramon y Cajal, Madrid, Spain, 5Hospital General Universitario Santa Cruz, Cartagena, Spain, 6Hospital Universitat Vall d’Hebron, Barcelona, Spain, 7Hospital Xeral de Vigo, Vigo, Spain, 8Hospital de Eche, Eixe, Spain, 9Hospital General Universitario de Valencia, Valencia, Spain, 10Hospital Universitat Germans Trias i Pujol, Badalona, Spain

608 Characterization of NNRTI Mutations in HIV-1 RT Using Single Molecule, Real-Time SMRT® Sequencing
Anand Sethuraman1, Michael P. S. Brown1, Colleen Ludka1, Yan Guo1, Ellen E. Paxinos1
1Applications and Collaborations, Pacific Biosciences, Menlo Park, CA, United States, 2Bioinformatics, Pacific Biosciences, Menlo Park, CA, United States

609 Colera RUO Integrase Resistance Assay Performs Well Across Several Subtypes
Carole L. Wallis1, Raquel V. Viana1, Elias Konstantine Halvas2, John W. Mellors3
1Molecular Pathology, Lanceit Laboratories, Johannesburg, South Africa, 2Division of Infectious Diseases, University of Pittsburgh, Pittsburgh, PA, United States

610 Feasibility and Clinical Utility of HIV-1 Genotype Testing in the Setting of Low-Level Viremia
Maria Mercedes Santoro1, Daniele Armeria2, Claudia Alteni2, Lavinia Fabeni2, Domenico Di Pinto2, Federica Fortbici2, Ada Bertoti2,3, Caterina Gorl2, Andrea Antonini2, Carlo Federico Perna4
1University of Rome Tor Vergata, Rome, Italy, 2L Spallanzani Hospital, Rome, Italy, 3University Hospital Tor Vergata, Rome, Italy

611 Tropism Testing by MiSeq is Comparable To 454-Based Methods But Exhibits Contamination Issues
Luke C. Swenson1, Winnie Dong1, Celia K. S. Choi1, Konan K. Woods2, Marjorie Robbins1, Alejandro Gonzalez-Serna2, Aram Karakas, Art Poon1, Chanson J. Brumme1, P Richard Harrigan1
BC Centre for Excellence in HIV/AIDS, Vancouver, BC, Canada

Session P-L6 Poster Session

Thursday March 6, 2014, 2:30 PM–4:00 PM
Exhibit Hall B
Cost Effectiveness Studies of ART and Drug Resistance Testing

612 A Proposed HIV Reference Sample Characterized by Three Next-Generation Sequencing Platforms
Alejandro Gonzalez-Serna1, Chanson J. Brumme1, Winnie Dong1, Eric Calif1, Art F. Y. Poon2, Kelly D. Huber2, Nicolas Sluis-Cremer2, Ellen E. Paxinos1, Luke C. Swenson1, Paul Richard Harrigan1
1British Columbia Centre for Excellence in HIV/AIDS, Vancouver, BC, Canada, 2School of Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, 3Medicine, Division of Infectious Diseases, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, 4Applications and Collaborations, Pacific Biosciences, Menlo Park, CA, United States, 5Department of Medicine, Division of AIDS, Vancouver, BC, Canada

Session P-M1 Poster Session

Tuesday March 4, 2014, 2:30 PM–4:00 PM
Exhibit Hall B
HIV Early Detection: Application of New Assays

615 Application of the Genieus™ HIV-1/2 Supplemental Assay for Detection of Recent HIV Infections
Sheila M. Keating1, Gary Murphy2, Alex Welte2, Rasheda Kasanjone2, David Mathison1, Shelley N. Facente1, Mila Lobedeva1, Michael P. Buschi3, Christopher D. Pilcher4, Consortium for Evaluation of Performance of HIV Incidence Assays (CEPHIA)
1Blood Systems Research Institute, San Francisco, CA, United States, 2University of California San Francisco, San Francisco, CA, United States, 3Public Health England, London, United Kingdom, 4SACEMA, Stellenbosch, South Africa, 5Medicine, University of California San Francisco, San Francisco, CA, United States
619 Evaluation of the Proposed US CDC Algorithm for Detection of Acute HIV Infection in Serial Samples
Leigh Anne Eller1, Mark Manak1, Ashley Shutt1, Rappe Trichavaroj1, Joseph Oundo1, Cornelia Luer4, Fatim Jallow5, Jerome Kim5, Merle Robbins5, Sheila Peel5
1US Military HIV Research Program, Walter Reed Army Institute of Research, Washington, DC, United States, 2Department of Microbiology, University of California, Los Angeles, Los Angeles, CA, United States, 3Department of Microbiology and Parasitology, Hospital Ramón y Cajal, Madrid, Spain, 4Centre National de Référence des Tests VIH, Laboratoire Universitaire, Université Paris Descartes, Paris, France, 5Anova Medical Center, Budapest, Hungary

620 Evaluation of the Hologic Aptima HIV-1 Quant Dx Assay With HIV-1 Subtypes
Mark M. Manak1, Holly Hack2, Tracy Trisic3, Sangeetha Nair4, Andrew Worlock5, Sheila A. Peel5, Jennifer Malia1, Linda Jagodzinski3
1DLDM, US Military HIV Research Program, Silver Spring, MD, United States, 2Hologic, San Diego, CA, United States, 3Center for Disease Control and Prevention, Atlanta, GA, United States, 4Fielding School of Public Health, University of California Los Angeles, Los Angeles, CA, United States, 5Anova Medical Center, Budapest, Hungary

Session P-N1 Poster Session
Tuesday March 4, 2014, 2:30 pm–4:00 pm
Exhibit Hall B
HCV Testing and Epidemiology

628 High Hepatitis C Infection Rate in Birth Cohort Testing of an Urban, Primary Care Clinic Population
Alexander G. Gebo1, Sandeep Mahajan2, Alison P. Daly3, Candice F. Sewell4, Won K. Cho5, Carmella A. Cole5, Dawn A. Fishbein6
1MedStar Health Research Institute, Washington, DC, United States, 2Department of Medicine, Johns Hopkins University, Baltimore, MD, United States, 3Centers for Disease Control and Prevention, Atlanta, GA, United States, 4VA Medical Center, Bronx, NY, United States, 5Health Services Research, Baltimore, MD, United States, 6MedStar Health Research Institute, Washington, DC, United States

629 Prevalence and Risk Factors of Hepatitis C Virus Infection in China’s National Methadone Program
Cynthia X. Shi1,2, Aozhou Wu1, Keming Rou1, Enwu Liu1, Yan Zhao1, Xiaobin Cao1, Changhe Wang1, Wei Luo1, Zunyou Wu1
1National Center for AIDS/STD Control and Prevention, Chinese Center for Disease Control and Prevention, Beijing, China, 2Infectious Disease Clinics, Azienda Ospedaliero-Universitaria Policlinico di Modena, Modena, Italy

Poster Listings
630 The Burden of Hepatitis C Infection in Pennsylvania State Prisons and Implications for Treatment
Madeline Mahowald1, Sarah Larmey1,2, Nicholas Scharff1, Curt Beckwith3, Lynn E. Taylor4, Nick Zaller5, Timothy Flanagan4
1The Warren Alpert Medical School at Brown University, Providence, RI, United States, 2National Drug and Alcohol Research Centre, Sydney, Australia, 3Bureau of Health Care Services, Meachamius, PA, United States, 4Division of Infectious Diseases, The Miriam Hospital, Providence, RI, United States

631 Impact of Rapid Hepatitis C Testing On Receipt of Hepatitis C Results in a Public STD Clinic
Oluwaseun Falade-Nwulia1, Shruti Mehta2, Mark Sulkowski3, Jackline Lasola4, Khalil Ghanem5, Patrick Chau6, David Thomas7
1Division of Infectious Diseases, Johns Hopkins University, Baltimore, MD, United States, 2Baltimore City Health Department, Baltimore, MD, United States, 3Department of Epidemiology, Johns Hopkins University, Baltimore, MD, United States

632 Hepatitis C Antigen Testing: A Reliable Alternative for Diagnosing Acute HCV Infection
Simon George Shaw, Fiona Cresswell, Gary Homer, Mohammed Hassan-ibrahim, Martin Fisher
HIV Medicine, Brighton and Sussex University Hospitals NHS Trust, Brighton, United Kingdom

633 Hepatitis C Virus Incidence in the Amsterdam Cohort Study Among Men Who Have Sex With Men: 1984-2011
Joost W. Vanhoumeringen1,2, Inkee G. Stolte3, Ferrike A. E. Lambers4, Ronald B. Geskus4, Thijs J. W. van de Leat5, Martien W. Borgdrong6, Sylvia M. Bruijn7, Janke Schinkel7, Marie Prins8,9
1Department of Infectious Diseases, Public Health Service, Amsterdam, Netherlands, 2Department of Medical Microbiology, Academic Medical Center, Amsterdam, Netherlands, 3Department of Clinical Epidemiology, Biostatistics and Bioinformatics, Academic Medical Center, Amsterdam, Netherlands, 4Department of Blood-borne Infections, Public Health Service, Amsterdam, Netherlands, 5Department of Internal Medicine, Center for Infectious diseases and Immunology Amsterdam (CINIMA), Academic Medical Center, Amsterdam, Netherlands

640 FIB-4 Outperforms Liver Biopsy in the Assessment of Prognosis in HIV/HCV Coinfection
Juan Berenguer1, Francisco X. Zamora2, Ana Carrero2, Miguel Angel von Wichmann3, José López-Aldeguer4, María J. Téllez5, José Sanz6, Herminia Esteban1, José M. Belkón7, Juan González-García8, and GESIDA 3603 Study Group
1Hospital General Universitario Gregorio Marañón, Madrid, Spain, 2Hospital Universitario La Paz, Madrid, Spain, 3Hospital Donostia, San Sebastián, Spain, 4Hospital La Fe, Valencia, Spain, 5Hospital Clínico San Carlos, Madrid, Spain, 6Hospital Príncipe de Asturias, Alcalá de Henares, Spain, 7Fundación SEIMC GESIDA, Madrid, Spain

641 Sustained Virologic Response and the Risk of Liver Decompensation in HCV and HIV/HCV Patients
Temitope O. Olufade1, Li Wang2, Scott Devine3, Onur Basar4, Vincent Lo Re5
1US Outcomes Research, Merck Sharp & Dohme, North Wales, PA, United States, 2STATinMED Research, Dallas, TX, United States, 3Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, United States

642LB GWAS Reveals New Genetic Associations With Liver Fibrosis Progression
Stephanie Dominguez1,2, Sigrid Le Clerc1, Damien Uveling1, Taoufik Labibi, Maria Winköck1, Ioannis Theodorou1, Laurent Abef1, Yves Levy1,2, Dominique Salmon1, Jean Francois Zagy1
1Clinical Immunology and Infectious disease, Henri Mondor Hospital, Paris, France, 2INSERM U955, Creteil, France, 3Chaire de Bioinformatique, Conservatoire des Arts et Métiers, Paris, France, 4INSERM U987 ISPED, Bordeaux Segalen University, Bordeaux, France, 5INSERM U945, Pierre et Marie Curie University, Paris, France, 6Laboratory of Human Genetics of Infectious Diseases INSERM U896, University Paris Descartes Imagine Institute, Paris, France, 7Infectious and Tropical diseases, Cochin Hospital, Paris, France

643 Incident HCV Infections in the Swiss HIV Cohort Study: Natural History and Treatment Outcomes
Gilles Wandelzer1,2, Janine Rohrbach3,4, Karin Metzner5, Jan Fehr1, Marcel Stöckle1, Matthias Cavassini6, Juan Ambrosioni5, Olivia Keiser4, Hansjakob Furrer2, Nadine Rauch6,7
1Bern University Hospital, Bern, Switzerland, 2University of Bern, Bern, Switzerland, 3University Hospital Zurich, Zurich, Switzerland, 4University Hospital Basel, Basel, Switzerland, 5University Hospital Lausanne, Lausanne, Switzerland, 6University Hospital Geneva, Geneva, Switzerland

644 Is There Long-Term Evidence of Advanced Liver Fibrosis After Acute Hepatitis C in HIV Coinfection?
Christoph Boesecke1, Patrick Inglis2, Mattias Mandorfer3, Carolyne Schwarze-Zander1, Florian Berger1, Marc-Antoine Valantin1, Jan-Christian Wasmuth1, Thomas Reiberger1, Stefan Mauss1, Juergen K. Rockstroh1, and the NEAT study group
1Department of Internal Medicine I, Bonn University Hospital, Bonn, Germany, 2MIB, Berlin, Germany, 3Medical University of Vienna, Vienna, Austria, 4Center for HIV and Hepatogastroenterology, Düsseldorf, Germany, 5Hôpital La Pitié Salpêtrière, AP-HP, Paris, France

645 Hepatic Decompensation in HIV/HBV/HCV Patients and the Impact of HBV Therapy
Temitope O. Olufade1, Li Wang2, Scott Devine3, Onur Basar4, Vincent Lo Re5
1US Outcomes Research, Merck Sharp & Dohme, North Wales, PA, United States, 2STATinMED Research, Dallas, TX, United States, 3Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, United States
646 Short-Term Risk of Decompensation Among HIV/HCV-Coinfected Patients With Significant Fibrosis  
Juan Macias1, Manuel Márquez2, Dolores Merino3, Francisco Tellez4, Antonio Rivero5, Luis Lopez Cortes6, Maria Mancebo7, Juan A. Pineda8  
1Hospital Universitario de Valme, Seville, Spain, 2Hospital Universitario Virgen de la Victoria, Málaga, Spain, 3Hospital Juan Ramón Jiménez, Huelva, Spain, 4Hospital La Línea, La Línea de la Concepción, Spain, 5Hospital Universitario Reina Sofia, Córdoba, Spain, 6Hospital Universitario Virgen del Rocío, Seville, Spain

647 Differential Immune Marker Levels Linked To Liver Fibrosis in HIV/Hepatitis C (HCV) Coinfection  
Nasheed Moquet1, Cynthia Kanagaratnam1, Danuta Radzioch2, Sahar Saeed3, Marina B. Klein4, Canadian Co-infection Cohort  
1Epidemiology, Biostatistics, and Occupational Health, McGill University, Montreal, QC, Canada, 2McGill University, Montreal, QC, Canada

648 Outcome of 215 HCV/HCV-Coinfected Liver Transplant Recipients: A Prospective Multicenter Study  
Jose M. Miro1, Miguel Montijo2, Marino Blanes3, Abradalo Manuel4, Santos del Campo4, Luis Castells5, Antoni Rafecas6, Christian Manzano7, Iñaki Perez1, Antoni Rimonla7, and FIES investigators  
1Hospital Clinic-IDIBAPS, University of Barcelona, Barcelona, Spain, 2Hospital Universitario de Cruces, Bilbao, Spain, 3Infectious Diseases, Hospital la Fe, Valencia, Spain, 4Hospital Doce de Octubre, Madrid, Spain, 5Hospital Universitario Ramon y Cajal, Madrid, Spain, 6Hospital Universitario Vall d'Hebron, Barcelona, Spain, 7Hospital Bellvitge-IDIBELL, University of Barcelona, L'Hospitalet de Llobregat, Spain

649 Liver Fibrosis Progression Among Persons With Recently Acquired HCV Infection  
Adeel A. Butt1,2, Peng Yan1, Vincent Lo Re1, Marina B. Klein1, Matthew B. Goetz1,3, David Leaf1, Matthew S. Freiberg1, Kenneth E. Sherman1  
1University of Pennsylvania, VA Pittsburgh Healthcare System, Pittsburgh, PA, United States, 2Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates, 3University of Pittsburgh, Pittsburgh, PA, United States, 4University of Pennsylvania, Philadelphia, PA, United States, 5McGill University Health Center, Montreal, QC, Canada, 6VA Greater Los Angeles Healthcare System, Los Angeles, CA, United States, 7University of Cincinnati School of Medicine, Cincinnati, OH, United States

650 Predicting Risk of ESDL in HIV/HCV Patients for Individualized HCV Therapy Decisions  
Vincent Lo Re1, Janet P. Tator1, Adeel A. Butt1, Marina B. Klein1, Cynthia Gibert1, David Rimland3, Matthew B. Goetz1, Jay R. Kostman1, Amy C. Justice1, Russell Localio1  
1University of Pennsylvania, Philadelphia, PA, United States, 2VA Connecticut Healthcare System, West Haven, CT, United States, 3University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, 4McGill University Health Centre, Montreal, QC, Canada, 5Washington DC VA Medical Center, Washington, DC, United States, 6Atlanta VA Medical Center, Atlanta, GA, United States, 7VA Greater Los Angeles Healthcare System, Los Angeles, CA, United States

651 Level of Alcohol Use and Advanced Hepatic Fibrosis in HIV-Infected and Uninfected Patients  
JP Tate1,2, JK Lim3,4, KJ Bryant1, CL Gibert5, D. Rimland5, MB Goetz5, MB Klein5, DA Fiellin6, AC Justice7, V. Lo Re1,2,3,4  
1Yale University School of Medicine, New Haven, CT, United States, 2National Institute on Alcohol Abuse and Alcoholism (NIAAA), Washington, DC, United States, 3Georgetown Washington University School of Medicine, Washington, DC, United States, 4Emory School of Medicine, Atlanta, GA, United States, 5David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA, United States, 6Department of Medicine, McGill University, Montreal, QC, Canada, 7University of Pennsylvania School of Medicine, Philadelphia, PA, United States

652 Liver-Related Death in HIV/HCV Cofected Individuals: Who Should Be Targeted for HCV Treatment?  
Daniel Grint1, Lars Peters2, Juergen K. Rockstroh3, Aza Rachmanova4, Igor Karpov5, Massimo Galli5, Pere Domingo6, Ole Kirk7, Jens D. Lundgren8, Amanda Mocroft9  
1University College London, London, United Kingdom, 2Copenhagen HIV Programme, Copenhagen, Denmark, 3University of Bonn, Bonn, Germany, 4Medical Academy of Bolków Hospital, St. Petersburg, Russian Federation, 5Belarus State Medical University, Minsk, Belarus, 6Luigi Sacco Hospital, Milan, Italy, 7Hospital de Sant Pau, Barcelona, Spain

653 Significant Decrease of Liver Fibrosis in HIV-HCV Cofected Patients Treated for HCV Infection  
Marc Arthur Loko1, Camille Gilbert2, Karine Lacombe3, Caroline Lacoux-Combe4, Gilles Pialoux5, Linda Wittkop6, Christine Kattami7, François Dabis8, Dominique Salmon9  
1INSERM, Bordeaux, France, 2Assistance Publique Hôpitaux de Paris, Paris, France

654LB On-Treatment Viral Response To MK-5172/MK-8742 ± RBV for 12 Weeks In HIV/HCV-Cofected Patients  
Mark Sulkowskia1, Josep Malloisa2, Marc Bourliere4, Jan Gerstot5, Oren Shiboleta6, Ronald Nahasa7, Edwin DeJesus8, Melissa Shaughnessyna9, Peggy Hunga10, Barbara Habera10  
1Johns Hopkins University School of Medicine, Baltimore, MD, United States, 2Hospital de Dia, Enfermedades Infecciosas, Barcelona, Spain, 3Service d’hépato-gastroentérologie, Hôpital Saint-Joseph, Marseille, France, 4Department of Infectious Diseases, Rigshospitalet, Copenhagen, Denmark, 5Liver Unit, Department of Gastroenterology, Tel-Aviv Medical Center, Tel Aviv, Israel, 6ID Care, Hillsborough, NJ, United States, 7Orlando Immunology Center, Orlando, FL, United States, 8Merck & Co. Inc., Whitehouse Station, NJ, United States

655 Slow HCV-RNA Decay and Early Resistance Predict the Risk of Failure To TVR/BOC Treatment  
Francesca Caccherinib, Silberstein1, Valeria Cento1, Veila Chiara Di Maio1, Daniele Di Paolob, Sergio Babulideric, Massimo Andreoni1, Giustino Parrutid, Giuliano Rizzardini1, Carlo Federico Pernoe  
1Department of Experimental Medicine and Surgery, University of Rome Tor Vergata, Rome, Italy, 2Hepatology Unit, University Hospital of Rome Tor Vergata, Rome, Italy, 3Infectious Diseases Unit, Department of Clinical and Experimental Medicine, University of Sassari, Sassari, Italy, 4S. Martino Hospital, Genoa, Italy, 5Infectious Diseases Unit, University Hospital of Rome Tor Vergata, Rome, Italy, 6Infectious Diseases Unit, Pescaia General Hospital, Pescaia, Italy, 7Division of Infectious Diseases, Hospital Sacco of Milan, Milan, Italy

656LB Global Origin of HCV NS3 Substitution Q80K That Is Associated With Lower Simeprevir Susceptibility  
Art F. Poon1, Richard H. Liang1, Jeffrey B. Joy1, Thu Nguyen1, Rosemary M. McCloskey1, Mel Krajden2, Julio S. G. Montaner1, P. Richard Harrigan1  
1BC Centre for Excellence in HIV/AIDS, Vancouver, BC, Canada, 2BC Centre for Disease Control, Vancouver, BC, Canada

658 Protease Inhibitors To Treat Hepatitis C in The Swiss HIV Cohort Study: High Efficacy But Low Uptake  
Sebastian Haubitz1, Verena Scherer2, Juan Ambrosi3, Matthias Cavassini1, Marcel Stieckel1, Patrick Schmid1, Laurent Decostder1, Karin Metzner1, Jan Feichtinger1, André Rauch2  
1Division of Infectious Diseases, Bern, Switzerland, 2Division of Infectious Diseases, Zurich, Switzerland, 3Division of Infectious Diseases, Geneva, Switzerland, 4Division of Infectious Diseases, Lausanne, Switzerland, 5Division of Infectious Diseases, Basel, Switzerland, 6Division of Infectious Diseases, St Gallen, Switzerland

659LB Boceprevir for Previously Treated HCV-HIV Cofected Patients: The ANRS-HC27 BocepreviHIV Trial  
Isabelle Poizot-Martin1,2, Eric Bellissant1,3, 4, Philippe Colson5,6, Alain Renault7,8, Lionel Pirioli9, Caroline Solas1, Marc Bourliere1, Rodolphe Garraffo1, Philippe Halfon1, Jean-Michel Molina1,2, and the ANRS HC27 BOCEPREVII Study Group  
1Immuno-Hematological Clinical Unit, Aix Marseille University, APHM Sainte-Marguerite, Marseille, France, 2Insenm U012 (SESSTM), Marseille, France, 3Department of Clinical Pharmacology, Rennes University Hospital, Rennes, France, 4INSERM U 0203 CIC-P Clinical Investigation Centre, Rennes, France, 5Fédération de Microbiologie Hospitalière, Aix Marseille Université, AP-HM Timone, Marseille, France, 6URMITE, UM 63, CNRS 7278, IRD 198, INSERM 1095, Marseille, France, 7Infectious Disease Department, University Hospital, Hôpital du Bocage, Dijon, France, 8Department of Pharmacology and Toxicology, Aix Marseille Univ, APHM Timone, Marseille, France, 9CR02, INSERM U911, Marseille, France, 10Hepatogastroenterology Department, Saint Joseph Hospital, Marseille, France, 11Laboratoire de Pharmacologie, Faculté de Medicine of Nice, Hôpital Pasteur, Nice, France
660 Boceprevir/Telaprevir-Based Therapy in HIV-Infection: Interim Analysis of a Multicenter Cohort
Karim Neumann1, 2, Daniela Munteanu3, 4, Antonio Rivero5, Annette Habr6, Manuel Márquez7, Patrick Ingiliz8, Ignacio de los Santos-Gil2, Thomas Lutz9, Juergen K. Rockstroh1, 2, Daniel Cohen10, Manuel Doroana2, Oksana Chernova3, Jürgen Rockstroh4, Benjamin Go5, Sonia Vibhakar6, Rafael Bárcena7, Carmen Quereda8, Carmen Quereda1, 2
1Institute of Infectious Diseases and Microbiology, Hospital Universitario de Valme, Seville, Spain, 2University of Liverpool, Liverpool, United Kingdom, 3Bohn University Hospital, Bonn, Germany, 4Matei Bals National Institute of Infectious Diseases, Bucharest, Romania, 5Hospital Universitario Reina Sofia, Cordoba, Spain, 6Frankfurt University Hospital, Frankfurt am Main, Germany, 7Hospital Virgen de la Victoria, Malaga, Spain, 8Medical Center for Infectious Diseases, Berlin, Germany, 9Hospital Universitario de la Princesa, Madrid, Spain, 10Infectiologikum, Frankfurt am Main, Germany

661 Favorable Adverse Event Profile of Sofosbuvir/Ribavirin Versus Standard of Care for Hepatitis C
Kerry Townsend1, Shivakumar Narayanan2, Amy Nelson1, Adrian Majid1, Luciano Kapeluszni3, Robert R. Redfield4, Shyamadasanandan Kotttil3, Rohit Talwani5, Anuruloapo Osinrui6, 7
1LIR, NIAID, NIH, Bethesda, MD, United States, 2Institute of Human Virology, Div. of Infectious Diseases, University of Maryland School of Medicine, Baltimore, Maryland, United States

662LBF InF-Free 3 DAA Regimen in HCV Genotype 1-Infected Patients On Methadone or Buprenorphine
Jacob Lalezari1, 2, Greg Sullivan3, Peter Vanunok4, Edward Galen3, 5, Kris V. Kowdley1, Vinod Rustgi2, Humberto Aguilar6, Franco Felizarta7, Daniel Cohen9, Hui Tang8
1Quest Clinical Research, San Francisco, CA, United States, 2Parkway Medical Center, Birmingham, AL, United States, 3Premier Medical Group of the Hudson Valley, NY, United States, 4Institutional Review Board, University of California, San Francisco, California, United States, 5Department of Health Sciences, University of California San Diego Health Sciences, San Diego, CA, United States, 6Infectious Diseases, Hospices Civils de Lyon, Lyon, France, 7Hospital Universite Lyon 1 - HUPL, Lyon, France, 8Centre Hospitalier Intercommunal, Creteil, France, 9Clinical Research Center, LLC, Shreveport, LA, United States, 10Metropolitan Research, Fairfax, VA, United States

663 Telaprevir Treatment of HIV/HCV G1 Patients With Severe Fibrosis: Efficacy Results To Week 16
Andrea Gori1, Manuela Dorona2, Oksana Chernova3, Jurgen Rockstroh3, Denes Bánhelyi4, Colin Bergin5, Gabriella Verucchi6, Andrew Hill7, Blanca Hadacek8, Mark Nelson9
1Division of Infectious Diseases, San Gerardo Hospital, Monza, Italy, 2School of Public Health, University of California at Berkeley, Berkeley, CA, United States, 3Institute of Infectious Medicine, University Hospital Bonn, Bonn, Germany, 4Hôpitaux Universitaires de Strasbourg, Strasbourg Cedex, France, 5Special Populations, Family Health Centers of San Diego, San Diego, CA, United States, 6Infectious Diseases, Hospices Civils de Lyon, Lyon, France, 7Hospital Universite Lyon 1 - HUPL, Lyon, France, 8Infectious Diseases, University of California San Diego Health Sciences, San Diego, CA, United States

664LB Telaprevir Increases Ribavirin Toxicity Through eGFR Decrease in HIV-HCV Coinfected Patients
Laurent Cotte1, 2, Aurélie Barail-Tran3, 4, Corine Vincent5, 6, Isabelle Fournier7, Hugues Aumathre1, Pierre De Truchis4, Isabelle Rosà7, Stéphane Chevaliez8, Jean-Pierre Aboulker9, 10, Jean-Michel Molina11

Session P-N5 Poster Session
Wednesday March 5, 2014, 2:30 PM – 4:00 PM Exhibit Hall B
HCV: The Cascade

669 The Treatment Cascade for People With Chronic Hepatitis C Virus Infection in the United States
Bailigh R. Yehia1, Asher Schrauz2, Craig Umscheid3, Vincent Lo Re4
1University of Pennsylvania, Philadelphia, PA, United States, 2New York University, New York, NY, United States

670 Initial Results of a Community-Based Rapid Hepatitis C Testing and Linkage To Care Program
Christian B. Ramers1, Robert Lewis2, Letty Reyes3, Alexander Kuo4, David L. Wyles5
1Special Populations, Family Health Centers of San Diego, San Diego, CA, United States, 2Hepatology and Liver Transplantation, University of California San Diego Health Sciences, San Diego, CA, United States, 3Infectious Diseases, University of California San Diego Health Sciences, San Diego, CA, United States

671 The CORE HCV Cascade a Decade Later: Looking Ahead To an IFN-Free Era
Oluwoyin M. Adeyemi, Stephens Effinger, Benjamin Go, Sonia Vibhakar, Maureen Gallagher, Deborah Wolny, Beckham Goldberg, Mike Demetria, David Barker, Gregory Huyn

672 The Hepatitis C Cascade of Care Among HIV-Infected Patients Following Diagnosis of HCV Infection
Edward R. Cachay1, Lucas Hill2, David Wyles3, Francesca Torriani4, Bradford Colwell1, Craig Ballard1, William Christopher Mathews1
1Medicine, University of California San Diego, La Jolla, CA, United States, 2Pharmacy, University of California San Diego, La Jolla, CA, United States
Session P–N6 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM  Exhibit Hall B
Acute HCV Infection: Pathogenesis

674 Assessing HCV Acquisition Routes in HIV-Infected MSM Using Single Genome Sequencing–A Pilot Study
Daniel S. Frier1, Andrew H. Talal2, Kristen M. Markes3, Wouter O. van Seggelen1, Andrea D. Branch1, Shirish Huprikar1, Shuwy Wang1, George M. Shaw1, Hui Li1
1Infectious Diseases, Mount Sinai School of Medicine, New York, NY, United States
2Gastroenterology, University of Buffalo School of Medicine, Buffalo, Buffalo, NY, United States
3Infectious Diseases, Weill Cornell Medical College, New York, NY, United States

675 Higher Risk of Sexually Acquired HCV Infection in MSM With Wide HIV Transmission Bottleneck
Roger D. Kouyos1, Andri Rauch1, Dominique Braun1, Sabine Yerly1, Jürg Boill1, Thomas Klimkait1, Vincent Aubert1, Bruno Ledergerber1, Huldrych Günthard1
1The Swiss HIV Cohort Study (SHCS)
2University Hospital Zurich, University of Zurich, Zurich, Switzerland
3Inserisipalt Bern, Bern, Switzerland
4University of Geneva, Geneva, Switzerland
5University of Zurich, Zurich, Switzerland
6University of Basel, Basel, Switzerland
7University of Lausanne, Lausanne, Switzerland

676 Seminal HCV RNA Level May Mirror Dynamics of Plasma HCV RNA in HIV-Positive Men With Acute HCV
Daniel Bradshaw1, Francois Lamoun2, Beth Catlett2, Tanya L. Applegate2, John Mcallister2, Gregory J. Dore2, Gail Matthews1, Mark Danta1
1Kirby Institute, University of New South Wales, Sydney, Australia
2St Vincent's Hospital, Sydney, Australia
3Faculty of Medicine, University of New South Wales, Sydney, Australia

677 HCV Viral Load Kinetics During Acute Hepatitis C In HIV-Infected Patients: A Model-Based Analysis
Romain Ragoumet1, Christoph Boesecke1, Marguerite Guiguet2, Karine Lacombe1, 2, Jeremy Guex1, Jürgen K. Rockstroh1, Yazdan Yazdanghah1, 2, Sylvie Deuffic-Burban1, 2
1INSERM U1337, Paris, France
2Department of Internal Medicine I, Bonn University Hospital, Bonn, Germany
3INSERM U943, Paris, France
4INSERM UMR S 707, Paris, France
5Service des Maladies Infectieuses et Tropicales, Hôpital Bichat Claude Bernard, Paris, France
6INSERM U945, Lille, France

Session P–N7 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM  Exhibit Hall B
HCV Infection and Cellular and Humoral Immune Responses

678 Impaired CD8+ T Cell IL-7 Activity in HCV Infection: Implications for HIV–HCV Co-Infection
Stephanie C. Burke1, 2, Lorna Carrasco-Medina1, Curtis L. Cooper1, 2, Angela M. Crawley1, 2
1Department of Biochemistry, Microbiology and Immunology, University of Ottawa, Ottawa, ON, Canada
2Ottawa Hospital Research Institute, Ottawa, ON, Canada
3Department of Epidemiology and Community Medicine, University of Ottawa, Ottawa, ON, Canada

679 HCV and GBV-C NS5A Proteins Inhibit TCR-Mediated Activation of Human CD4+ T Cells
Nirja Bhattarai, Bennett E. Thompson, James H. McLinden, Jinhua Xiang, Jack T. Stapleton
University of Iowa and Iowa City VA, Iowa City, IA, United States

680 Impact of HCV Coinfection On T-Cell Dynamics in Long-Term HIV Suppressors Under CART
Olivia Zaege1, Sylvia Bregliogon1, Carla E. Cano1, Véronique Obry-Raguett1, Corinne Nicoline-Brune1, Catherine Tamale1, 2, Françoise Dignat-George2, Isabelle Poizot-Martin1, 3
1Immuno-Hematological Clinical Unit, Aix Marseille University, APH, Sainte Marguerite Hospital, Marseille, France
2Service d’Hématologie et de Biologie Vasculaire, Aix Marseille University, APH, Conception Hospital, Marseille, France
3Fédération de Microbiologie Hospitalière, Aix Marseille University, APH, Timone Hospital, Marseille, France
4URMITE CNRS-IRDUM 6236, Marseille, France
5Inserm U912 (SSSIM), Marseille, France

Session P–N8 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM  Exhibit Hall B
HCV-Related Outcomes: Cardiac and Non-Liver

681 CD3+CD56+ Natural Killer-Like T Cells in HIV(+) Patients With Acute Hepatitis C
Pavlos Kokorelis1, 2, Benjamin Krämer1, 2, Christoph Boesecke1, 2, Esther Voigt1, 2, Patrick Ingiliz1, 2, Andreas Glässner1, 2, Ulrich Spengler1, 2, Jürgen K. Rockstroh1, 2, Jacob Nattermann1
1Internal Medicine I, University of Bonn, Bonn, Germany
2German Center for Infection Research (DZIF), Bonn, Germany
3Internal Medicine I, Praxis am Ebertplatz, Cologne, Germany
4Medical Center for Infectious Diseases (MID), Berlin, Germany

682 The Effect of Hepatitis C Virus (HCV) Clearance On Macrophage Activation in HIV/HCV Coinfection
Kara W. Chew1, Lei Hua2, Debika Bhattacharya1, Adeel A. Butt1, 2, 3, Matthew Lewis1, Raymond T. Chung1, 4, Janet W. Anders5, Judith S. Currier1
1David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, United States
2Harvard School of Public Health, Boston, MA, United States
3University of Pittsburgh School of Medicine, Pittsburgh, PA, United States
4Harvard Medical School, Boston, MA, United States

683 HIV Patients Develop High Levels of Broadly Neutralizing Antibodies Against Hepatitis C Virus
Quentin Lepilliez1, 2, 3, Catherine Faivreau1, Laura Heydmann1, Christanne Moog1, 2, 3, David Rey1, Olivier Lambert1, Nicolas Meyer4, 5, Heidi Barth6, 7, Françoise Stoll-Keller1, 2, 3, Samira Fafi-Kremer1, 2, 3, 4
1Institut de Virologie, FMTS, Hôpitaux Universitaires de Strasbourg, Strasbourg, France
2INSERM, U1110, Université de Strasbourg, Strasbourg, France
3HIV Care Center, Hôpitaux Universitaires de Strasbourg, Strasbourg, France
4Internal Medicine and Infectious Diseases, Hôpital Bichet, INSERM, 1012, Université Paris-Sud, Paris, France
5Biostatistics, Hôpitaux Universitaires de Strasbourg, Strasbourg, France
6Service de Médecine, Université de Strasbourg, France
7Institut de Virologie, FMTS, Hôpitaux Universitaires de Strasbourg, Strasbourg, France

684 Activation and Senescence Markers in HCV-Infected Patients On PegIFN/RBV/Telaprevir Tritherapy
Isabelle Pellegrin1, Céline Cognet1, Pascale Trimoulet1, Juliette Faucher1, Julien Vergnol1, Wassil Merrouche2, Jean-Luc Taupin1, Linda Wittkop1, Jean-FrançoisMoreau1, Victor de Ledinghen1, 2
1immunology, Bordeaux Hospital, Bordeaux, France

5HIV Department, World Health Organization, Geneva, Switzerland,  
6Department of Dermatology, University of California at San Francisco, San Francisco, CA, United States

710 Randomized Trial of Protease Inhibitor-Based Antiretroviral Therapy for Kaposi Sarcoma in Africa

Jeffrey Martin, Miriam Laker-Oketta, Victoria Walusansa, Jackson Orem, John Bennett, Adrienne Mocellin, Toby Maurer, Peter Hunt, Andrew Kambangu

1University of California San Francisco, San Francisco, CA, United States,  
2Infectious Diseases Institute, Kampala, Uganda,  
3Uganda Cancer Institute, Kampala, Uganda,  
4Uganda Virus Research Institute, Entebbe, Uganda
711 Kaposis Sarcoma in the Era of Combination Antiretroviral Therapy
Natascha Wyss, Matthias Egger, Julia Bohlius, Malignancy Working Group for COHERE in EuroCoord
Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland

712 Vitamin D Insufficiency in AIDS-Associated Kaposis Sarcoma in Zimbabwe
Kristine M. Erlanson, Ivy Gutza, Suzanne Fiorillo, Buxton Ndemera, Robert T. Schooley, Lovenmore Gwanzura, Margaret Book, Thomas B. Campbell

- University of Colorado Anschutz Medical Campus, Aurora, CO, United States
- Department of Medicine, University of Zimbabwe College of Health Sciences, Harare, Zimbabwe
- Infectious Diseases, University of California San Diego, San Diego, CA, United States
- Department of Medical Laboratory Sciences, University of Zimbabwe College of Health Sciences, Harare, Zimbabwe

713 Primary Effusion Lymphoma and HIV Infection: 51 Patients From a Single Institution
Stephanie Guillet, Laurence Gerard, Veronique Meilgini, Felix Agbalika, Wendy Cuccini, Lionel Galicier, Eric Okserenheder

- Clinical Immunology, Saint-Louis Hospital, Paris, France
- EA3963, Universite Paris Diderot, Sorbonne Paris Cité, Paris, France
- Pathology, Saint-Louis Hospital, Paris, France
- Hematology Laboratory, Saint-Louis Hospital, Paris, France

714 Indoleamine 2, 3-Dioxygenase (IDO) Activity as a Determinant of Kaposis Sarcoma in Africa
Helen Byakwaga, Peter W. Hunt, Miriam Laker-Okteta, David V. Glidden, Yong Huang, Mwebesa Mwebesa, Victoria Walusansa, David R. Bangsberg, Edward Mtibede, Jeffrey N. Martin

- University of California San Francisco, San Francisco, CA, United States
- Mbarara University of Science and Technology, Mbarara, Uganda
- Infectious Diseases Institute, Kampala, Uganda
- Uganda Cancer Institute, Kampala, Uganda
- Harvard Medical School, Massachusetts General Hospital, Center for Global Health, Boston, MA, United States

Session P-05 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM Exhibit Hall B
Cervical Cancer, HPV, and HPV Vaccine

715 Epidemiology and Dynamics of HPV Infection in Romanian Women Infected With HIV in Early Childhood
Sanjay R. Mehta, Lumi Ene, Cristina Voina, Claudia Stefanescu, Diana Sima, Dan Duclecsu

- Medicine, University of California San Diego, La Jolla, CA, United States
- Dr. Victor Babes Hospital for Infectious and Tropical Diseases, Bucharest, Romania
- Titu Maiorescu University, Bucharest, Romania

716 Baseline Data of a Phase 3 Trial of the Quadrivalent HPV Vaccine in HIV+ Males and Females: ACGT 5298
Ross Cranston, Ming Yang, Pawel Paczuski, Michelle Cepeodes, Elizabeth Chiao, Jennifer Webster-Cyrilique, Catherine Godfrey, Timothy Wilkin

- University of Pittsburgh, Pittsburgh, PA, United States
- Harvard University, Cambridge, MA, United States
- New York University School of Medicine, New York, NY, United States
- Houston VA Medical Center, Houston, TX, United States
- University of North Carolina at Chapel Hill, Chapel Hill, NC, United States
- DAIDS, NIAID, NIH, Bethesda, MD, United States
- Weill Cornell Medical College, New York, NY, United States

717 Cervical Abnormalities in HIV-Infected South African Women With High Screening and Referral Rates
Ingrid T. Katz, Alex A. Wright, Tamaryn L. Crankshaw, Janet Giddy, Sean Mould, Lisa M. Butler

- Medicine, Brigham and Women’s Hospital, Boston, MA, United States
- Harvard Medical School, Boston, MA, United States
- Dana Farber Cancer Center, Boston, MA, United States
- McCord Hospital, Durban, South Africa
- Health Economics and HIV/AIDS Research Division, Durban, South Africa
- University of Cape Town, Cape Town, South Africa
- Gynaecology and Obstetrics, R. K. Kahn Hospital, Chatsworth, South Africa
- Boston Children’s Hospital, Boston, MA, United States

Session P-06 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM Exhibit Hall B
Anal Cancer and HPV

718 Prevalence of Anal Dysplasia in HIV-Infected Women From Johannesberg, South Africa
Bridgeott Goeieman, Cynthia Firthhaber, Pamela Michelow, Avril Swarts, Jennifer S. Smith, Timothy Wilkin

- University of Witwatersrand, Johannesburg, South Africa
- Right to Care, Johannesburg, South Africa
- National Health Laboratory Services, Johannesberg, South Africa
- University of North Carolina, Chapel Hill, NC, United States
- Weill Cornell Medical College, New York, NY, United States

719 Mucosal and Systemic Immune Responses in HIV/HPV Co-infected Males
Laura Corni, Camilla Tincati, Giusi Maria Bellisti, Alessandro Pandolfo, Javier Sanchez Martinez, Veronica Rainone, Marco Rovati, Daria Trabattoni, Antonella d’Arminio Montforte, Giulia Marchetti

- Department of Health Sciences, Clinic of Infectious Diseases, San Paolo Hospital, Milan, Italy
- Departments of Biomedical and Clinical Sciences ‘L. Sacco’ and of Pathophysiology and Transplantation, University of Milan, Milan, Italy
- Department of Health Sciences, Surgery Chair, ‘San Paolo Hospital,’ University of Milan, Milan, Italy

720 Natural History of HIV-Related Anal Dysplasia: A Multi-State Modeling Analysis
Wolleaw W. Agmaa, Edward R. Cachay, Christopher Jackson, Wm. Christopher Matthews

- Internal Medicine, University of California San Diego, La Jolla, CA, United States
- Public Health, Medical Research Council Biostatistics Unit, Cambridge, United Kingdom

721 Antiretroviral Therapy as Protector Factor of Anal Dysplasia in HIV-infected MSM
Carmen Hidalgo Tenorio, Concepcion Gil Anguita, Jessica Ramirez Taboada, Juan Gabriel Martinez Cara, Javier Esquivias, Pablo Palma, Mar Rivero, Rosario Javier Martinez, Miguel Angel Lopez Ruz, Juan Pasqua Llamo

- Infectious Diseases Unit, University Hospital Virgen de las Nieves, Granada, Spain
- Gastroenterology Service, University Hospital Virgen de las Nieves, Granada, Spain
- Pathology Service, University Hospital Virgen de las Nieves, Granada, Spain
- General Surgery Service, University Hospital Virgen de las Nieves, Granada, Spain

722 HPV16-Specific T-Cell Responses and Spontaneous Regression of Anal Intraepithelial Neoplasia
Winnie Y. W. Tong, Kelsee Shepherd, Fengyi Jin, John Zaunders, Richard J. Hillman, Andrew E. Grulich, Anthony Kelleher, Andrew Carr

- Centre for Applied Medical Research, St Vincent’s Hospital, Darlinghurst, Australia, Australia
- The Kirby Institute, Sydney, NSW, Australia

Session P-P1 Poster Session
Tuesday March 4, 2014, 2:30 PM–4:00 PM Exhibit Hall B
Heart Failure, Cardiac Steatosis, and HIV

723 Elevated NT-proBNP Levels Predict Mortality in HIV-infected Women
Matthew R. Gingo, Kidane Ghebrehawariat, Jong-Hyeon Jeong, Yanxia Chu, Quanwei Yang, Lorrie Lucht, David Hanna, Jason Lazaar, Mark Gladwin, Yingze Zhang, Alison Morris

- University of Pittsburgh, Pittsburgh, PA, United States
- Albert Einstein College of Medicine and Montefiore Medical Center, Bronx, NY, United States
- SUNY Downstate Medical Center, Brooklyn, NY, United States
- University of Pittsburgh, Pittsburgh, PA, United States

724 Cardiac Steatosis Increased in HIV: Related To Gender, Visceral Fat and ARV Exposure
Julia B. Purdy, Chia-Hing Liu, Sabrina Mangat, Horacio Duarte, Diana Thorat, Nancyanne Schmidt, Jamie Hur, Christopher T. Sibley, David A. Blumberg, Colleen Hadigan

- Critical Care Medicine, National Institutes of Health, Bethesda, MD, United States
- Diagnostic Radiology Department, National Institutes of Health, United States
725 ST2 and GDF-15 Are Associated With Structural Heart Disease and Mortality in HIV
Eric Secemsky1, Rebecca Scherzer2, Elaine Nitta2, Alan Wu3, David Lange4, Steven Deeks5, Jeffrey Martin6, James Snider7, Peter Ganz8, Priscilla Hiser9
1UCSF, San Francisco, CA, United States, 2University of California San Francisco, San Francisco, CA, United States

726 Depression and HIV Are Risk Factors for Incident Heart Failure Among Veterans
Jessica R. White1, Chung-Chou H. Chang2, Adeel A. Butt3, Hilary A. Tindle4, Maria C. Rodriguez Barradas5, 6, David Rimbland7, David Leaf8, Matthew Budoff9, 10, Amy C. Justice11, 12, Matthew S. Freiberg13
1University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA, United States, 2University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, 3Veterans Affairs Pittsburgh Healthcare System, Pittsburgh, PA, United States, 4Baylor College of Medicine, Houston, TX, United States, 5Emory University School of Medicine, Atlanta, GA, United States, 6Atlanta veteran Affairs Medical center, Atlanta, GA, United States, 7David Geffen School of Medicine, Los Angeles, CA, United States, 8Veteran Affairs Greater Los Angeles Health Care System, Los Angeles, CA, United States, 9Harbor-UCLA Medical Center, Los Angeles, CA, United States, 10Los Angeles Biomedical Research Institute, Los Angeles, CA, United States, 11Veteran Affairs Connecticut Healthcare System, West Haven, CT, United States, 12Yale University School of Medicine, New Haven, CT, United States

Session P-P3 Poster Session
Tuesday March 4, 2014, 2:30 pm–4:00 pm Exhibit Hall B

727 Impact of Low CD4 Count and HIV Persistence On Endothelial Function in Patients With Low Plasma RNA
Amanda Schnell Heringer1, Hiroyu Hatano1, Peter W. Hunt2, Yuaner Wu3, Yifei Ma4, Rebecca Scherzer5, 6, Jeffrey N. Martin7, 8, Peter Ganz9, Steven G. Deeks10, Priscilla Y. Hiser10
1Division of Cardiology, San Francisco General Hospital, University of California San Francisco, San Francisco, CA, United States, 2Positive Health Program, University of California San Francisco, San Francisco, CA, United States, 3Division of Adolescent Medicine, University of California San Francisco, San Francisco, CA, United States, 4Veterans Administration Medical Center, University of California San Francisco, San Francisco, CA, United States, 5Veterans Administration Medical Center, San Francisco, CA, United States, 6Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA, United States

728 Carotid Distensibility and Immune Activation in HIV-Infected Patients Without Coronary Calcium
Chris T. Longenecker1, 2, Ying Jiang1, Sara Debanne3, Grace A. McComsey1, 2
1Case Western Reserve University, Cleveland, OH, United States, 2University Hospitals Case Medical Center, Cleveland, OH, United States

729 Microvascular Disease in Controllers Is Mediated by HIV DNA and Immune Dysfunction
Hiroyu Hatano1, Yifei Ma2, Rebecca Scherzer3, 4, Yuaner Wu2, Elaine Nitta2, Kara Harwil5, Elizabeth Sinclair6, Michael P. Busch7, 8, Steven G. Deeks9, Priscilla Y. Hiser10
1Medicine, University of California San Francisco, San Francisco, CA, United States, 2Pediatrics, University of California San Francisco, San Francisco, CA, United States, 3San Francisco Veterans Affairs Medical Center, San Francisco, CA, United States, 4Laboratory Medicine, University of California San Francisco, San Francisco, CA, United States, 5Blood Systems Research Institute, San Francisco, CA, United States

730 Monocyte But Not Cellular Activation Is Associated With Coronary Atherosclerosis in the MACS
Eric S. Daar1, Wendy S. Post2, Annie T. Darklay2, Peter W. Hunt3, Todd T. Brown4, Rebecca McKibben5, Beth Jamieson6, Matthew J. Budoff7, Mallory D. Witt8
1Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA, United States, 2Johns Hopkins University, Baltimore, MD, United States, 3University of California, San Francisco, San Francisco, CA, United States, 4Veteran Affairs School of Medicine at UCLA, Los Angeles, CA, United States

731 The J-Curve in HIV: Better Cardiovascular-Disease-Free Survival With Moderate Alcohol Intake
Gilles Wandel1, 2, David Kraus3, Jan Fehr4, Anna Conen5, Alexander Calmy6, Christina Onias4, Manuel Battegay5, Patrick Schmidt5, Enos Benasoni5
1Swiss HIV Cohort Study, 2University of Bern, Bern, Switzerland, 3Bern University Hospital, Bern, Switzerland, 4University Hospital Zurich, Zurich, Switzerland, 5Cantonal Hospital St. Gallen, St. Gallen, Switzerland, 6University Hospital Geneva, Geneva, Switzerland, 7University Hospital Lausanne, Lausanne, Switzerland, 8University Hospital Basel, Basel, Switzerland, 9Regional Hospital Lugano, Lugano, Switzerland

732 Soluble CD14 and D-Dimer Are Associated With Smoking and Heavy Alcohol Use in HIV-Infected Adults
Patricia A. Cloe1, John Hammer2, Erna M. Koigi3, Nur Oreni4, Pragna Patel5, Christopher W. Kahler6
1Center for Alcohol & Addiction Studies, Brown University, Providence, RI, United States, 2Memorial Sloan Kettering Cancer Center, New York, NY, United States, 3University of Minnesota Medical School, Minneapolis, MN, United States, 4Denver Infectious Disease Consultants, Denver, CO, United States, 5Veteran Affairs Connecticut Healthcare System, West Haven, CT, United States, 6Veteran Affairs Medical Center, San Francisco, CA, United States

733 Antiviral Therapy and Smoking Associated With Coronary Vessel Thickening in HIV-Infected Youth
Aylin Unsal1, Khaled Z. Abd-Elmoneim2, Sarah Eshera3, Julia B. Purdy4, Rohan Hazra4, Colleen Hadigan5, Ahmed M. Gharbi6
1National Institute of Allergy and Infectious Disease, National Institutes of Health, Bethesda, MD, United States, 2National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD, United States, 3Critical Care Medicine, National Institutes of Health, Bethesda, MD, United States, 4National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD, United States

Session P-P4 Poster Session
Wednesday March 5, 2014, 2:30 pm–4:00 pm Exhibit Hall B

734 HIV Infection and the Risk of Cardiovascular Disease in Women
Julie A. Womack1, Chung-Chou H. Chang2, Kaku A. Armbrt3, Kathleen Mcginnis4, Matthew B. Goetz5, 6, Cynthia L. Gilbert7, 8, Sheldon T. Brown9, 10, Albert L. Warner11, Amy C. Justice12, 13, Matthew S. Freiberg12, 13, for the VACS Project Team
1School of Nursing, Yale University, West Haven, CT, United States, 2University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, 3University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA, United States, 4Veterans Affairs Connecticut Healthcare System, West Haven, CT, United States, 5VA Greater Los Angeles Health Care System, Los Angeles, CA, United States, 6Veteran Affairs Affairs Health Care System, West Haven, CT, United States, 7VA Los Angeles Health Care System, Los Angeles, CA, United States, 8VA Greater Los Angeles Health Care System, Los Angeles, CA, United States, 9VA Medical Center, Washington, DC, United States, 10George Washington University School of Medicine, Washington, DC, United States, 11James J. Peters VA Medical Center, Bronx, NY, United States, 12Mount Sinai School of Medicine, New York, NY, United States, 13VA Medical Center, New Haven, CT, United States

735 Depression Predicts Incident Myocardial Infarction in HIV+ Veterans: Veterans Aging Cohort Study
Tasneem Kambaty1, Jesse C. Stewart2, Samir K. Gupta3, Chung-Chou H. Chang2, Adeel A. Butt4, Cynthia L. Gilbert5, Hilary A. Tindie6, Heidi Crane7, Roger Bedimo8, Matthew S. Freiberg9, on behalf of the VACS project team
HIV Infection, Cardiovascular Risk Factor Profile, and Risk for Acute Myocardial Infarction
Anne-Lise Paasche1, Joyce Chang2, Kaku Armah3, Matthew B. Goetz4, Adel A. Butt5, Maria C. Rodriguez-Barradas6, David Rimland7, Sheldon T. Brown8, Amy C. Justice9, Matthew J. Silverberg10, the WACS Project Team
Internal Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, Biostatistics, University of Pittsburgh School of Public Health, Pittsburgh, PA, United States, Epidemiology, University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA, United States, Veterans Affairs Greater Los Angeles Health Care System and David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, United States, University of Pittsburgh School of Medicine and VA Pittsburgh Healthcare System, Pittsburgh, PA, United States, Medicine, Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates, Infectious Diseases Section, Michael E. DeBakey Veterans Affairs Medical Center, Pittsburgh, PA, United States, Medicine, Baylor College of Medicine, Houston, TX, United States, Division of Infectious Diseases, VA Medical Center, Atlanta, GA, United States, Emory University School of Medicine, Atlanta, GA, United States, James J. Peters Veterans Affairs Medical Center, Bronx, NY, United States, Mount Sinai School of Medicine, New York, NY, United States, VA Connecticut Healthcare System, West Haven, CT, United States, Yale University School of Medicine and Public Health, New Haven, CT, United States

No Difference in Incidence of Myocardial Infarction for HIV+ and HIV- Individuals in Recent Years
Daniel B. Klein1, Wendy A. Leyden2, Chun R. Chao3, Michael A. Horberg4, William J. Towne5, Leo B. Hurley6, Charles P. Quesenberry6, Michael J. Silverberg7
1Kaiser Permanente Northern California, Hayward, CA, United States, 2Kaiser Permanente Northern California, Oakland, CA, United States, Kaiser Permanente Southern California, Pasadena, CA, United States, Kaiser Permanente Mid-Atlantic States, Rockville, MD, United States, Kaiser Permanente Southern California, Los Angeles, CA, United States

MACE Incidence Among HIV- and Non-HIV-Infected Patients in a Clinical Care Cohort
Virginia A. Triant1, Susan Regan, Steven Grinspoon2
Massachusetts General Hospital, Boston, MA, United States

Lower CD4 Count and Higher Viral Load Are Associated With Increased Risk of Myocardial Infarction
1University of Washington, Seattle, WA, United States, 2University of Alabama at Birmingham, Birmingham, AL, United States, 3University of California, San Diego, San Diego, CA, United States, 4Johns Hopkins University, Baltimore, MD, United States, 5University of North Carolina, Chapel Hill, NC, United States, 6University of California, San Francisco, San Francisco, CA, United States

Long-Term Effects of Nitrate Inhalants On Cardiovascular and Renal Outcomes in the MACS Cohort
Alex Holman, Anupriya Dutta, Dana Gubauda
Dana-Farber Cancer Institute, Boston, MA, United States

HIV Infection and Immunodeficiency as Risk Factors for Ischemic Stroke
Julia L. Marcus1, Wendy A. Leyden2, Chun R. Chao3, Felicia C. Chow4, Michael A. Horberg5, Leo B. Hurley6, Daniel B. Klein7, Charles P. Quesenberry7, William J. Towne8, Michael J. Silverberg9
1Kaiser Permanente Northern California, Oakland, CA, United States, Kaiser Permanente Southern California, Pasadena, CA, United States, University of California San Francisco, San Francisco, CA, United States, Kaiser Permanente Mid-Atlantic States, Rockville, MD, United States, Kaiser Permanente Northern California, Hayward, CA, United States, Kaiser Permanente Southern California, Los Angeles, CA, United States

Antiretroviral Therapy Is Associated With Significant Changes in Plasma Lipidome
Janine M. Trevilliant4, Gerard Wong5, Rebekah Puls6, Kathy Petroumenos6, Sean Emery7, Natalie Mellett8, Peter J. Meikle9, Jennifer F. Hoy2
1Infectious Diseases, Alfred Health, Melbourne, Australia, 2Department of Infectious Diseases, Monash University, Melbourne, Australia, 3Metabolomics, Baker IDI Heart and Diabetes Institute, Melbourne, Australia, 4The Kirby Institute, Sydney, Australia
Session P–P6 Poster Session

Thursday March 6, 2014, 2:30 PM–4:00 PM Exhibit Hall B

Statins and ARV Effects in HIV

750 Rosuvastatin Lowers Oxidative LDL in HIV-Infected Persons On Antiretroviral Therapy: SATURN-HIV

corriynn O. Hileman1,2, Richard D. Semba, Randy Turner3, Danielle E. Labbatto1,4, Norma J. Storrer4,1, Grace A. McComsey4,1

1Case Western Reserve University School of Medicine, Cleveland, OH, United States, 2MetroHealth Medical Center, Cleveland, OH, United States, 3Wilmer Eye Institute, Johns Hopkins University School of Medicine, Baltimore, MD, United States, 4University Hospitals Case Medical Center, Cleveland, OH, United States

751LB After 52 Weeks, Pitavastatin Is Superior To Pravastatin for LDL-C Lowering in Patients With HIV

craig A. Sponseller1, Judith Aborg1, INTREPID Team

1Medical Affairs, Kowa Pharmaceuticals America, Inc., Montgomery, AL, United States

752 Endothelial Progenitor Cells Increase in Older HIV-Infected Patients Receiving Telmisartan

Jordan E. Lake, Theodoros Kelesidios, Diana H. Liao, Judith S. Currier, Otto O. Yang

University of California Los Angeles, Los Angeles, CA, United States

Session P–Q1 Poster Session

Tuesday March 4, 2014, 2:30 PM–4:00 PM Exhibit Hall D

Biomarkers and Non-AIDS Events

753 Incidence of CD4/CD8 Ratio Normalization and Its Role in the Onset of Non-AIDS-Related Events

Cristina Musiani1,Patrizia Lorenzin1, Alessandro Cozzi-Levi2, Giuseppe Lapadula1, Giulia Marchetti1, Emmanuele Nicastri2, Antonella Cingolani6, Emanuele Nicastri2, Antonella Cingolani6, Miriam Lichtner1, Andrea Antonini1, Antonella d’Arminio Monforte5, for the ICONA Foundation Study Group

1University of Modena and Reggio Emilia, Modena, Italy, 2Infectious Diseases, University of Milan, Milan, Italy, 3Positive Health Program, Department of Medicine, San Francisco General Hospital, University of California, San Francisco, CA, United States, 4University Hospitals Case Medical Center, Cleveland, OH, United States, 5University Hospitals Case Medical Center, Cleveland, OH, United States

754 Longitudinal Changes in Free Testosterone Among Older HIV-Infected and HIV-Uninfected Men

Laurence Slama1,2, Lisa P. Jacobson1, Xiaohong Li1, Frank J. Paletta1, Joseph B. Margolick1, Lawrence Kingsley5, Dorothy Wiley6, Gilles Païoloux1, Adrian Dobbs1, Todd T. Brown7

1Infectious Diseases, Tenon Hospital, Paris, France, 2Infectious Diseases, Northwestern University, Feinberg School of Medicine, Chicago, IL, United States, 3Epidemiology, Johns Hopkins University, Baltimore, MD, United States, 4Infectious Diseases, Johns Hopkins University, Baltimore, MD, United States, 5Infectious Diseases, University of Pittsburgh, Pittsburgh, PA, United States, 6School of Nursing, University of California, Los Angeles, CA, United States, 7School of Medicine, Johns Hopkins University, Baltimore, MD, United States

755 Inflammatory Biomarkers in Chronic HIV Disease Predominantly Associate With Monocyte Activation

Eleanor M. P. Wilson1, Amitr Singh1, Kathy Huppler Huijilek1, Keith Henry2,3, Ken Lichtenstein1, Pragna Patel1, John T. Brooks4, Irini Sereti5, Jason V. Baker1,3

1Lab of Immunoregulation, NIAID, NIH, Bethesda, MD, United States, 2University of Minnesota, Minneapolis, MN, United States, 3Hennepin County Medical Center, Minneapolis, MN, United States, 4National Jewish Health, Denver, CO, United States, 5CDC, Atlanta, GA, United States

756 Extrinsic Pathway Coagulation Factors Are Associated With Mortality During Treated HIV Disease

Jason V. Baker1, Kathleen Brunnmet-Ziedins2, Jacqueline Neuhaus3, James D. Neaton4, Russell P. Tracy3, INSIGHT SMART and ESPRIT Study Groups

1Infectious Diseases, University of Minnesota, Minneapolis, MN, United States, 2Biochemistry, University of Vermont, Burlington, VT, United States, 3Biostatistics, University of Minnesota, Minneapolis, MN, United States

757 Correlates of Inflammatory Markers After One Year of Suppressive Antiretroviral Treatment (ART)

Surupi Krishna1, Ronald J. Bosch4, Benigno Rodriguez2, Peter W. Hunt4, Cara Wilson3, Steven G. Deeks6, Michael M. Lederman2, Alan L. Landay3, Allan R. Tenorio1

1Harvard School of Public Health, Center for Biostatistics in AIDS Research, Boston, MA, United States, 2Division of Infectious Diseases and HIV Medicine, Case Western Reserve University School of Medicine, Cleveland, OH, United States, 3Positive Health Program, Department of Medicine, San Francisco General Hospital, University of California, San Francisco, CA, United States, 4Division of Infectious Diseases, University of Colorado Hospital, Denver, CO, United States, 5Department of Immunology and Microbiology, Rush University Medical Center, Chicago, IL, United States, 6Department of Medicine, Rush University Medical Center, Chicago, IL, United States

758 Prof12Alia Polymorphism Is Associated With Metabolic Disturbance in HIV/HCV Coinfected Patients

Pilar García-Broncano1, Juan Berenguer1,2, Amanda Fernández-Rodriguez3, Daniel Pineda-Tenor1, María J. Jiménez-Sousa1, Mónica García-Alvarez1, Teresa Aldán Echevarría1,2, Juan Carlos López1, Dariella Micheloud4, Salvador Resino5

1Unidad de Infección Viral e Inmunidad, Centro Nacional de Microbiología, Instituto de Salud Carlos III, Majadahonda, Spain, 2Unidad de Enfermedades Infecciosas/HIV, Hospital General Universitario “Gregorio Marañón”, Madrid, Spain, 3Instituto de Investigación Sanitaria Gregorio Marañón (ISGSM), Madrid, Spain, 4Servicio de Medicina Interna, Hospital General Universitario “Gregorio Marañón”, Madrid, Spain, 5Unidad de Infección Viral e Inmunidad, Centro Nacional de Microbiología, Instituto de Salud Carlos III, Universitario Majadahonda, Spain

759 Predictors of Incident Hypertension in HIV-Positive Adults Over 24 Months On ART in South Africa

Alana T. Brennan1,2, Matthew P. Fox1,2, Mhari Maskew1, Ian Sanne2,3, Prudence Ivey1, Julia Rohr1,2, Lawrence Long1, Sydney Rosen1,2

1Center for Global Health & Development, Boston University, Boston, MA, United States, 2Division of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, Health Economics and Epidemiology Research Office, Johannesburg, South Africa, 3Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, Clinical HIV Research Unit, Johannesburg, South Africa

Session P–Q2 Poster Session

Tuesday March 4, 2014, 2:30 PM–4:00 PM Exhibit Hall D

Frailty: Physical Function and Telomers

762 Frailty, Inflammation and Mortality Among Aging HIV-Infected and At-Risk Injection Drug Users

Daman A. Piggott, Ravi Varadhan, Shruni H. Mehta, Todd T. Brown, Sean X. Leng, Gregory D. Kirk

Johns Hopkins University, Baltimore, MD, United States

763 Brisk Walking Improves Inflammatory Markers in cART-Treated Patients

Valeria Longo1, Matteo Bonato2, Simona Bossolasco1, Laura Galli1, Andrea Caumo1, Gaetare Pavli1, Adriano Lazzarini1, Giampiero Merati1, Antonio La Torre1, Paola Cirne1

1Infectious Diseases, San Raffaele Scientific Institute, Milano, Italy, 2Biomedical Sciences for Health, Università degli Studi di Milano, Milano, Italy, 3Pathophysiology and Transplantation Department, Università degli Studi di Milano, Milano, Italy

764 Cell-Mediated CMV Responses in HIV-Infected Persons With Impaired Physical Function

Kristine M. Erlandson, Amanda A. Althouse, Rick Rapaport, Brent E. Palmer, Cara C. Wilson, Samantha McWhinnie, Thomas B. Campbell

University of Colorado Anschutz Medical Campus, Aurora, CO, United States
765 Presence of the Immune Risk Phenotype and Telomere Shortening Among HIV Treated Patients
Patricia Ndumbi, Julian Faltz, Jason Szabo, Orin Rosengren, Christos M. Tsoukas
Immune Deficiency Treatment Centre, McGill University Health Centre, Montreal, QC, Canada

766 Geriatric Syndromes Are Common Among Older HIV-Infected Adults
Meredith Greene1,2, Victor Valcour1,1, Yinghui Mao1,4, Ken Covinsky1,7, Joy Mudanbhia1, Monica Mattes1, Harry Lampiris1,7, Jeffrey Martin1, Steven Deeks1
1Medicine–Geriatrics, University of California San Francisco, San Francisco, CA, United States, 2San Francisco VA Medical Center, San Francisco, CA, United States, 3Neurology, University of California San Francisco, San Francisco, CA, United States, 4Obstetrics and Gynecology, University of California San Francisco, San Francisco, CA, United States, 5Medicine–HIV/AIDS, University of California San Francisco, San Francisco, CA, United States, 6University of Central Florida College of Medicine, Orlando, FL, United States, 7Medicine–Infectious Diseases, University of California San Francisco, San Francisco, CA, United States, 8Epidemiology & Biostatistics, University of California San Francisco, San Francisco, CA, United States

767 Physical Function Impairment On Quality of Life Among Persons Aging With HIV Infection
Kristine M. Erlanson, Amanda A. Althouse, Catherine M. Jankowski, Samantha Mathhlineny, Wendy M. Koehl, Thomas B. Campbell
University of Colorado Anschutz Medical Campus, Aurora, CO, United States

Session P-03 Poster Session
Tuesday March 4, 2014, 2:30 pm–4:00 pm Exhibit Hall D
Diabetes and Insulin Resistance

768 IL-6, hsCRP, and the Development of Type 2 Diabetes Among HIV Positive Patients Taking ART
Claude L. Béténé, A Dooko
School of Public Health, University of Minnesota, St Paul, MN, United States

769 HbA1c Is A Poor Predictor of Fasting Glycemia in HIV-Infected Men With Low CD4 Count, High MCV and MCH
Laurence Slama1,2, Frank J. Paletta1, Alison G. Abraham3, Xihong Li4, Corinne Vigouroux5,6, Gilles Pialoux1, Lawrence Kingsley4, Jordan E. Lake5, Todd T. Brown6
1Infectious Diseases, Tenon Hospital, Paris, France, 2Infectious Diseases, Feinberg School of Medicine, Northwestern University, Chicago, IL, United States, 3Epidemiology, Johns Hopkins University, Baltimore, MD, United States, 4Biochimie et Hormonologie, Tenon Hospital, Paris, France, 5UPMC Paris 6, UMR S 5938, Paris, France, 6University of Pittsburgh, Pittsburgh, PA, United States, 7Infectious Diseases, University of California Los Angeles, Los Angeles, CA, United States, 8Endocrinology and Metabolism, Johns Hopkins University, Baltimore, MD, United States

770 Triglycerides/HDL Ratio and Risk of Developing Diabetes Mellitus During Antiretroviral Therapy
Nicola Squillaci1, Patrizia Lorenzini2, Giuseppe Lapadula3, Alessandro Cozzi-Lepri4, Stefano Rusconi5, Massimo Puoti6, Antonella Castagnelli7, Andrea Antonini1, Andrea Gori1, Antonella d’Arminio Monforte1, for the ICONA Foundation Study Group
1Infectious Disease Unit, San Gerardo Hospital, University of Milano-Bicocca, Monza, Italy, 2Lazzaro Spallanzani National Institute for Infectious Diseases, IRCCS, Rome, Italy, 3Research Department of Infection and Population Health, University College London, London, United Kingdom, 4Department of Biomedical and Clinical Science Luigi Sacco, Infectious Diseases, University of Milan, Milan, Italy, 5Infectious Disease Unit, Niguarda Ca Granda Hospital, Milan, Italy, 6Department of Infectious Diseases, San Raffaele Scientific Institute, University Vita-Salute San Raffaele, Milan, Italy, 7San Paolo Hospital, University of Milan, Milan, Italy

771 Measuring Physical Activity and its Impact On Insulin Resistance in MACS Men
Anne K. Monroe1, Todd T. Brown2, Christopher Cox1, Dorothy Wiley3, Frank Paletta1, Lawrence Kingsley4, Michael Plankey5
1Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, United States, 2Epidemiology, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, United States, 3UCCLA School of Nursing, Los Angeles, CA, United States, 4Medicine, Feinberg School of Medicine, Northwestern University, Chicago, IL, United States, 5Department of Infectious Diseases and Microbiology, School of Public Health, University of Pittsburgh, PA, United States, 6Medicine, Georgetown University School of Medicine, Washington, DC, United States

772 Impact of Randomized Antiretroviral Therapy (ART) Initiation On Glucose Metabolism: ACTG A5224s
Kristine M. Erlanson1, Douglas Kitch1, Paul E. Sax1, Eric D. Saar1, Camlin Tierney2, Kathleen M. Melbourne3, Belinda Hu4, Grace A. McConsey4, 1University of Colorado Anschutz Medical Campus, Aurora, CO, United States, 2Harvard School of Public Health, Boston, MA, United States, 3Brigham and Women’s Hospital, Boston, MA, United States, 4Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA, United States, 5Bileal Sciences, Foster City, CA, United States, 6VHA Healthcare Research Triangle, NC, United States, 7Case Western Reserve University, Cleveland, OH, United States

Session P-04 Poster Session
Wednesday March 5, 2014, 2:30 pm–4:00 pm Exhibit Hall D
Lung Disease and HIV

773 HIV Infection Increases Risk of Acute Exacerbations of COPD
Allison A. Lambert, Gregory D. Kirk, Jacques Astemborski, Shriuti H. Mehta, M. Bradley Drummond
Johns Hopkins University, Baltimore, MD, United States

774 Association of HIV Infection and Immune Activation With Decline in Lung Function
Kristina Crothers1, Carla V. Rodriguez2, Cheryl Wongtrakool3, Guy Sao Hoo4, Joon Kim5, Sheldon T. Brown2, David Rimland6, Maria C. Rodriguez-Barradas7, Matthew B. Goetz8, Amy C. Justice3
1Department of Medicine, University of Washington, Seattle, WA, United States, 2Department of Medicine, Atlanta Veterans Affairs Medical Center and Emory University, Atlanta, GA, United States, 3Department of Medicine, West Los Angeles Veterans Affairs Medical Center and David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, CA, United States, 4Department of Medicine, James J. Peters Bronx Veterans Affairs Medical Center and and Icahn School of Medicine at Mt Sinai, New York, NY, United States, 5Department of Medicine, Michael E. DeBakey Veterans Affairs Medical Center and Baylor College of Medicine, Houston, TX, United States, 6Department of Medicine, Veterans Affairs Connecticut Healthcare System and Yale University, New Haven, CT, United States

775 HIV Infection and Related Biomarkers Are Independent Risk Factors for Radiographic Emphysema
Engl F. Attia1, Matthew B. Goetz2, Maria C. Rodriguez-Barradas5, David Rimland6, Sheldon T. Brown2, Guy Sao Hoo4, Joon Kim5, Cheryl Wongtrakool3, Kathleen Akgun1, Kristina Crothers2
1Medicine, University of Washington, Seattle, WA, United States, 2Medicine, West Los Angeles Veterans Affairs Medical Center and David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, CA, United States, 3Medicine, Michael E. DeBakey Veterans Affairs Medical Center and Baylor College of Medicine, Houston, TX, United States, 4Medicine, Atlanta Veterans Affairs Medical Center and Emory University, Atlanta, GA, United States, 5Medicine, James J. Peters Veterans Affairs Medical Center and Icahn School of Medicine at Mt Sinai, Bronx and NYC, NY, United States, 6Medicine, West Haven Veterans Affairs Medical Center and Yale University, West Haven, CT, United States

776 Factors Associated With Chronic Obstructive Pulmonary Disease in a High Risk HIV-Infected Cohort
Alain Maksimov1, Maurice Hayot2, Sabrina Eymard-Duvernay3, Francois Raffi4, Laurence Thirard1, Fabrice Bonnet1, Pierre Tattevin1, Sophie Abgrall5, Jacques Revel1, Vincent Le Moing, ANRS EP48 HIV CHEST Study Team
1Infectious and Tropical Diseases Department, University Hospital Bordeaux, INSERM U897, Bordeaux, France, 2Department of Biomedical and Clinical Science Luigi Sacco, Infectious Diseases, University of Milan, Milan, Italy, 3University Hospital Bordeaux, INSERM U897, Bordeaux, France, 4Infectious and Tropical Diseases Department, Nantes University Hospital, Nantes, France, 5Tours University Hospital, Tours, France, 6Internal Medicine and Infectious Diseases Department, University Hospital Bordeaux, INSERM U8697, Bordeaux, France, 7Infectious Diseases and ICU, Pontchaillou University Hospital, Rennes, France, 8INSERM, UMR S 1136 at the Institut Pierre Louis d’Épidémiologie et de Santé Publique, Paris, France, 9AP-HP, Hôpital Avicenne, Service des Maladies Infectieuses et Tropicales, Bobigny, France
Session P-05 Poster Session
Wednesday March 5, 2014, 2:30 pm—4:00 pm
Exhibit Hall D

Bone Disease: Osteopenia, Fracture Risk, and Osteoarthritis

777 Minimal Change in Bone Density and No Association With HIV Factors Over 12 Months in HIV-Infected Men
Amanda Samarawickrama1, Sophie Jose2, Caroline Sabin3, Karen Walker-Bone3, Martin Fisher4, Yvonne Gilbee5
1Clinical Investigation and Research Unit, Brighton and Sussex Medical School, Brighton, United Kingdom, 2Research Department of Infection and Population Health, University College London, London, United Kingdom, 3MRCLifecourse Epidemiology Unit, University of Southampton, Southampton, United Kingdom, 4Department of Infection and Immunity, Brighton and Sussex Medical School, Brighton, United Kingdom, 5Department of HIV and Sexual Health, Brighton and Sussex University Hospitals, Brighton, United Kingdom

778 New Fracture Risk and FRAX 10-Year Probability of Fracture in HIV-Infected Adults
Linda A. Battalora, Kate Buchacz, Carl Armon, Edgar T. Overson, John Hammer, Pragna Patel, Joan Chmiel, Kathy Wood, John T. Brooks, Benjamin Young
1Colorado School of Mines, Golden, CO, United States, 2Centers for Disease Control and Prevention, Atlanta, GA, United States, 3Cerner Corporation, Vienna, VA, United States, 4University of Alabama School of Medicine, Birmingham, AL, United States, 5Denver Infectious Disease Consultants, Denver, CO, United States, 6Feinberg School of Medicine, Northwestern University, Chicago, IL, United States, 7International Association of Providers of AIDS Care, Washington, DC, United States

779LB Bone Density Changes After Antiretroviral Initiation With Protease Inhibitors or Raltegravir
Todd Brown1, Carlee Moser2, Judith Currier3, Heather Ribaudo4, Jennifer Rothenberg5, Michael Dubie1, Robert Murphy2, James Stein3, Grace McComsey1
1Johns Hopkins University, Baltimore, MD, United States, 2Harvard University, Boston, MA, United States, 3UCLA, Los Angeles, CA, United States, 4Social & Scientific Systems, Silver Spring, MD, United States, 5University of Southern California, Los Angeles, CA, United States, 6Northwestern University, Chicago, IL, United States, 7University of Wisconsin, Madison, WI, United States, 8Case Western Reserve University, Cleveland, OH, United States

780 Hand Osteoarthritis, a Joint Disorder Frequent and More Severe in HIV-1 Patients: METAFLIB-OA Study
Anne-Laurence Tomi1, Jeremy Sellam1, Karine Lacombe2, Manuela Sebire3, Caroline Rey-Jouvin2, Anne-Laurence Miquel2, Emmanuel Maheu1, Francis Berenbaum1, Pierre-Marie Girard3, Jean-Luc Meynard4

781 Low Bone Mineral Density Is Associated With Increased Risk of Incident Fracture in HIV+ Adults
Linda A. Battalora1, Kate Buchacz2, Carl Armon2, Edgar T. Overt0n3, John Hammer4, Pragna Patel5, Joan S. Chmiel6, Tim Bushi1, John T. Brooks1, Benjamin Young2
1Colorado School of Mines, Golden, CO, United States, 2Centers for Disease Control and Prevention, Atlanta, GA, United States, 3Cerner Corporation, Vienna, VA, United States, 4University of Alabama School of Medicine, Birmingham, AL, United States, 5Denver Infectious Disease Consultants, Denver, CO, United States, 6Feinberg School of Medicine, Northwestern University, Chicago, IL, United States, 7International Association of Providers of AIDS Care, Washington, DC, United States

782 A Randomized Open Label Study for Comparing Two Doses of Zoledronic Acid in HIV Infected Patients
Eugenia Negredo1, Anna Bonjoch2, Nuria Pérez-Alvarez3,4, Arrelly Ornellas3, Jordi Puig5, Cristina Herrera6, Patricia Ecchevarria6, Bonaventura Cidet6
1Lluita contra la Sida Foundation, Germans Trías i Pujol University Hospital, Badalona, Spain, 2Statistics and Operations Research Department, Universitat Politècnica de Catalunya, Barcelona, Spain, 3Department of Econometrics, University of Barcelona, Barcelona, Spain, 4Iniscaya Foundation, Germans Trías i Pujol University Hospital, Badalona, Spain

783 Mechanism of Bone Disease in HIV and HCV: Impact of Tenofovir Exposure and Severity of Liver Disease
James Cutrell1, Naim M. Maalouf2, Song Zhang3, Henning Drechsler4, Ang Gao5, Pablo Tebas2, Roger Bedimo1
1Infectious Diseases, VA North Texas Health Care System, Dallas, TX, United States, 2Center for Mineral Metabolism, University of Texas Southwestern Medical Center, Dallas, TX, United States, 3Clinical Sciences, University of Texas Southwestern Medical Center, Dallas, TX, United States, 4Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX, United States, 5Infectious Diseases, University of Pennsylvania, Philadelphia, PA, United States

Session P-06 Poster Session
Wednesday March 5, 2014, 2:30 pm—4:00 pm
Exhibit Hall D

Hepatic Fibrosis and Other Hepatic Complications

785 Abacavir and Didanosine Enhance Susceptibility To Acetaminophen-Induced Hepatotoxicity
Ana Blas-García1,2, Víctor M. Víctor1,2, Alberto Martí-Rodrigo1, Lara Millán-Medina1, Nadezda Apostolova1,2, Juan V. Esplugues1,2
1Pharmacology, Faculty of Medicine, University of Valencia, Valencia, Spain, 2ISASIB, Valencia, Spain, 3CIBERehd, Valencia, Spain

786 Liver Fibrosis Is Not Uncommon in HIV-Infected Patients Without Viral or Alcoholic Hepatitis
Anchalee Avihingsanon1,2, Salyavit Aflmilaprapu2, Vorapat Sapsrisavat1, Tanakorn Apornpon1, Tawan Mengthigson1, Stephen Kerr1, 2, Gail V. Matthews1, Sharon R. Lewin1, 2, Kiat Ruxrungtham1, 2, and the HIV-NAT 006 study team.
1HIV-NAT, TRCARC, Bangkok, Thailand, 2Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, 3Department of Biochemistry, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, 4Kirby Institute, University of New South Wales, Sydney, Australia, 5Infectious Diseases, Alfred Hospital and Monash University, Melbourne, Australia, 6Centre for Biomedicine, Burnet Institute, Melbourne, Australia, 7Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand

787 Association Between Dideoxynucleoside Analogues (d-Drugs) and End-Stage Liver Disease (ESLD)
Lene Ryom1, Caroline A. Sabini2, Peter Reiss3, Wafaia El-Sadr1, Antonella D. A. Monforte1, Stephane De Wint4, Ole Kirk1, Andrew N. Phillips1, Jens D. Lundgren1, on behalf of the D:A:D Study Group
1Copenhagen HIV Programme and Epidemiklinikken M5132, Rigshospitalet, Copenhagen University Hospital and University of Copenhagen, Faculty of Health and Medical Sciences, Copenhagen, Denmark, 2Research Department of Infection and Population Health, University College London, London, United Kingdom, 3Division of Infectious Diseases and Department of Global Health, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, 4ICAP-Columbia University/Harlem Hospital, New York City, NY, United States, 5Hospital San Paolo, University of Milan, Milan, Italy, 6Infectious Diseases, CHU Saint-Pierre, Brussels, Belgium, 7Kirby Institute, University of New South Wales, Sydney, Australia

788 Microbial Translocation, Immune Activation, Apoptosis and Liver Fibrosis in the MASH Cohort
Marriana K. Baum1, Kenneth E. Sherman2, Sabrina S. Martinez2, Pedro Greer3, Tiffanie Stewart4, Christina Jacobs5, Sonya Luisi1, Kimberly Dixon1, Adriana Campa1
1Stempel College of Public Health and Social Work, Florida International University, Miami, FL, United States, 2Division of Digestive Diseases, University of Cincinnati, Cincinnati, OH, United States, 3College of Medicine, Florida International University, Miami, FL, United States
Cumulative Exposure To Ritonavir-Boosted Atazanavir Is Associated With Cholelithiasis
Takeshi Nishijima1,2, Hiroyuki Gatanaga1,2, Takuro Shimbro1, Yohei Hamada1, Junko Tanuma1, Kunihisa Tsukada1, Katsushi Teruya3, Yoshimi Kikuchi1, Shinichi Oka1
1AIDS Clinical Center, National Center for Global Health and Medicine, Tokyo, Japan, 2Department of AIDS Research, Kumamoto University, Kumamoto, Japan, 3Department of Clinical Study and Informatics, Center for Clinical Sciences, National Center for Global Health and Medicine, Tokyo, Japan

Prevalence of Liver Fibrosis Based On Non-Invasive Markers Among HIV-Infected Patients in Zambia
Michael J. Vinikoor1,2, Kalo Musukuma3, Gilles Wandel4, Arianna Zanolini2,3, Aggrey Mweemwa2, Carolyn Bolton-Moore1,5, Izzukanji Sizakwe6, Benjamin H. Chi7, Lloyd Mulenga1,4
1Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, 2Institute of Global Health and Infectious Diseases, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 3Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland, 4University Teaching Hospital, Lusaka, Zambia, 5Obstetrics and Gynecology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Significance of Alcohol Abuse Diagnosis vs Other Risk Factors for Advanced Liver Fibrosis by FIB-4
H. Nina Kim1, Heidi M. Crane2, Carla V. Rodriguez3, Steven Van Rompaey4, W. Christopher Mathews5, Michael Mugavero6, Kenneth H. Mayer7, Katerina Christopoulou8, Sonia Naprawski9, Mari M. Kihata10
1University of Washington, Seattle, WA, United States, 2University of California San Diego, La Jolla, CA, United States, 3University of Texas, University of Alabama at Birmingham, Birmingham, AL, United States, 4Fenway Health, Harvard University, Boston, MA, United States, 5University of California San Francisco, San Francisco, CA, United States, 6University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Predictors of Progression, Stabilisation, or Improvement of eGFR After Chronic Renal Impairment
Lene Ryom1, Amanda Mocroft2, Ole Kirk3, Peter Reiss4, Michael Ross5, Olivier Moranne6, Philippe Morlat7, Colette Smith8, Christoph A. Fux9, Jens D. Lundgren10, on behalf of the D:A:D Study Group
1Copenhagen HIV Programme and Epidemiikkiklinikki M5122, Rigshospitalet, Copenhagen University Hospital and University of Copenhagen, Faculty of Health and Medical Sciences, Copenhagen, Denmark, 2Infection and Population Health, University College London, London, United Kingdom, 3Division of Infectious Diseases and Department of Global Health, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, 4Nephrology and Public Health Departments, CHU de Nice, Nice, France, 5Service de Médecine Interne et Maladies Infectieuses, Hôpital Saint-André, CHU de Bordeaux, Bordeaux, France, 6Clinic for Infectious Diseases and Hospital Hygiene, Kantonsspital Aarau, Aarau, Switzerland

Spectrum of HIV-Associated Kidney Disease in the Era of Combination Antiretroviral Therapy
John Booth1, Lisa Hamzah2, Sophie Jose2, Stephen Mcadoo3, Emil Kumar4, Catherine Horsfield5, Patrick O’Donnell6, Rachael Jones7, Caroline Sabin8, Frank A. Post2
1University College London, London, United Kingdom, 2King’s College London, London, United Kingdom, 3Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom, 4Chelsea and Westminster NHS Foundation Trust, London, United Kingdom

Renal and Metabolic Safety of Initial HIV-1 Therapy in Resource-Limited Settings
Francine Touzard Romo1, Laura M. Smeaton2, Thomas B. Campbell3, Cynthia Riviere4, Rosie Mngabiza5, Khuanchai Supparapinto6, Johnstone Kunwenda7, Nagalingeswaran Kumaramasam4, James G. Hakim5, Timothy Flanigan1
1The Miriam Hospital, Providence, RI, United States, 2Harvard School of Public Health, Boston, MA, United States, 3University of Colorado Denver, Aurora, CO, United States, 4Les Centres GHESKIO, Port-au-Prince, Haiti, 5University of KwaZulu Natal, Durban, South Africa, 6Chiang Mai University, Chiang Mai, Thailand, 7College of Medicine, Blantyre, Malawi, 8YRG Care Medical Centre, Chennai, India, 9University of Zimbabwe College of Health Sciences, Harare, Zimbabwe, 10Brown Medical School, Providence, RI, United States

Risk Factors for Atazanavir (ATV)-Associated Urolithiasis: A Case-Control Study
Barbara De Sousa1, Diane Ponscarme1, Nathanael Lapidus2, Michel Daudon3, Laurence Weiss4, Christophe Roux5, Erwan Fourn6, Christine Katlama4, Jean-Michel Molina1, Mathieu Laborie1
1Infectious Diseases Unit, Hôpital Saint Louis, Paris, France, 2Hôpital Tenon, Paris, France, 3Hôpital Européen Georges Pompidou, Paris, France, 4Hôpital Bichat, Paris, France, 5Hôpital Bicêtre, Paris, France, 6Hôpital Pitié, Paris, France

Single Nucleotide Polymorphisms in UGT1A1 Associate With Atazanavir-Related Nephrolithiasis
Takeshi Nishijima1, Kyotou Tsuchiya1, Akane Joyo1, Yohei Hamada2, Junko Tanuma1, Kunihisa Tsukada3, Katsushi Teruya4, Yoshimi Kikuchi3, Shinichi Oka1, Hiroyuki Gatanaga5
AIDS Clinical Center, National Center for Global Health and Medicine, Tokyo, Japan

Atazanavir and Tenofovir Attenuate the Benefit of Antiretroviral Therapy On Cystatin C: ACTG A5224
Chris T. Longenecker1,2, Douglas Fitch3, Paul Sax4,5, Eric Daar4,6, Camlin Tierney1, Grace A. McComsey7,8
1Case Western Reserve University School of Medicine, Cleveland, OH, United States, 2University Hospitals Case Medical Center, Cleveland, OH, United States, 3Harvard School of Public Health, Boston, MA, United States, 4Harvard Medical School, Boston, MA, United States, 5Brigham and Women’s Hospital, Boston, MA, United States, 6Los Angeles Biomedical Research Institute, Torrance, CA, United States, 7David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, United States

A Chronic Kidney Disease Risk Score To Determine Tenofovir Safety Among HIV+ Male Veterans
Rebecca Scherer1, Monica Gandhi2, Michelle Estrella3, Phyllis Tien4, Steven Deeks5, Carl Grunfeld6, Carmen Peralta7, Michael Shlipak8
1University of California San Francisco, San Francisco, CA, United States, 2Johns Hopkins University, Baltimore, MD, United States

Genetic Variants of ABC22 and ABC20 Are Associated With TFV-Induced Proximal Tubular Dysfunction
Anchalee Avihingsanon1,2, Baralee Punnawudth1, Korkariat Praditpornsilpa1, Yingyos Avihingsanon2, Wirach Maek-a-nantawat1, Jiratchaya Sophonphan2, Sasiwimol Ubolyam2, Stephen Kerr1, David Burger1, Kiat Ruxrungtham1, Hiroyuki Gatanaga1, 2, Takuro Shimbo3, Yohei Hamada1, Matthieu Lafaurie1
1Infectious Diseases Unit, Hôpital Saint Louis, Paris, France, 2Hôpital Saint Antoine, Paris, France, 3Hôpital Tenon, Paris, France, 4Hôpital Saint Louis, Paris, France, 5Obstetrics and Gynecology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

End-Stage Kidney Disease and Kidney Transplantation in HIV-Positive Patients
Esther N. Gathogo1, Sophie Jose2, John Booth3, Stephen P. McAdoo4, Emil A. Kumar5, Michael Rayment6, Clifford Leen7, Deborah Williams8, Caroline Sabin9, Frank Post1
1Rensia Sciences, King’s College London, London, United Kingdom, 2University College London, London, United Kingdom, 3Imperial College London, London, United Kingdom, 4Chelsea and Westminster Hospital, London, United Kingdom, 5Western General Hospital, Edinburgh, United Kingdom, 6Brighton and Sussex University Hospitals, Brighton, United Kingdom

Osteoporosis: ART and Animal Models
Maraviroc, a CCR5 Antagonist, Alters Gut Microbiota Composition in a Mouse Model of Obesity
Patricia Perez-Matute1, Laura Perez-Martinez2, José R. Blanco3, Jose A. Oteo1
1Infectious Diseases, CIBIR, Logroño, Spain, 2Infectious Diseases, Hospital San Pedro-CIBIR, Logroño, Spain
812 Symptom-Based Screening for Tuberculosis Among Pregnant Women Living With HIV in Kenya
Surbhi Modi1, Joseph S. Cavanagh2, Ray W. Shiraishi3, Barbara Burmenn2, Heather Alexander3, Kimberly McCarthy4, Hellen Mutuli1, Kevin F. Ca1
1Division of Global HIV/AIDS, Centers for Disease Control and Prevention, Atlanta, GA, United States, 2Division of Tuberculosis Elimination, Centers for Disease Control and Prevention, Atlanta, GA, United States, 3Kenyaa Medical Research Institute/Centers for Disease Control and Prevention Public Health Collaboration, Kisumu, Kenya, 4Division of Global HIV/AIDS, Centers for Disease Control and Prevention, Kisumu, Kenya, 5Division of Tuberculosis Elimination, Centers for Disease Control and Prevention, Kisumu, Kenya

813 Highly Multiplexed Detection of Antibodies in Whole Blood During Tuberculosis Infection
Charles Gref1, Greg Husar1, Christen Gray2, David Danks3, Pamela Nabeta3, Mark Perkins3, Michael Lochhead4
1MBio Diagnostics, Inc, Boulder, CO, United States, 2FIND, Geneva, Switzerland, 3Carnegie Mellon University, Pittsburgh, PA, United States

814 Performance of the World Health Organization Algorithm for Tuberculosis Screening in Kenya
Surbhi Modi1, Joseph S. Cavanagh2, Ray W. Shiraishi3, Barbara Burmenn2, Heather Alexander3, Kimberly McCarthy4, Hellen Mutuli1, Kevin F. Ca1
1Division of Global HIV/AIDS, Centers for Disease Control and Prevention, Atlanta, GA, United States, 2Division of Tuberculosis Elimination, Centers for Disease Control and Prevention, Atlanta, GA, United States, 3Kenyaa Medical Research Institute/Centers for Disease Control and Prevention Public Health Collaboration, Kisumu, Kenya, 4Division of Global HIV/AIDS, Centers for Disease Control and Prevention, Kisumu, Kenya, 5Division of Tuberculosis Elimination, Centers for Disease Control and Prevention, Kisumu, Kenya

815 Diagnosing Extra Pulmonary Tuberculosis Using Xpert MTB/RIF: A Laboratory Algorithm
Lesley E. Scott1, Natalie Beylis2, Mark Nicoll3, Tintswalo Nkuna4, Sabela Molapo4, Leigh Berrie1, Adriano Duse2, Wendy S. Stevens1
1Molecular Medicine and Haematology, University of the Witwatersrand, Johannesburg, South Africa, 2Division of Clinical Microbiology and Infectious Diseases, University of the Witwatersrand, Johannesburg, South Africa, 3Division of Medical Microbiology, Clinical Laboratory Sciences and Institute for Infectious Disease, University of Cape Town, Cape Town, South Africa

Session P-R4 Poster Session
Wednesday March 5, 2014, 2:30 pm–4:00 pm
Exhibit Hall D
Inflammatory and Immune Activation Markers in TB
819 Baseline Inflammatory and Immune Activation Markers Predictive of TB After ART Initiation
Mark Tentorfe1, Nikhil Gupta2, David Dowdy2, David Asmuth1, Ashwin Balagopals3, Richard Pollard3, James Hakim4, Richard Semba5, Thomas Campbell5, Amita Gupta2, for the ACTG A5175s (PEARLS) and NCWS 319 Study Group
1Medicine, Johns Hopkins University, Baltimore, MD, United States, 2Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, 3University of California Davis, Medical Center, Sacramento, CA, United States, 4University of Zimbabwe College of Health Sciences, Harare, Zimbabwe, 5Johns Hopkins University, Baltimore, MD, United States, 6University of Colorado Denver, Aurora, CO, United States

820 MAIT Cells Are Highly Enriched in the Bronchoalveolar Lavage Fluid of Patients With TB
Emily B. Wong1, Zuri Sullivan1, Marielle C. Gold2, Umesh G. Laloo3, Anish Ambaram3, Prinita Bailajh4, Leon Naidoo5, Thumbi Nudungui6, William R. Bishai2, David M. Lewinsohn7,8
1KwaZulu Natal Research Institute for Tuberculosis and HIV, Durban, South Africa, 2Division of Infectious Diseases, Massachusetts General Hospital, Boston, MA, United States, 3Division of Pulmonary and Critical Care Medicine, Oregon Health & Science University, Portland, OR, United States, 4Portland Veterans Administration Medical Center, Portland, OR, United States, 5Department of Pulmonology and Critical Care, Nelson R. Mandela School of Medicine, Durban, South Africa, 6University of Colorado Denver, Aurora, CO, United States, 7HIV Pathogenesis Programme, University of KwaZulu Natal, South Africa, 8Division of Infectious Diseases, Johns Hopkins School of Medicine, Baltimore, MD, United States

821 Vitamin D and TME161J Host Variants Associated With TB or Death in HIV-Infected and -Exposed Infants
Amita Gupta1, Jennifer Jubuis2, Bret Zeldow3, Grace Montepiedra1, Barbara Detrick1, Ayu Vioirl1, Shabir A. Madh1, Charles Mitchell1, Stephen A. Specter2, for the IMPACT NWC113 and P1041 Study Team
1Medicine, Johns Hopkins University, Baltimore, MD, United States, 2Pediatrics, Maine Medical Center/Tufts University, Portland, ME, United States, 3Harvard School of Public Health, Boston, MA, United States, 4Pathology, Johns Hopkins University, Baltimore, MD, United States, 5PHRU, University of the Witwatersrand, Johannesburg, South Africa, 6University of the Witwatersrand, MRC: Respiratory and Meningeal Pathogens Research Unit, Johannesburg, South Africa, 7University of Miami Miller School of Medicine, Miami, FL, United States, 8Medicine, University of California San Diego, La Jolla, CA, United States

822 Latent and Active TB Infection Increase Harmful Immune Activation in Those Co-Infected With HIV
Zuri A. Sullivan1, Emily B. Wong1, Thumbi Nudungu2, Victoria O. Kasprovic3, William R. Bishai1
1KwaZulu Natal Research Institute for Tuberculosis and HIV, Durban, South Africa, 2School of Medicine, Johns Hopkins University, Baltimore, MD, United States, 3HIV Research Program, CDC, United States

823 Ex Vivo Fitness of MTB Correlates With Lysozyme Sensitivity in the East-African Indian Lineage
Claire Pardieu1, Nicola Casal1, Simon Clark2, Ann Rawkins2, Richard Hooper1, Priyam Veji3, Ximena Gonzalo1, Jane R. Deayton4, Francis A. Drobne1
1Clinical TB and HIV Group, Queen Mary University of London, London, United Kingdom, 2TB Research Group, Public Health England, Salisbury, United Kingdom, 3Centre for Primary Care and Public Health, Barts and The London School of Medicine and Dentistry, London, United Kingdom, 4National Mycobacterium Reference Laboratory, Public Health England, London, United Kingdom, 5Centre for Immunology and Infectious Disease, Barts and The London School of Medicine and Dentistry, London, United Kingdom

Session P-R3 Poster Session
Wednesday March 5, 2014, 2:30 pm–4:00 pm
Exhibit Hall D
Latent TB Screening and Treatment
816 Rifampicin Safety and PK With Novel Dosing Strategies To Increase Drug Exposures for TB: ACTG A5311
Kelly E. Dooley1, Radia Savic1, Jeong-Gun Park1, Yoninah Cramer2, Richard Hafnir1, Jennifer Janik1, Mark A. Marzinkle3, Marc Weiner2, Susan Dormann1, David W. Haas1, and the A5311 Study Team
1Johns Hopkins University School of Medicine, Baltimore, MD, United States, 2University of California, San Francisco, CA, United States, 3Statistical and Data Analysis Center, Harvard School of Public Health, Boston, MA, United States, 4Division of AIDS, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, 5Frontier Science Foundation, Amherst, NY, United States, 6Veterans Administration Medical Center, San Antonio, TX, United States, 7Vanderbilt University School of Medicine, Nashville, TN, United States

817 Three Months of Weekly Rifampicin + INH for M. tuberculosis Infection in HIV-Infected Persons
Timothy Sterling1, Connie Benson2, Nigel Scott3, Jose Miro4, Guilherme Calvet1, Richard Chaisson2, Alberto La Rosa2, Rosa Infante2, Michael Chen3, Elsa Villarino1, TBCT / ACTG
1Medicine/Infected Diseases, Vanderbilt University, Nashville, TN, United States, 2University of California at San Diego, San Diego, CA, United States, 3Centers for Disease Control and Prevention, Atlanta, GA, United States, 4Barcelona Department of Health, Barcelona, Spain, 5Instituto de Pesquisa Clinica Evandro Chagas, Rio de Janeiro, Brazil, 6The Johns Hopkins University, Baltimore, MD, United States, 7Impacta, Lima, Peru

818 Effect of HIV On Latent TB Screening of Pregnant Women in Pune, India
Jyoti S. Mathad1, Ramesh Bhosale1, Savita Kanade1, Prasad Deshpande2, Vandana Kulka1mi, Neetal Newrekar3, Vidya Mave2, Nishi Suryavanshi2, Nikhil Gupta1, Amita Gupta1
1Weill Cornell Medical College, New York, NY, United States, 2Byramjee Jeejeebhoy Government Medical College-Sassoon General Hospital, Pune, India, 3Johns Hopkins University-Byramjee Jeejeebhoy Government Medical College Clinical Trials Unit, Pune, India, 4Johns Hopkins University School of Medicine, Baltimore, MD, United States
824 Polyfunctionality of TB-Specific CD4+ T-Cells in HIV-TB Co-Infection in Latent and Pulmonary TB
Puja Van Epps1,2, Sankar Sridaran3, Htin Aung1, Michael R. Betts1, Zahra Toosi1, David H. Canaday3,4
1Department of Medicine, Division of Infectious Diseases and HIV Medicine, Case Western Reserve University, Cleveland, OH, United States, 2Geriatric Research Education & Clinical Center (GRECC), Louis Stokes Cleveland VA Medical Center, Cleveland, OH, United States, 3Department of Microbiology, University of Pennsylvania, Philadelphia, PA, United States

825 Increased Risk of TB and Persistent Immune Deficit With Delayed ART: A Randomized Trial From Haiti
Sean E. Collins1, Marc Antoine Jean Juste2, Patricia Severo3, Serena P. Koeing1, Rôde Secours2, Oksana Ocheretina1, Daphne Bernard1, Allison Dunning1, Sandra M. Hurtado Rúa1, Jean W. Pape2,3
1Center for Global Health, Department of Medicine, Weill Cornell Medical College, New York, NY, United States, 2Groupe Haïtien d’Étude du Sarcome de Kaposi et des Infections Opportunistes, Port au Prince, Haiti, 3Division of Global Health Equity, Brigham and Women’s Hospital, Boston, MA, United States, 4Department of Public Health, Weill Cornell Medical College, New York, NY, United States

826 Viral Suppression in HIV-Infected Pregnant Women With and Without TB, South Africa
Jennifer Hoffmann1, Silvia Cohn2, Filidha Mashabela1, Reginad Msandiwazi1, Richard Chaisson1, Neil Martinson1, Tshepo Study Team1
1The Johns Hopkins University, Baltimore, MD, United States, 2Perinatal HIV Research Unit, Soeto, South Africa

827 Depleted DHEA-S Reserves Are Associated With Early Mortality After ART Initiation in HIV/TB
Shruthi Ravimohan1,2, Neel Tamhula1, Andrew P. Steenhoff3,4, Rona Leathlogile1, Kebatshabile Nfanyana1, Tumelo Rantleru1, Michael Adur1, Drew Weissman1,4, Gregory P. Bisson1,4
1Department of Medicine, Division of Infectious Diseases, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, United States, 2Department of Pediatrics, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, United States, 3Mortality and Morbidity, Division of Global Health Equity, Brigham and Women’s Hospital, Boston, MA, United States, 4Department of Global Health, Weill Cornell Medical College, New York, NY, United States

828 Impacts of National ART Initiation Policy Change On Integrated TB HIV Practice in Zomba, Malawi
Kevinn D. Bezanson1, Adrienne K. Chan1, Monique van Lettow2, Jean Bourgeois1, Edson Mwinjiwa2, Harry Mbewe3, Donald Cole4, Sunmeet Soothi1
1Dignitas International, Toronto, ON, Canada, 2Dignitas International, Zomba, Malawi, 3Zomba Central Hospital, Zomba, Malawi, 4Dalla Lana School of Public Health, Toronto, ON, Canada

830 Does Long-Term ART Reduce TB Rates To Background Population Levels? Data From a National HIV Cohort
Rishi D. Gupta1,2, Marc Lipman1, Alison Brown1, Brian Rice2, Anton Pozniak3,4, Dominik Zenner1, Lucy Thomas1,2, Ibrahim Abubakar1,2, Valerie Delpech2,3
1Institute of Infectious Diseases and Molecular Medicine, University of Cape Town, Cape Town, South Africa, 2Liverpool School of Tropical Medicine, Liverpool, UK, 3Division of Global Health Equity, Brigham and Women’s Hospital, Boston, MA, United States, 4Infectious Diseases, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, United States

831 Development of Tuberculosis in HIV-Infected Patients Receiving Successful TARGA
Esteban Martinez-Echevarria1, Sergio Serrano Villar1, Talia Sainz2, Ana Moreno2, Jose Luis Casado1, Fernando Dronda1, Maria Jesus Perez Elias1, Enrique Nava3, Manuel Rodriguez Zapata1, Santiago Moreno2
1Hospital Universitario Guadalajara, Guadalajara, Spain, 2Hospital Universitario Ramón y Cajal, Madrid, Spain

832 Timeliness of ART Initiation Among HIV-Infected Patients With TB in Sub-Saharan Africa
Suzue Saito1,2, Wafa El-Saddik1,2, Yaël Hirsch-Moverman1, Fai A. Khan, Veronica Mugisha1, Zhuhrina de Silva1, Bahya Elik1,2, Andrea Howard1,2,3
1C4D, Columbia University, New York, NY, United States, 2Department of Epidemiology, Columbia University, New York, NY, United States

833 Antiretroviral Therapy Initiation and Tuberculosis (TB) Risk in the United States (US) and Canada
April Pettit1,2, Adol Mendes1, Sonia Napravnik3, Aimee Freeman1, Bryan Shepherd2, David Dowdy1, Anita Rachlis4, Richard Moore1, Timothy Sterling1,4 for the North American AIDS Cohort Collaboration on Research and Design (NA-ACCORD)
1Vanderbilt University, Nashville, TN, United States, 2Johns Hopkins University, Baltimore, MD, United States, 3University of North Carolina, Chapel Hill, NC, United States, 4Sunnybrook Health Sciences Center, Toronto, ON, Canada

834 Prevalence of Cryptococcal Antigen Positivity Among AIDS Patients, United States From 1986-2012
Jennie L. McKenney1,2, Sean Bauman1, Brandon Neary2, Roger Detels1, Audrey Franklin1, D. Kirk Margolick1, Dominik Zenner1
1Institute of Infectious Diseases and Molecular Medicine, University of Cape Town, Cape Town, South Africa, 2Liverpool School of Tropical Medicine, Liverpool, UK, 3Division of Global Health Equity, Brigham and Women’s Hospital, Boston, MA, United States, 4Infectious Diseases, University of California, Los Angeles, Los Angeles, CA, United States

835 Cryptococcal Disease

836 Monocyte Dysfunction Is Associated With 14-Day Mortality in Cryptococcal Meningitis
James Scriven1, Lisa Graham1, Charlotte Schultz2, Robert Wilkinson1, Britta Urbani1, Graeme Meintjes2, David Lalloo2
1Institute of Infectious Diseases and Molecular Medicine, University of Cape Town, Cape Town, South Africa, 2Liverpool School of Tropical Medicine, Liverpool, United Kingdom

837 Serum Biomarkers Following Induction Therapy for Cryptococcal Meningitis Predict Survival
Joshua Rhein1, James Scriven1, Kathy Huppler Hullsiek1, Maximilian von Hohenberg1, David B. Myers2, Conrad Muzoora3, Graeme Meintjes2, David R. Boulware2
1University of Minnesota, Minneapolis, MN, United States, 2Ifakara Health Institute (IHI), Ifakara, Morogoro, Tanzania, United Republic of, 3Division of Infectious Diseases, University Hospital Bern, Bern, Switzerland, 4Division of Infectious Diseases and Hospital Epidemiology, University Hospital Basel, Basel, Switzerland, 5Division of Infectious Diseases & International Medicine, Department of Medicine, University of Minnesota, Minneapolis, MN, United States

838 Cryptococcal Antigenemia in Severely Immunocompromised HIV Patients in Rural Tanzania
Matthias C. Müller1, Alex J. Ntamuguniro1, Namvua Kimera1, Hansjakob Furrer1, Manuel Battegay2, Marcel Tannier3, Christoph Hatz1, David R. Boulware1, Tracy R. Glass1, Emilio Letang1
1Swiss Tropical and Public Health Institute (Swiss TPH), Basel, Switzerland, 2Ifakara Health Institute (IHI), Ifakara, Morogoro, Tanzania, United Republic of, 3Division of Infectious Diseases, University Hospital Bern, Bern, Switzerland, 4Division of Infectious Diseases and Hospital Epidemiology, University Hospital Basel, Basel, Switzerland, 5Division of Infectious Diseases & International Medicine, Department of Medicine, University of Minnesota, Minneapolis, MN, United States
Session P-R7 Poster Session  
Thursday March 6, 2014, 2:30 PM–4:00 PM  
Exhibit Hall D

OIs Other Than TB and Cryptococcal Disease

849 HSV-2 Serostatus Is Not Associated With Inflammatory or Metabolic Markers in ART-Treated HIV  
Darrell Tan1, Janet Raboud1, Leah Szadkowski2, Tae Joon YI1, Brett Shannon1, Rupert Kauf1, W. Conrad Lies2, Sharon Walmsley3  
1St. Michael's Hospital, Toronto, ON, Canada, 2Toronto General Research Institute, Toronto, ON, Canada, 3University Health Network, Toronto, ON, Canada, 4University of Toronto, Toronto, ON, Canada, 5University of Washington, Seattle, WA, United States

848 Hormonal Contraceptives Increase Innate Immune Effector Molecules in Cervicovaginal Secretions  
Brandon L. Guthrie1, Robert Y. Choi1, Alison C. Roxby2, Rose Bosire1, Barbara Lohman-Payne1, 2, Tahar Hiri2, Carey Farquhar3, 4, Kristina Brodlen3  
1Department of Global Health, University of Washington, Seattle, WA, United States, 2Department of Medicine, University of Washington, Seattle, WA, United States, 3Center for Public Health Research, Kenya Medical Research Institute, Nairobi, Kenya, 4Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden

847 Injectable Contraception and HIV Acquisition in the VOICE Study (MTN-003)  
Lisa M. Noguchi1, 2, Barbra Richardson3, 4, Z. Mike Chirenda5, Gita Ramjee5, Koningsagrie Naier1, Thiesla Palane7, Pearl Sepele6, Ravindre Panchia1, Karla Garzon1, Jeanne Marrazo1, 2, on behalf of the VOICE Study Team  
1Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, 2Microbicide Trials Network, Pittsburgh, PA, United States, 3SCHARP, Seattle, WA, United States, 4UCSF, Harare, Zimbabwe, 5MRC, Durban, South Africa, 6CAPRISA, Durban, South Africa, 7WITS Reproductive Health and HIV Institute, Johannesburg, South Africa, 8Aurum Institute, Klerksdorp, South Africa, 9PHRU, Soweto, South Africa, 10FHI 360, Durham, NC, United States, 11University of Washington, Seattle, WA, United States

Session P-S2 Poster Session  
Thursday March 6, 2014, 2:30 PM–4:00 PM  
Exhibit Hall D

HIV in Women: Pregnancy, Progression, Pap, and Bones

845 Dysregulation of Estradiol Signaling Contributes To Mucosal Barrier Dysfunction HIV+ Women  
Sumathi Sankaran-Walters1, Anne Fenton1, Chris Gaulke2, Lauren Nagy1, Irina Grishina1, Jason Flamm2, Thomas Prindiville1, Satya Dandekar1  
1Medical Microbiology and Immunology, University of CA, Davis, CA, United States, 2Internal Medicine, Kaiser Permanente, Sacramento, CA, United States, 3Internal Medicine, University of CA, Davis, Sacramento, CA, United States

852 HIV Inhibition and Variation in Anti-Microbial Peptides Associated With Intercourse  
J. D. Fortenberry1, Mary A. M. Rogers2, Krystle Fordyc2e, Steven R. King3, David M. Aronoff1, 2, Sari M. Van Anders2  
1Reproductive Health, Moi University School of Medicine, Eldoret, Kenya, 2African Women

846 Early Impact of cART On the Risk of Herpes Zoster: Results From the FHDH-ANRS CO4  
Sophie Grabar1, 2, Pierre Tattevin1, Hana Selinger-Leneman1, Arnaud de la Blanchardiere3, Christian Rabaud4, David Rey1, Vincent Danieluzzi1, Samuel Ferret5, Dominique Costagliola1, Odile Launay1  
1INSERM U943, Paris, France, 2Hôpital Hôtel-Dieu, Unité Biostatistique et Épidémiologie, Université Paris Descartes, Paris, France, 3Hôpital Pontchaillou, Rennes, France, 4CHU Caen, Caen, France, 5INSERM U943, Nancy, France, 6CHU Strasbourg, Strasbourg, France, 7Hôpital Fourestier, Nanterre, France, 8Hôpital St Louis, Paris, France, 9Hôpital Cochin, Paris, France

851 Visual Inspection With Acetic Acid Is Good for Follow-Up After Molecules in Cervicovaginal Secretions  
Barbara Lohman-Payne1, 2, Taha Hirbod4, Carey Farquhar1, 2, Kristina Broliden4  
1Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, GA, United States, 2Internal Medicine, Kaiser Permanente, Sacramento, CA, United States, 3Obstetrics and Gynaecology, University of CA, Davis, Sacramento, CA, United States, 4Center for Public Health Research, Kenya Medical Research Institute, Nairobi, Kenya, 5University of Washington, Seattle, WA, United States

Session P-S1 Poster Session  
Tuesday March 4, 2014, 2:30 pm–4:00 pm  
Exhibit Hall D

Reproductive Hormones in Women: Impact On Risk and Barrier Dysfunction

844 Depot-Medroxyprogesterone Acetate Does Not Increase Genital SHIV Shedding in Macaques  
Jessica Radzio1, Kristzina Hanley1, Debra Hanson1, James Mitchell1, Leeceasia Jenkins1, Sharon Ell1, Frank Deyoung1, Walid Heneine1, J. Gerardo Garcia-Lerma1  
1Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, GA, United States, 2Pathology, Emory University, Atlanta, GA, United States

850 Effect of Antiretroviral Regimens On Bone Mineral Density of HIV Infected Lactating Ugandan Women  
Carolyne Onyango-Makumbi1, Mike Mubiru1, Prossy Ethel Namuli2, Jane Ssebaggala1, Joyce Matovu Namale1, Mary Glenn Fowler1, 2  
1Makerere University - Johns Hopkins University Research Collaboration, Kampala, Uganda, 2Johns Hopkins University, Baltimore, MD, United States

853 Rapid Disease Progression in HIV-1 Subtype C Infected South African Women  
Nigel J. Garrett1, Lisie Werner1, Koleka Mlisana2, Lye McKinnom1, Francois van Loggerenberg3, Thumbi Ndung1u, 4, Olve Gray1, Lynn Morris1, Carolyn Williamson1, Salim Abdool Karim1, 2  
1CAPRISA, Durban, South Africa, 2Department of Medical Microbiology, University of KwaZulu Natal, South Africa, 3The Global Health Network, University of Oxford, United Kingdom, 4HIV Pathogenesis Programme, Durban, South Africa, 5Institute of Infectious Diseases and Molecular Medicine, Cape Town, South Africa, 6Centre for HIV and STIs, Johannesburg, South Africa, 7University of Columbia, New York City, NY, United States

843 Incidence of AIDS-Defining Opportunistic Illnesses (ADOs) Among Patients in North America  
Kate A. Buchacz1, Bryan Lau2, Yuezhou Jing2, Stephen J. Gange2, John T. Brooks1  
1Centers for Disease Control and Prevention, Atlanta, GA, United States, 2Johns Hopkins University, Baltimore, MD, United States

842 Antigen-Presenting Cells Ingest Malaria Parasites and Cause an Increase in HIV-1 Replication  
Marika Orlov1, Florian Vaida1, Kathrin Williamson1, Qianqian Deng1, David Smith1, Patrick Duffy1, Robert Schooley2  
1School of Medicine, University of California San Diego, La Jolla, CA, United States, 2Seattle Biomedical Research Institute, Seattle, WA, United States, 3NIADDK, NIH, Rockville, MD, United States

840 Latent, Acute, or Neuro-Syphilis Does Not Increase HIV-1 Replication in Central Nervous System  
Maximilian Donath1, Timo Wolff1, Annette Haber1, Markus Bickel1, Søri Gøpel1, Annemarie Berger1, Dimitria Bon1, Claudia Brandt1, Christoph Stephan1  
1Goethe University Hospital, Frankfurt, Germany, 2Infectious Diseases, Goethe University Hospital, Frankfurt, Germany, 3Medical Virology Institute, Goethe University Hospital, Frankfurt, Germany, 4Medical Microbiology Institute, Goethe University Hospital, Frankfurt, Germany

Session P-S3 Poster Session  
Thursday March 6, 2014, 2:30 PM-4:00 PM  
Exhibit Hall D

Immune Mediators and Immune Activation in Women
853 Sex-Related Inflammatory Marker Changes Pre- and Post-ART Initiation
Jyoti S. Mathad1, Nikhil Gupta2, Ashwin Balagopal1, David Asmuth1, James Hakim1, Naga lingeswaran Kumarasamy1, Thomas Campbell1, Judith S. Currier2, Susan E. Cohen3, Amita Gupta4, for the NWC5319 and ACTG 5175 PEARLS Study Teams
1Weill Cornell Medical College, New York, NY, United States, 2Johns Hopkins University School of Medicine, Baltimore, MD, United States, 3University of California Davis Medical Center, Sacramento, CA, United States, 4University of Zimbabwe College of Health Sciences, Harare, Zimbabwe, 5YRCARE Medical Centre, Chennai, India, 6University of Colorado at Denver, Denver, CO, United States, 7David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, United States, 8Northwestern University Feinberg School of Medicine, Chicago, IL, United States

854 Influence of RAL vs Boosted ATZ-based Regimens On Cervical Immune Reconstitution and Activation
Amie L. Meditz1, Claire Palmer2, Julie Predhomme3, Kristina Sarafis4, Becky Kerr5, Patricia Caraway5, Edward M. Gardner6, Samantha Malwinney7, Peter L. Anderson8
1Medicine, University of Colorado, Aurora, CO, United States, 2Biostatistics, University of Colorado, Aurora, CO, United States, 3Pharmacy, University of Colorado, Aurora, CO, United States, 4Denver Health Medical Center, Denver, CO, United States

Session P-S4 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM Exhibit Hall D

Immune Response To Vaccination in HIV+ Women

855 AMC 054: Safety and Immunogenicity of the Quadrivalent HPV Vaccine in Indian HIV-Infected Women
Joel Palefsky1, Selvarathu Poongulali2, Shelly Lensing2, Jeanette Lee2, Maria Da Costa3, Arumughan Jeeva4, Syed Iqbal5, Nagalingeswaran Kumarasamy6
1University of California San Francisco, San Francisco, CA, United States, 2YRG Care Medical Centre, Chennai, India, 3University of Arkansas for Medical Sciences, Little Rock, CA, United States

856 B and T Cell Immune Responses To pH1N1 Monovalent Vaccine in HIV+ Pregnant Women in IMPAACT P1086
Adriana Weinberg1, Petronella Muresan2, Kelly Richardson3, Terrence Fenton4, Teresa Dominguez5, Anthony Bloom5, Mark Abzug6, Myron Levin7, Sharon Nachmani8
1Pediatric Infectious Diseases, University of Colorado Denver, Aurora, CO, United States, 2Harvard School of Public Health, Boston, MA, United States, 3Frontier Science & Technology Research Foundation, Amherst, NY, United States

857 Maternal CD4 and Infectious Risk for Uninfected Infants Born To HIV+ Mothers in a European Country
Clement Taron-Brocard1, Jerome Le Chenadec1, Albert Fayel1, Catherine Dollius1, Laurent Mandelbrot2, Vincent Gajdos2, Amia Perilhou3, Jean-Marc Labaune4, Stephanie Blanchon5, Josiane Warszawski6, 7, and the ANRS French Perinatal Cohort (ANRS CO1/CO11)

Posters
874 Detectable Viraemia Among Pregnant Women On Antiretroviral Therapy Initiating Antenatal Care
Landon Myer1, Tamson Phillips1, Allison Zerbe2, Marvin Hislo2, James McIntyre3, Elaine Abrams4
1Division of Epidemiology & Biostatistics, University of Cape Town, Cape Town, South Africa; 2ICAP, Columbia University, New York, NY, United States, 3Department of Virology, University of Cape Town, Cape Town, South Africa, 4Anova Health Institute, Johannesburg, South Africa

875 Steady Decline: Temporal Changes in Substance Use by HIV-Positive Pregnant Women in the US
Kathryn Rough1, Katherine Tassiooulos1, Deborah Kacanek2, Raymond Griner1, Ram Yogev5, Kenneth C. Rich5, George R. Seage4, for the Pediatric HIV/AIDS Cohort Study
1Department of Epidemiology, Harvard School of Public Health, Boston, MA, United States, 2Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, United States, 3Department of Epidemiology, Biostatistics, and Occupational Health, McGill University School of Medicine, Montreal, QC, Canada, 4Ann & Robert H. Lurie Children’s Hospital, Chicago, IL, United States, 5University of Illinois at Chicago, Chicago, IL, United States

Session P-T6 Poster Session

Wednesday March 5, 2014, 2:30 pm–4:00 pm Exhibit Hall D

Early Infant HIV Diagnosis

876 Modeling the Performance and Cost of Early Infant HIV Diagnosis at Birth
Intira J. Collins1, Martina Perazzato1, Dick Chamila1, Anisa Shadrshenas1, Teri Roberts2, Jennifer Coy3, Nicole Ngo-Giang-Huong4, Nathan Shaffer5, Meg Doherty6
1MRC Clinical Trials Unit, London, United Kingdom, 2HIV Department, World Health Organization, Geneva, Switzerland, 3UNICEF, New York, NY, United States, 4Clinton Health Access Initiative, Nairobi, Kenya, 5Division of Reproductive Health, CDC, Atlanta, GA, United States, 6Health Economics and Evaluation, London, United Kingdom

877 Access To Early Infant Diagnosis and Antiretroviral Therapy in Abidjan, Côte d’Ivoire, 2011-2013
Divine Avrit1, Madeleine Failout-Amorissani1, Clarisse Amari-Bossi2, Jeanne Eilaam-Kouakou3, Veronique Mba-Assande4, Edmond Ak4, Irma Abou5, Didier K. EkoMil6, Marguerite Timite-Konan1, Valeriane Leroy8, for the MONOD ANRS 12206 Study Group
1Programme Pacci, Site ANRS, Projet Monod, Abidjan, Côte d’Ivoire, 2Service de Pédiatrie, Centre Hospitalier Universitaire (CHU) Cocody, Abidjan, Côte d’Ivoire, 3Fonds d’Appui-Accompagnement, Programme Pacci, Site ANRS, Projet Monod, Abidjan, Côte d’Ivoire, 4Centre de Prise de Charge, de Recherche et de Formation (CePReF), Site Aconda-vs, Yopougon, Abidjan, Côte d’Ivoire, 5National Program of HIV Care, Abidjan, Côte d’Ivoire, 6Programme Pacci, Site ANRS, Abidjan, Côte d’Ivoire, 7Service de Pédiatrie, Centre Hospitalier Universitaire (CHU) Yopougon, Abidjan, Côte d’Ivoire, 8Insem U207, Bordeaux, France, 9Bordeaux University, Bordeaux, France

Session P-T7 Poster Session

Thursday March 6, 2014, 2:30 pm–4:00 pm Exhibit Hall D

Risk Factors for MTCT

878 Impact of Maternal Incident HIV Infection On Early HIV Vertical Transmission, South Africa in 2011
Thu-Ha Dinh1, Kevin Delaney2, Debra Jackson2, Selam Woldeisenbet3, Yogan Pillay1, Ameena Goga2
1Centers for Disease Control and Prevention, Atlanta, GA, United States, 2School of Public Health, University of the Western Cape, Cape Town, South Africa, 3South Africa Medical Research Council, Cape Town, South Africa, 4National Department of Health, Pretoria, South Africa, 5South Africa Medical Research Council, Pretoria, South Africa

879 Syphilis in HIV-Infected Mothers and Infants: Results From the NICHD/HPTN 040 Study
Nava Yeganeth1, Heather Watts1, Margaret Camarca3, Esaú Joao1, Jose Henrique Pilotto1, Glenda Gray1, Gerhard Theron1, Valdilea G. Veloso2, Lynne M. Mofenson1, Karin Nielsen-Saines3, NICHD HPTN 0401 P0143 Study Team
1Department of Pediatrics, David Geffen School of Medicine, Los Angeles, CA, United States, 2Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD, United States, 3Westat, Rockville, MD, United States, 4Hospital Federal dos Servidores do Estado, Rio de Janeiro, Brazil, 5Hospital Geral de Nova Iguaçu, Nova Iguaçu and Laboratório de AIDS e Imunologia Molecular, Instituto Oswaldo Cruz, Rio de Janeiro, Brazil, 6Perinatal HIV Research Unit, Johannesburg, South Africa, 7Stellenbosch University, Cape Town, South Africa, 8Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil

880 Antiretroviral Adherence Associated With Reduced Breastmilk HIV-1 Transmission: The BAN Study
Nicole L. Davis1, William C. Miller2, Michael G. Hudgens3, Charles S. Chasela4, Dorothy S. Sichali5, Dumbani Kayira6, Athiena P. Kauorts7, Sascha R. Ellington7, Denise J. Jamieson8, Charles M. van der Horst5
1Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 2Epidemiology, Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 3Biostatistics, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 4University of North Carolina Project, Lilongwe, Malawi, 5Division of Reproductive Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, 6Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

881 Cytomegalovirus and Possibly Epstein-Barr Virus in Breast Milk May Facilitate HIV-1 Transmission
Johannes Viljoen1, Edouard Tuaillon2, Nicolas Nagot3, Siva Danaviah4, Marianne Peries5, Prevashinee Padayachee6, Vincent Foulonne7, Ruth Bland8, Nigel Rollins9, Marie-Louise Newell6, Philippe Van De Perre6
1Africa Centre for Health and Population Studies, University of KwaZulu-Natal, Durban, South Africa, 2CHRU de Montpellier, Département de Bactériologie-Virologie, Université Montpellier 1, Montpellier, France, 3Department of Paediatrics & Child Health, University of KwaZulu-Natal, Durban, South Africa

882 Programmatic Implementation of WHO Option B in Botswana Associated With Increased Projected MTCT
Scott Dryden-Peterson1,2,3, Sajini Souda1, Rebecca Zathi4, Jennifer Chen1, Chipo Petlo1, Eidah N. Dintwa5, Retiefetse Lebelonyane5, Mompanti Mmalane5, Sahnin Lockman1,2, Roger L. Shapiro5,6
1Department of Medicine, Brigham & Women’s Hospital, Boston, MA, United States, 2Botsana Harvard AIDS Institute, Gaborone, Botswana, 3University of Botswana, Gaborone, Botswana, 4Department of Medicine, Beth Israel Deaconess Medical Center, Boston, MA, United States, 5Department of Medicine, Massachusetts General Hospital, Boston, MA, United States, 6Ministry of Health, Gaborone, Botswana

883 Impact of Option B+ On Uptake, Retention, and Transmission: A Pre/Post Study in Lilongwe, Malawi
Maria H. Kim1,2,3, Saeed Ahmed1,2, Peter N. Kazembe1, Mina C. Hosseinipour1,2,4, Thomas P. Giordano5, Elizabeth Y. Chiao6, Xiaoying Yu1, Debora Nanthuru2, Mary E. Paul1, Elaine J. Abrams1
1Baylor College of Medicine, Texas Children’s Hospital, Houston, TX, United States, 2Baylor College of Medicine-Abbott Fund Children’s Clinical Center of Excellence, Lilongwe, Malawi, 3UNC Project, Lilongwe, Malawi, 4University of North Carolina School of Medicine, Chapel Hill, NC, United States, 5Department of Medicine, Baylor College of Medicine, Houston, TX, United States, 6Department of Pediatrics, Epidemiology Center, Baylor College of Medicine, Houston, TX, United States, 7ICAP, Mailman School of Public Health, Columbia University, New York, NY, United States

884 Home, Antenatal Clinic or VCT: Preferences of Pregnant Women and Their Partners for Male HIV Testing
Alfred Osoti1,2, Grace John-Stewart3, James Kariie3, John Kinuthia3,4, Barbara Richardson1, Daisy Krakowski1, Carey Farquhar5
1Epidemiology, University of Washington, Seattle, WA, United States, 2Obstetrics and gynecology, University of Nairobi, Nairobi, Kenya, 3Epidemiology, Pediatrics, Medicine, Global Health, University of Washington, Seattle, WA, United States, 4Obstetrics and Gynecology, University of Nairobi, Nairobi, Kenya, 5Research, Kenyatta National Hospital, Nairobi, Kenya, 6Epidemiology, Medicine, Global Health, University of Washington, Seattle, WA, United States
885 Early Infection Among Ugandan HIV-Exposed Infants Whose Mothers Received Option B+ vs Option A  
Julie N. Mugerwa1, 2, Zikishan Namukwaya1, 2, Adeodato Kekitiinwa1, 2, Albert Maganda1, Racheal Auyanga1, Ayoub Kakande1, Joyce Matovu1, Josaphat Byamugisha1, Godfrey Eziri1, Mary G. Fowler1, 2  
1PMTCT, Makerere University, 2Johns Hopkins Research Collaboration (MU-JHU), Kampala, Uganda, 3Baylor College of Medicine Children’s Foundation-Uganda, Kampala, Uganda. 2Pediatrics and Child Health, Makerere University College of Health Sciences, Kampala, Uganda. 3Obstetrics and Gynaecology, Makerere University College of Health Sciences, Kampala, Uganda. 4PMTCT, Ministry of Health, Kampala, Uganda. 5Johns Hopkins University School of Medicine, Baltimore, MD, United States

886 Lay Health Worker Support To Strengthen PMTCT: A Randomised Controlled Trial in South Africa  
Kathryn Stinson1, Debbie van Zyl1, Hlengiwe Msibu1, Jean-Pierre Zeelen2, Christopher J. Colvin1, Leigh F. Johnson1, David Coetzee1, Helen Schneider1  
1Centre for Infectious Disease Epidemiology & Research, University of Cape Town, Observatory, South Africa, 2Community Media Trust, Cape Town, South Africa. 3University of the Western Cape, Cape Town, South Africa

Session P-T9 Poster Session  
Thursday March 6, 2014, 2:30 PM–4:00 PM  
Exhibit Hall D

ART Pharmacokinetics During Pregnancy and Breast-Feeding  
887 Low Darunavir Exposure During Pregnancy With 800/100 mg Darunavir/r QD Dosing  
Angela Colbers1, José Molit1, Jelena Ivanovic2, David Hawkins3, Tariq Sadiq1, Kabanba Kabeja4, Andrea Gintelmaier4, Katharina Weizsäcker4, Graham Taylor1, David Burger2  
1Department of Pharmacy, Radboud University Medical Center, Nijmegen, Netherlands, 2UIeufra la Sìa Foundation, Hospital Universitari Germans Trias i Pujol, Badalona, Spain. 3National Institute for Infectious Diseases “L. Spallanzani”, Rome, Italy. 4Chelse & Westminster Hospital, London, United Kingdom. 5Saint-Pierre University Hospital, Brussels, Belgium. 6Frauenklinik Innensen, Klinikum der Universität München, München, Germany. 7Imperial College Healthcare NHS Trust, London, United Kingdom

888 Pharmacogenetics of Efavirenz Excretion Into Human Breast Milk and Transfer To Breastfed Infants  
Adeniyi Olagunju1, 2, Marco Siccardi3, Ogechi Okofo4, Oluseye Bolaji1, Saye Koo1, Andrew Owen1  
1University of Liverpool, Liverpool, United Kingdom. 2Obafemi Awolowo University, Ile-Ife, Nigeria. 3Bishop Murray Medical Centre, Makurdi, Nigeria

889 Safety, Efficacy, and PK of Atazanavir/Ritonavir (300/100 mg QD) in HIV+ Pregnant Women Cohort  
Minh P. Lê1, Charlotte Charpentier1, Cathia Soulé1, Houria Ichiou2, Julien Potter2, Roland Tubiana3, Sophie Matheron3, Roland Landman4, Laurent Mandrollet1, Gilles Peytavin1  
1Laboratoire de Pharmacologie, AP-HP, Groupe Hospitalier Bichat-Claude Bernard, HUPHWS, Paris, France. 2Laboratoire de Virologie, AP-HP, Groupe Hospitalier Bichat-Claude Bernard, HUPHWS, Paris, France. 3Laboratoire de Virologie, AP-HP, Groupe Hospitalier Pitié-Salpêtrière, Paris, France. 4Laboratoire de Microbiologie, AP-HP, Hôpital Louis Mourier, HUPHWS, Colombes, France. 5Service de Maladies Infectieuses et Tropicales, AP-HP, Groupe Hospitalier Bichat-Claude Bernard, HUPHWS, Paris, France. 6Service de Maladies Infectieuses et Tropicales, AP-HP, Groupe Hospitalier Bichat-Claude Bernard, HUPHWS, Paris, France. 7Service de Gynécologie Obstétrique, AP-HP, Hôpital Louis Mourier, HUPHWS, Colombes, France

900 A Comparison of the Pharmacokinetics of Raltegravir During Pregnancy and Postpartum  
Maren Blonk1, 2, Angela Colbers1, Carmen Hidalgo-Tenorio1, Katharina Weizsäcker1, José Molito3, David Hawkins4, Marchina van den Ende4, Andrea Gintelmaier1, Graham Taylor1, David Burger1  
1PANNA Network 2Department of Pharmacy, Radboud University Medical Center, Nijmegen, Netherlands. 3Hospital Universitario Virgen de las Nieves Granada, Granada, Spain. 4Klinik für Geburtsmedizin, Charité Universitätsmedizin, Berlin, Germany. 5UIeufra la Sìa Foundation, Hospital Universitari Germans Trias i Pujol, Badalona, Spain. 6Chelse & Westminster Hospital, London, United Kingdom. 7Erasmus Medical Center, Rotterdam, Netherlands. 8Femeklinik Innensen, Klinikum der Universität München, München, Germany. 9Imperial College Healthcare NHS Trust, London, United Kingdom

901 Intensive Etravirine PK and HIV-1 Viral Load in Breast Milk and Plasma in HIV+ Women Receiving HAART  
LaShonda Y. Spencer1, Siyu Liu2, Chia-Hao Wang3, Michael Neely4, Stan Louder1, Andrea Kovacs2  
1Pediatric Infectious Diseases, Keck School of Medicine at University of Southern California. Los Angeles, CA, United States. 2University of Southern California School of Pharmacy, Los Angeles, CA, United States

902 Effective Exposure To Atazanavir During Pregnancy, Regardless of Tenofuvir Use  
Angela Colbers1, David Hawkins3, Carmen Hidalgo-Tenorio1, Marchina van den Ende4, Kabanba Kabeja4, Andrea Gintelmaier4, Katharina Weizsäcker4, John Lambert1, Jürgen Rockstroh2, David Burger3  
1Department of Pharmacy, Radboud University Medical Center, Nijmegen, Netherlands. 2Chelsea & Westminster Hospital, London, United Kingdom. 3Hospital Universitario Virgen de las Nieves Granada, Granada, Spain. 4Erasmus Medical Center, Rotterdam, Netherlands. 5Saint-Pierre University Hospital, Brussels, Belgium. 6Frauenklinik Innensen, Klinikum der Universität München, München, Germany. 7Immunologie und Klinikum der Universität Hamburg, Hamburg, Germany. 8Klinik für Gebärmutterheilkunde, Charité Universitätsmedizin, Berlin, Germany. 9Mater and Rotunda Hospitals, Dublin, Ireland. 10Department of Medicine I, University of Bonn, Bonn, Germany. 11Department of Pharmacy, Radboud University Medical Center, Nijmegen, Netherlands

Session P-U1 Poster Session  
Tuesday March 4, 2014, 2:30 PM–4:00 PM  
Exhibit Hall D

ART in Children and Adolescents  
903 P1073: Immune Reconstitution Inflammatory Syndrome - Wide Spectrum and Severity in Children  
Mark F. Cotton1, Hilda Majuru1, Raziya Bobat2, Boniface Njau2, Ayvi Viokari1, Vidiya Mave3, Charles Mitchell4, James Oleske5, Bonnie Zimmer5, Savita Pathwa3  
1Pediatrics & Child Health, Stellenbosch University, Tygerberg, South Africa. 2Pediatrics & Child Health, UZ College of Health Sciences, Harare, Zimbabwe. 3Pediatrics & Child Health, University of Natal, Durban, South Africa. 4Kilimanjaro Christian Medical Centre, Moshi, Tanzania, United Republic of. 5Pediatrics & Child Health, Pointon HIV Research Unit, Tygerberg, South Africa. 6BJ Medical College, Pune, India. 7Pediatric Immunology, University of Miami, Miami, FL, United States. 8Pediatrics & Child Health, New Jersey Medical School, Newark, NJ, United States. 9Frontier Science & Technology Research Foundation, Amherst, NY, United States. 10Pediatrics & Child Health, University of Miami Miller School of Medicine, Miami, FL, United States

904 sDNVP Exposure and ART Response in Children <3 Years Initiating ART in the ARROW Trial  
Philippa Musoke1, Victor Musilme1, Kusum Natho1, Patricia Nahrain-Ntoge1, Alexander J. Szubert1, Kuda Mutas1, David E. Williams2, Moira Spyer2, Ann Sarah Walker1, Diana M. Gibb3  
1Department of Pediatrics, Division of Infectious Diseases, University of Cape Town, Observatory, South Africa. 2Baylor Uganda, Kampala, Uganda. 3Joint Clinical Research Center, Kampala, Uganda. 4University of Zimbabwe, Harare, Zimbabwe. 5MRC/UW Uganda Research Unit on AIDS, Entebbe, Uganda. 6MRC Clinical Trials Unit, London, United Kingdom. 7Zvitambo Institute for Maternal Child Health Research, Harare, Zimbabwe

905 Virologic Response To Efavirenz vs Nevirapine-Containing ART in the ARROW Trial  
Adeodato Kekitiinwa1, Moira Spyer1, Richard Kataramu1, Victor Musilme1, Towanda Mhate1, Sabrina Kitaka1, Oscar Serfunna2, Marshall Munjoma3, Ann Sarah Walker1, Diana M. Gibb3  
1Baylor-Uganda, Kampala, Uganda. 2Joint Clinical Research Center, Kampala, Uganda. 3University of Zimbabwe, Harare, Zimbabwe. 4MRC/UW Uganda Research Unit on AIDS, Entebbe, Uganda. 5Joint Clinical Research Center, Kampala, Uganda. 6University of Zimbabwe, Harare, Zimbabwe

906 Growth Recovery Among HIV+ Children Randomized To Lopinavir/Ritonavir or NNRTI-Based Therapy  
Theodore Ruel1, Abot Kakuru1, Gloria Iklozi1, Florence Mwangwa2, Albert Plenty1, Edwin Charliebois1, Diane Havril1, Moses Kamya2, Jane Achari1  
1Department of Pediatrics, Division of Infectious Diseases, University of California San Francisco, San Francisco, CA, United States. 2Infected
902 Bioequivalence of Two Pediatric Formulations vs Adult Tablet Formulation of Elvitegravir
Joseph M. Custodio1, Xiang Yin2, Hiba Graham3, Mischa Hempner4, Lauren Wiser5, Erin Quirk1, Brian P. Kearney6, Srinivasan Ramannah1
1Clinical Pharmacology, Gilead Sciences, Foster City, CA, United States, 2Biometrics, Gilead Sciences, Foster City, CA, United States, 3Clinical Operations, Gilead Sciences, Foster City, CA, United States, 4Formulations Process Development, Gilead Sciences, Foster City, CA, United States

903 CYP2B6 Polymorphisms Challenge Generalized FDA Efavirenz Dosing Guidelines in Children < 3 Yrs
Carolyn Boilte Moore1, Edmund Capparelli2, Pearl Samson3, Mutsa Bwakura-Dangarembizi4, Patrick Jean-Philippe5, Carol Worrell6, Barbara Heckman1, Lynette Purdie1, Stephen A. Spector7, Ellen G. Chadwick1
1IMPAACT P1070 team 2University of North Carolina Chapel Hill, Centre for Infectious Disease Research in Zamb, Luaka, Zambia, 3University of California San Diego, San Diego, CA, United States, 4Harvard School of Public Health, Boston, MA, United States, 5University of Zimbabwe, Harare, Zimbabwe, 6Kennedy Jackson Foundation/ NIAID/ DAIDS, Bethesda, MD, United States, 7Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD, United States

904 High Nevirapine and Low Lopinavir/Efavirenz Exposures in Resource-Poor Ugandan Children
Imke H. Bartelink1, Rada M. Savic2, Grant Dorsey3, Henriette J. Scherpiber4, Edmund Capparelli5, Jane Achani6, Albert Pint6, Moses Kamya7, Diana Hazlin8, Francesca T. Arewe1, 2Bioengineering and Therapeutic Sciences, University of California San Francisco, San Francisco, CA, United States, 3Medicine, University of California San Francisco, San Francisco, CA, United States, 4Paediatrics, Emma Childrens Hospital AMC, Amsterdam, Netherlands, 5Center for Immunity, Infection & Inflammation, University of California San Diego, La Jolla, CA, United States, 6Medicine, The Makerere University, Kampala, Uganda, 7Center for AIDS Prevention Studies, University of California San Francisco, San Francisco, CA, United States, 8Clinical Pharmacy, University of California San Francisco, San Francisco, CA, United States

905 Bone and Renal Safety at 96 Weeks of TDF-Containing Regimens in HIV-Infected Thai Children
Wasana Prasitsuetsal1, Thanayee Puthanakit2, 3, Tanakorn Apornpong1, Siriwann Keadpubasa1, Torsak Bunupradat, Thongsai Chuanjantra, Narujaporn Thammarajuk1, Thidarat Jupima1, Stephen J. Kerr2, 4Jintan Anawanorac1
1HIV-NAT, TRC4C, Bangkok, Thailand, 2Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, 3The Kirby Institute, University of New South Wales, Sidney, Australia, 4HIV-NAT, SEARCH, TRC4C, Bangkok, Thailand

906LB Safety and Efficacy of Dolasetravigr in HIV Treatment-Experienced Adolescents: 48-Week Results
Rolando M. Vian1, Carmelita Alvero2, Perry Fenton3, Edward Acosta4, Rohan Hazra1, Ellen O’Gara1, Barbara Heckman1, Debra McCarty-Steiners2, Shereen Min4, Andrew Wiznia5, 6University of California San Diego, La Jolla, CA, United States, 7Harvard School of Public Health, Boston, MA, United States, 8University of Alabama, Birmingham, Birmingham, AL, United States, 9Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD, United States, 10National Institutes of Health, NIAID, DAIDS, Bethesda, MD, United States, 11Frontier Science and Technology Research Foundation, Amherst, NY, United States, 12GlaxoSmithKline, Research Triangle Park, NC, United States, 13GSK, Research Triangle Park, NC, United States, 14Jacobi Medical Center, Bronx, NY, United States

907 Simulation and Exposure-Based Assessment of Pediatric Lopinavir Fixed-Dose Combination Product
Saik Urien1, Naim Bouazza2, Frantz Foisiac3, Floris Fauchet3, David Burger, Jean-René Kiechel4, Edmund Capparelli5, Jean-Marc Trekuyer3, Marc Lallemand6, 1Cochin Hospital, Paris, France, 2Radboud University, Nijmegen, Netherlands, 3Drugs for Neglected Diseases Initiative, Geneva, Switzerland, 4University of California San Diego, La Jolla, CA, United States

Session P-U2 Poster Session
Tuesday March 4, 2014, 2:30 pm–4:00 pm  Exhibit Hall D
HIV Drug Resistance and Tropism in Children and Youth

897 Prevalence and Predictors of HIV Drug Resistance Among US Children and Youth With Perinatal HIV
Russell B. Van Dyke1, Kunjal Patel2, Ron M. Kagan3, Shirley Trafare, William A. Meyer1, Katherine Tassiosoulos1, George R. Seage3, Lorna M. Seyboll1, Sandra Burchette1, Rohan Hazra2, and the Pediatric HIV/AIDS Cohort Study 1Department of Pediatrics, Tulane University School of Medicine, New Orleans, LA, United States, 2Department of Epidemiology, Harvard School of Public Health, Boston, MA, United States, 3Quest Diagnostics Nichols Institute, San Juan Capistrano, CA, United States, 4Center for Bioinformatics in AIDS Research, Harvard School of Public Health, Boston, MA, United States, 5Quest Diagnostics, Baltimore, MD, United States, 6Department of Pediatrics, Louisiana State University Health Sciences Center, New Orleans, LA, United States, 7Department of Pediatrics, Harvard Medical School, Boston, MA, United States, 8Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD, United States

898 HIV-1 Resistance After Randomized Virologic Switch at 1000 or 30,000 c/ml in Children
Linda Harrison1, Diana Gibb2, Susan Fievez3, Yacine Said4, Elieni Nastoul5, Lynda Harper6, Alexandra Cimpanacu1, Abdel Babiker7, Ann Melvin1, 8Tudor-Williams2, and the PENPACT 1 (PENTA 9/PACTG 390) Study Team 1Center for Bioinformatics in AIDS Research, Harvard School of Public Health, Boston, MA, United States, 2Medical Research Council, Clinical Trials Unit, London, United Kingdom, 3UNC-Chapel Hill Virology Laboratory, University of North Carolina School of Medicine, Chapel Hill, NC, United States, 4INSERM, SC10, Paris, France, 5University College Hospital, University College London, London, United Kingdom, 6Seattle Children’s Hospital, Seattle, WA, United States, 7Imperial College London, London, United Kingdom

899 Longitudinal Evolution of Tropism in Perinatal HIV-1 Infection: The HICCUP Study
Caroline Foster1, Steve Kay2, Colette Smith2, Nicola Macko2 1900 Clinic, Imperial College Healthcare NHS Trust, London, United Kingdom, 2Jeffries Trust Laboratory, Imperial College London, London, United Kingdom, 3Research Department of Infection and Population Health, University College London, London, United Kingdom, 4Jeffries Wing, Imperial College Healthcare NHS Trust, London, United Kingdom

Session P-U3 Poster Session
Tuesday March 4, 2014, 2:30 pm–4:00 pm  Exhibit Hall D
ARV Pharmacokinetics, Pharmacogenetics, and Safety in Children and Adolescents

900 Rilpivirine Pharmacokinetics in HIV-1-Infected Adolescents: A Substudy of PAINT (Phase II Trial)
Herta Crauwes1, Annetemie Hoogstoot, Simon Vanwegen1, Wayne Yarnall2, Marta Stevens1, Katia Boeni3, 1Janssen Infectious Diseases BVBA, Beersel, Belgium, 2Janssen Research & Development, LLC, Titusville, NJ, United States

901 Safety, Pharmacokinetics and Efficacy of Dolasetravigr in Treatment-Experienced HIV+ Children
Rolando M. Vian1, Carmelita Alvero2, Perry Fenton3, Edward Acosta4, Rohan Hazra1, Ellen O’Gara1, Barbara Heckman1, Debra McCarty-Steiners2, Shereen Min4, Andrew Wiznia5, 1University of California San Diego, La Jolla, CA, United States, 2Harvard School of Public Health, Boston, MA, United States, 3University of California San Francisco, San Francisco, CA, United States, 4Clinical Operations, Gilead Sciences, Foster City, CA, United States, 5University of Alabama, Birmingham, Birmingham, AL, United States, 6Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD, United States, 7National Institutes of Health, NIAID, DAIDS, Bethesda, MD, United States, 8Frontier Science and Technology Research Foundation, Amherst, NY, United States, 9GlaxoSmithKline, Research Triangle Park, NC, United States, 10GSK, Research Triangle Park, NC, United States, 11Jacobi Medical Center, Bronx, NY, United States
908 Bioequivalence of Two Pediatric Formulations vs Adult Tablet Formulation of Cobicistat
Joseph M. Custodio1, Xiang Yin1, Hiba Graham2, Miacha Hepner2, Joanna Kozlara2, Erin Quirk2, Brian P. Keaney3, Shrinivas Ramarathnam1
1Clinical Pharmacology, Gilead Sciences, Foster City, CA, United States, 2Biometrics, Gilead Sciences, Foster City, CA, United States, 3Clinical Research, Gilead Sciences, Foster City, CA, United States, 4Clinical Operations, Gilead Sciences, Foster City, CA, United States, 5Formulations Process Development, Gilead Sciences, Foster City, CA, United States

909 Pharmacokinetics, Efficacy, and Safety of an Integrase Inhibitor STR in HIV-Infected Adolescents
Aditya Gaur1, Jan Fourie2, Kulkanya Chokephaibulkit1, Linda-Gail Bekker1, Xiang Yin1, Joseph M. Custodio1, Sean R. Bennett4, Andrew Chen5, Erin Quirk2
1St Jude’s Children’s Research Hospital, Memphis, TN, United States, 2Mpiati Medical Centre, Dundee, South Africa, 3Queen Siriraj Hospital, Bangkok, Thailand, 4Desmond Tutu HIV Centre, Cape Town, South Africa, 5Gilead Sciences, Inc, Foster City, CA, United States

Session P-U4 Poster Session

Wednesday March 5, 2014, 2:30 pm—4:00 pm Exhibit Hall D
Host and Immune Response in Children and Adolescents

910 Complex Pattern of Inflammatory Biomarkers After ART Initiation in HIV-Infected African Children
Nigel Klein1, Chipo Bereyna2, Godfrey Pimundu3, Pietro Pala4, Tichona Vhembo5, Victor Musilime6, Philip Kaikai7, Hannah Poulsom1, Nigel Klein1, Erin Quirk2
1Queen Mary University of London, London, United Kingdom, 2Harvard School of Public Health, Boston, MA, United States, 3University of Colorado/Children’s Hospital Institute, Los Angeles, CA, United States, 4Harvard School of Public Health, Boston, MA, United States, 5Joint Clinical Research Center, Kampala, Uganda, 6MRC/Uganda Research Unit on AIDS, Entebbe, Uganda, 7Joint Clinical Research Center, Kampala, Uganda

911 Preferential Preservation of Helios+Foxp3+ Regulatory T Cell Subset in HIV Infected Children
Guennet Degaffe, Ramla Zakhour, Weihe Zhang, German Contreras, Cynthia Bell, Gilhen Rodriguez, Gabriela Del Bianco, James Murphy, Gloria P. Heresi, Da Q. Tran
Pediatrics, UT Health, Houston, TX, United States

912 Perturbation of Regulatory T Cell Subsets in HIV Infected Children
Alka Khaitan1, Musa Mwamzuka2, Fatma Marshed2, Adam Kravietz3, Tiina Ilmet4, Swale Said5, Aabid Ahmed6, William Borkowsky1, Derya Unutmaz4
1Virology, Institut Pasteur, Paris, France, 2CESP INSERM U1018, Le Kremlin-Bicêtre, France, 3AP-HP, Paris, France, 4EAS20, Université Paris Descartes, Paris, France

913 Incomplete Immune Reconstitution in HIV-1-Infected Children With Virological Suppression
Paul Krogstad1, Kunjali Patel1, Brad Karulis1, Mark Azbug1, James Olesek2, George Seage3, Andrew Wiznia4, Rohan Hazra5, Russell Van Dyke6, for The Pediatric HIV/AIDS Cohort Study and NIDHSurveillance Investigators
1Pediatrics and Pharmacology, David Geffen School of Medicine, UCLA AIDS Institute, Los Angeles, CA, United States, 2Harvard School of Public Health, Boston, MA, United States, 3University of Colorado/Children’s Hospital Colorado, Aurora, CO, United States, 4Rutgers University, Newark, NJ, United States, 5Albert Einstein School of Medicine, Bronx, NY, United States, 6Northwestern University, Chicago, IL, United States

914 Lower Inflammatory Biomarkers in Children Randomized To Prolonged Cotrimoxazole Prophylaxis
Andrew J. Prendergast1, Mutswashe Bwakura-Dangarembizi1, Victor Musilime2, Joseph Lutaakome3, Adeodata Kekitiinwa3, Godfrey Pimundu3, Annie Shorofa4, Moira Speyr5, Nigel Klein1, Ann Sarah Walker6
1University of Zimbabwe, Harare, Zimbabwe, 2Joint Clinical Research Center, Kampala, Uganda, 3MRC/Uganda Research Unit on AIDS, Entebbe, Uganda, 4MRC Clinical Trials Unit, London, United Kingdom, 5Baylor-Uganda, Kampala, Uganda, 6Gilead Sciences, Inc, Foster City, CA, United States

915 CD127 Expression On Naive T-Cells and HIV Replication in Youths Infected in the Perinatal Period
David Scott-Algara1, Jérôme Le Chenadec2, Josiane Warszawski2, Thomas Montange1, Jean-Paul Viard3, Catherine Doullot4, Véronique Avettand-Vernois5, Christine Rouzioux1, Stéphane Blanchet1, Florence Buseyne1
1Virology, Institut Pasteur, Paris, France, 2CESP INSERM U1018, Le Kremlin-Bicêtre, France, 3AP-HP, Paris, France, 4EAS20, Université Paris Descartes, Paris, France

Session P-U5 Poster Session

Wednesday March 5, 2014, 2:30 pm—4:00 pm
Exhibit Hall D
Complications of HIV in ART and Children and Adolescents

916 Pediatric HIV Infection and Dental Caries in the Era of Antiretroviral Therapy in West Africa
Noella Rajonson1, David G. Melewis2, Boubacar Ba2, Malick Fay2, Jean-Serge Dity3, Serge N’zoré4, Sébastien Dutte5, François Dabis6, Shiboski Caroline7, Elise Arrévié8
1HKP, Université Bordeaux-Ségalen, Bordeaux, France, 2APCCI, Abidjan, Côte d’Ivoire, 3ICU d’Odroto-Stomatologie, Bamako, Mali, 4Hôpital d’Enfants Albert Royer, Dakar, Senegal, 5PMY Popuyogon-Atrid, Abidjan, Côte d’Ivoire, 6CCTOS, Abidjan, Côte d’Ivoire, 7Department of Ophthalmal Sciences, University of California San Francisco, San Francisco, CA, United States

917 Preclinical Atherosclerosis in Eastern Africa: Results From a Pediatric Ethiopian Cohort
Julia C. Rosebusch1, Rudolph L. Gleason2, Alexander Cauk1, Daniel Selifu1, Allison Eckard1, Workheabeba Taye3
1Infectious Diseases, Emory University, Atlanta, GA, United States, 2Biomedical Engineering, Georgia Institute of Technology, Atlanta, GA, United States, 3Gilead Sciences, Foster City, CA, United States, 4Formulations Process Development, Gilead Black Lion Hospital, Addis Ababa, Ethiopia, 5Pediatrics, Black Lion Hospital, Addis Ababa, Ethiopia

918 Insulin Resistance in HIV-Infected Youth Is Associated With Decreased Mitochondrial Respiration
Jody K. Takenoto1, Jiaying Wang1, Denise L. Jacobson2, Tracie L. Miller3, Mitchell E. Geffner4, Russell B. Van Dyke5, Daniel E. Libuti6, Patricia Graham6, Mariana Gershenson7, for the Pediatric HIV/AIDS Cohort Study
1Cell and Molecular Biology, University of Hawaii, Honolulu, HI, United States, 2Harvard School of Public Health, Boston, MA, United States, 3University of Miami, Miami, FL, United States, 4Children’s Hospital Los Angeles, Los Angeles, CA, United States, 5Tulane University Health Sciences Center, New Orleans, LA, United States

919 The Effect of Long-Term Zidovudine On Hematological Parameters in the ARROW Randomized Trial
Victor Musilime1, Adrian Cook1, Patricia Nahirya-Ntege2, Mutswashe Bwakura-Dangarembizi1, Adeodata Kekitiinwa1, Margaret Thomason1, Richard Katuramu1, Philippa Musoke1, Ann Sarah Walker6, Diana M. Gibb2, and the ARROW Trial Team
1Virology, Institut Pasteur, Paris, France, 2CESP INSERM U1018, Le Kremlin-Bicêtre, France, 3AP-HP, Paris, France, 4EAS20, Université Paris Descartes, Paris, France

920 Bone Quality Determination by Ultrasonometry in Young South African HIV-Infected Children
Stephen M. Arpadi1, Stephanie Shiau1, Jonathan J. Kaufman2, Ashraf Coovadia3, Renate Strehius4, Francoise Pinillos5, Michael T. Yin2
1Columbia University, New York, NY, United States, 2Mount Sinai School of Medicine, New York, NY, United States, 3University of the Witwatersrand, Johannesburg, South Africa

Session P-U6 Poster Session

Thursday March 6, 2014, 2:30 pm—4:00 pm Exhibit Hall D
Response To Early ART Initiation in Infants

922 Routine Antibody Tests Have No Place in Determining HIV Status After Early ART: Evidence From CHER
Helen Payne1,2, Nonhlanhla Mkhize3, Lynn Morris4, Kennedy Owombe5, Ravindre Panchia1, Avy Violari6, Nigel Klein1, Abdel G. Babiker5, Mark F. Cotton7, Diana M. Gibb8
1Columbia University, New York, NY, United States, 2Mount Sinai School of Medicine, New York, NY, United States, 3Virology, Institute Pasteur, Paris, France, 4CESP INSERM U1018, Le Kremlin-Bicêtre, France, 5AP-HP, Paris, France, 6EAS20, Université Paris Descartes, Paris, France
923 Different Profiles of HIV in Early Treated HIV-Infected Children Seronegative by ELISA in Cameroon

Mathurin C. Tejokem1, Antunbom Ktuwha2, Francis Atiba Ndongo1, Suzie Tetang Nding1, Lisa Calixte Pendé1, William Mbarsoum2, Lilian Owona1, Josiane Warszawski3, Christine Rouzioux1, Albert Fayel1, 2

1Service d’Epidémiologie et de Santé Publique, Centre Pasteur du Cameroun, 2Service de Virologie, Centre Pasteur du Cameroun, 3Membre du Réseau International des Instituts Pasteur, Yaoundé, Cameroon, 4Centre de Dépistage, Centre Hospitalier d’Essos, Yaoundé, Cameroon, 5Hôpital de Jour, Hôpital Lapurquisite de Douala, Douala, Cameroon, 6Université de Douala, Faculté de Médecine et des Sciences Pharmaceutiques, Douala, Cameroon, 7EPF, Equipe 4 (VH et IST), INSERM U1019 (CESP), Le Kremlin Bicêtre, France, 8Université de Paris Sud 11, Paris, France, 9Laboratoire de Virologie, Assistance_publique des Hôpitaux de Paris, Hôpital Necker, Paris, France, 10Université Paris Descartes, EA 3620, Paris, France, 11Pédiatrie Générale, Assistance_publique des Hôpitaux de Paris, 12Hôpital Robert Debré, Paris, France, 13Université Paris 7 Denis Diderot, Paris Sorbonne Cité, Paris, France

924 Greater Virologic Control in Infants Initiated On ART Before 6 Months of Age

Stephanie Shiau1, Astrophil Coovadia1, Karl Gunter Technau1, Renate Strekalovskaia1, Leigh Martin2, Francois Perillo2, Elaine J. Abrams2, Louise Kuhn3, 1Columbia University, New York, NY, United States, 2University of the Witwatersrand, Johannesburg, South Africa

925 Early Viral Suppression Improves Neurocognitive Outcomes in HIV-Infected Children

Claudia S. Crowell1, Yanling Hu2, Katherine Tassiopoulos1, Kathleen M. Male1, Ram Yog2, Rohan Hazra1, Richard M. Rutstein1, Sharon L. Nichols2, Renee A. Smith2, William J. Muller3, for the IMPACT 219C Study Team and the Pediatric HIV/AIDS Cohort Study

1Pediatrics, University of Washington, Seattle, WA, United States, 2Epidemiology, Harvard School of Public Health, Boston, MA, United States, 3Epidemiology, Northwestern University Feinberg School of Medicine, Chicago, IL, United States, 4National Institute of Child Health and Human Development, Bethesda, MD, United States, 5Children’s Hospital of Philadelphia, Philadelphia, PA, United States, 6University of California San Diego, La Jolla, CA, United States, 7University of Illinois at Chicago, Chicago, IL, United States

926 Early Cytomegalovirus Viraemia and Clinical Outcomes of HIV-Infected Children in the Early ART Era

Nei-yuan Hsiao1,2,1, Kennedy Otowobi1,2,1, Landon Myer1,2,1, Ary Violar1,2,1, Diana Gibb1,2,1, Ravindre Panchi1,2,1, Abdul Bakker1,2,1, Patrick Jean-Phillipe1,2, Mark Fredric Cotten1,2

1Clinical Laboratory Sciences, University of Cape Town, Cape Town, South Africa, 2Perinatal HIV Research Unit, Johannesburg, South Africa, 3Public Health and Family Medicine, University of Cape Town, Cape Town, South Africa, 4Medical Research Council UK, London, United Kingdom, 5National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, 6Paediatrics and Child Health, Stellenbosch University, Cape Town, South Africa

927 Risk Factors Associated With TB in Children Receiving ART in a South African Multicenter HIV Cohort

Alana T. Brennan1,2, Mhairi Maskew1,2, Kate Schnippel1,2, Ian Sanne1,2, Lawrence Long1,2, Matt P. Fox1,2

1Center for Global Health & Development, Boston University, Boston, MA, United States, 2Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa

928 Hepatitis B Treatment Response To TDF in 3TC-Experienced Perinatally HIV-Infected Adolescents

Linda Aurubil1, Pakagron Lumbiganon1, Pope Kosalaktrasak1, Rawin Hansudvedthachai2, Pawanee Taerpaisarset1, Torsak Bunupuroat1, Tryanyee Puthanakit1, 2, Khuanchai Supparatpinyo1

1Chiang Mai University, Chiang Mai, Thailand, 2Khon Kaen University, Khon Kaen, Thailand, 3Chiang Rai Prachanukroh Regional Hospital, Chiang Rai, Thailand, 4The Netherlands, Australia, Thailand Research Collaboration (HIV- NAT), Bangkok, Thailand, 5Department of Pediatrics, Chulalongkorn University, Bangkok, Thailand

929 T-Cell Senescence and CMV Positivity and Viremia Status in Perinatally HIV-Infected Children

Suad Kapetanovic1, Lisa Aaron1, Grace Montepiedra2, Andrea Kovaci3, 1National Institute of Mental Health, National Institutes of Health, Bethesda, MD, United States, 2School of Public Health, Harvard University, Boston, MA, United States, 3“Keck” School of Medicine, University of Southern California, Los Angeles, CA, United States

Session P-12 Poster Session

Thursday March 6, 2014, 2:30 PM–4:00 PM Exhibit Hall D

Outcomes Among Adolescents: Perinatally and Behaviorally Acquired HIV Infection

930 Outcomes of Perinatally HIV-Infected Adolescents On Antiretroviral Therapy in Southern Africa

Mary-An Davies1, Kathryn Stinson1, Karl Technau1,2,3, Sam Phiri4, Helen Rabei5, Maureen Wellington1, Janet Giddy6, Robin Wood6, Lynne Mofenson7, Harry Moutre8,9,10, for International Epidemiologic Databases to Evaluate AIDS Southern Africa (iDEA-SA)

1School of Public Health and Family Medicine, University of Cape Town, Cape Town, South Africa, 2Empilweni Services and Research Unit, Rahima Moosa Mother and Child Hospital, Johannesburg, South Africa, 3University of Witwatersrand, Johannesburg, South Africa, 4Lighthouse Trust Clinic, Lilongwe, Malawi, 5Tiberger Academic Hospital, University of Stellenbosch, Stellenbosch, South Africa, 6Newlands Clinic, Harare, Zimbabwe, 7McCord Hospital, Durban, South Africa, 8Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa, 9Gugulethu Community Health Centre, Cape Town, South Africa, 10Ernst Oppenheimer Shriver National Institute of Child Health and Human Development, Rockville, MD, United States, 11Wits Reproductive Health and HIV Institute, University of Witwatersrand, Johannesburg, South Africa, 12Harriet Shea Children’s Clinic, Chris Hanr Bangwathun Hospital, Soweto, South Africa

931 Greater Early CD4 Responses To CART Initiation Not Maintained for Non-Perinatal Youth

Allison Agwu1, Guy Mahiane1,2, Barong A. S. Nonyane1, Keri Althoff4, Baligh Yehia5, Stephen Berry2, Richard Rutstein1, Kelly A. Gebor5, for the HIV Research Network

1Pediatrics & Medicine, Division of Infectious Diseases, Johns Hopkins University School of Medicine, Baltimore, MD, United States, 2Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, 3Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, 4Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, United States, 5Department of Medicine, Division of Infectious Diseases, Johns Hopkins University School of Medicine, Baltimore, MD, United States, 6Department of Pediatrics, Children’s Hospital of Philadelphia, Philadelphia, PA, United States

932 Parental Absence From Clinic Predicts Virologic Failure in Adolescents in Botswana

Elizabeth Lowenthal1,2, Tafreyi Marukutira1, Oratile Tshume1, Jennifer Chapman1, Tebo Diposito1, Omphile Lepolisi1, Keboletse Mokete1, Jean Nachega2, Gabriel Anabwane1, Robert Gross1, 1Pediatrics and Epidemiology, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, United States, 2Children’s Hospital of Philadelphia, Philadelphia, PA, United States, 3Botswana-Baylor Children’s Clinical Centre of Excellence, Gaborone, Botswana, 4Stellenbosch University, Cape Town, South Africa, 5University of Pittsburgh, Pittsburgh, PA, United States, 6Medicine and Epidemiology, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, United States, 7Botswana-UPenn Partnership, Gaborone, Botswana

Session Posters
934 Factors Associated With Successful Retention Among Non-Perinatally HIV-Infected Youth

Charles Farmer1, Båligh Yehia2, Richard Rutstein3, Stephen Berry4, Kelly Gebo5, Allison Agwud6, for the HIV Research Network.

1Department of Medicine, Division of Infectious Diseases, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, United States; 2Division of General Pediatrics, Children’s Hospital of Philadelphia, Philadelphia, PA, United States; 3Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, United States; 4Department of Medicine, Division of Infectious Diseases, Johns Hopkins University School of Medicine, Baltimore, MD, United States; 5Departments of Pediatrics & Medicine, Division of Infectious Diseases, Johns Hopkins University School of Medicine, Baltimore, MD, United States; 6Dependents of Pediatrics & Medicine, Division of Infectious Diseases, Johns Hopkins University School of Medicine, Baltimore, MD, United States.

Session P-V1 Poster Session

Wednesday March 5, 2014, 2:30 pm–4:00 pm Exhibit Hall D

Pre-Clinical Studies of Microbicides

935 PCR as a Virological Endpoint for Testing Microbicidal Efficacy in the Colorectal Explant Model

Laura Janock1, Alexy Nikkorov1, Ian McGowan2

1University of Pittsburgh Medical Center, Pittsburgh, PA, United States; 2Medicine, University of Pittsburgh, Pittsburgh, PA, United States.

936 Irreversible Inactivation and Breakdown of HIV1 With Env-gp120 Targeting Peptide Triazole Thiois

Arrangassery Rosemary Bastian1, Lauren D. Bailey2, Diogo R. D. Moreira3, Kevin Freedman4, Karyn McFadden5, Caitlin Duffy2, Ali Emileh6, Jefferey Jacobson1, James A. Hoxie1, Irwin Chaiken2

1Biomedical Engineering and Sciences, Drexel University, Philadelphia, PA, United States; 2Biochemistry and Molecular Biology, Drexel University, Philadelphia, PA, United States; 3Department of Biomedical Engineering and Sciences, Federal University of Pernambuco, Recife-PE, Brazil; 4Department of Mechanical Engineering and Mechanics, Drexel University, Philadelphia, PA, United States; 5Department of Molecular Genetics and Microbiology, Duke University, Durham, NC, United States; 6School of Engineering, Dartmouth College, Hanover, NH, United States; 7Department of Medicine, Drexel University, Philadelphia, PA, United States; 8Immunology, University of Pennsylvania, Philadelphia, PA, United States.

937 Labyrinthinepeptin A1 Demonstrates Potent and Dual Anti-HSV and Anti-HIV Activity

Geoffrey Férit1, Mariya Petrova1, Graciela Andrei1, Robert Snoeck1, Jos Vanderleyden2, Roderich Süssmuth3, Mark Brönstrup1, Dominique Schols1

1Rega Institute, Leuven, Belgium; 2Centre of Microbial and Plant Genetics, Leuven, Belgium; 3Technische Universität Berlin, Berlin, Germany.

938 GSK1265744 Demonstrates Robust In Vitro Activity Against Various Clades of HIV-1

Sharon L. Karmon1, Hiroshi Mohri2, William Spreen3, Zhi Hong4, David Ho1, Martin Markowitz1

1Aaron Diamond AIDS Research Center, an affiliate of The Rockefeller University, New York, NY, United States; 2GlaxoSmithKline, Research Triangle Park, NC, United States.

Session P-V2 Poster Session

Wednesday March 5, 2014, 2:30 pm–4:00 pm Exhibit Hall D

Animal Models of Clinical Studies and PrEP

939 Does Tenofovir Gel After HIV Disease Progression in CAPRISA 004 Trial Seroconvertors?

Nigel J. Garrett1, Lise Werner2, Nivashree Naicker2, Thabile Mtshweni1, Vivek Narang13, Sengizewi Sibeke5, Natasha Samsunder5, Carolyn Williamson5, Quarraisha Abdool Karim3,4, Salim Abdool Karim3,4

1CAPRISA, Durban, South Africa; 2Institute of Infectious Diseases and Molecular Medicine & the Division of Medical Virology, Cape Town, South Africa; 3Columbia University, New York City, NY, United States.

940 Efficacy of Vaginal Gel Containing Tenofovir and Emtricitabine Against Rectal SHIV Transmission

Charles W. Dobard1, Natalia Makarova1, Roliera West1, Andrew Taylor1, Chuong Dinh2, Amy Martin3, James Mitchell4, Debra Hanson3, Chou-Pong Pau1, Wald Henne1

1HIV and prevention, Centers for Disease Control, atlanta, GA, United States; 2Quantine Sciences and Data Management Branch, Centers for Disease Control, atlanta, GA, United States.

941LB GSK1265744 Long-Acting Protects Macaques Against Repeated High-Dose Intravaginal Challenges

Chasity D. Andrews1, William R. Spreen2, Yun Lan Yueh3, Agegnehu Gettie4, Kasi Russell-Lodigiuq5, Hiroshi Mohri6, Cecilia Cheng-Mayer7, Zhi Hong8, David D. Ho1, Martin Markowitz9

1Aaron Diamond AIDS Research Center, New York, NY, United States; 2GlaxoSmithKline, Research Triangle Park, NC, United States; 3Tulane National Primate Research Center, Covington, LA, United States.

942 SHIV Infection Risk After Rectal Application of a Highly Osmolar Personal Lubricant

Sundaram A. Vishwanathan1, Monica Morris2, Charles Rose3, Richard J. Wolitski4, Lee Crescia5, Jenkins6, Sharon Ellis7, Michael Hendry8, Janet M. McNicholl8, Ellen N. Kersh9

1DHAP, CDC, Atlanta, GA, United States; 2Total Solutions, Atlanta, GA, United States.

943 Controlled Trial of an Internet-Based Risk Reduction Intervention in HIV+ Men Who Have Sex With Men

Joel Million1, Sonia Jain2, Eric Daar1, Michael Dubel3, Edward Seefried4, Eric Ellorin5, Gustavo A. Jimenez-Maggiora6, Sheldon R. Morris7, Richard H. Haubrich8, CCTG 592 Team

1University of Southern California Keck School of Medicine, Los Angeles, CA, United States; 2UC, San Diego, San Diego, CA, United States; 3Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA, United States.

944 Changes in the Contribution (PAR%) of STIs To HIV Acquisition Among Kenyan FSWs From 1993 To 2012

Linnet Masese1, Jared M. Baeten2, Barbira A. Richardson3, Susan M. Graham1, Elizabeth Bukusi2, Juma Shafi3, Walter Jaoko3, James Kiarie3, R. Scott McClelland1

1University of Washington, Seattle, WA, United States; 2KEMRI, Nairobi, Kenya; 3University of Nairobi, Nairobi, Kenya.

945 Intervention To Reduce HIV/STI Among High-Risk Patients in China: Cluster Randomized Trial

Don Operario1, Debin Wang2, Mei-Fen Yang3, Kathleen Blaney1, Jing Cheng4, Hong Qian5, Hongbo Zhang6, Gregory Szekeres7, Jerome Gailea1, Thomas Coates3

1School of Public Health, Brown University, Providence, RI, United States; 2Arth Medical University, Heifei, China; 3University of California Los Angeles, Los Angeles, CA, United States.
946 Validation of the Revised Denver HIV Risk Score Using a National HIV Testing Cohort

JASON HAUKOES1, EMILY HOPKINS2, MEGGAN BUCOSI3, MICHAEL LYONS4, RICHARD ROTHMAN4, DOUGLAS WHIT1, AILA AL-TAYYIB5, LUCY BRADLEY-SPRINGR1, ALLISON SABEL6, MARK THRUN7
1Emergency Medicine, Denver Health Medical Center, Denver, CO, United States; 2Emergency Medicine, University of Cincinnati, Cincinnati, OH, United States; 3Emergency Medicine, Johns Hopkins University, Baltimore, MD, United States; 4Emergency Medicine, University of Colorado School of Nursing, Aurora, CO, United States; 5Emergency Medicine, Highland Hospital, Oakland, CA, United States; 6Denver Public Health, Denver, CO, United States; 7University of Colorado School of Nursing, Aurora, CO, United States; 8Denver Health Medical Center, Denver, CO, United States

Session P-V4 Poster Session

Wednesday March 5, 2014, 2:30 pm–4:00 pm  Exhibit Hall D

947 Cost Effectiveness of Antiretrovirals in HIV Control in Rural Zambia: A Stochastic League Approach

BROOKE E. NICHOLS1, ROB BAULITTEN2, JANNEKE H. VAN DIJK3, PHIL E. THUMAS4, JAN L. NOUWER5, CHARLES A. B. BOUCHER6, DAVID A. M. C. VAN DE VIJVER7
1Viroscience, Erasmus Medical Center, Rotterdam, Netherlands; 2Primary and Community Care, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; 3Machine Mission Hospital and Macha Research Trust, Macha, Zambia; 4Medical Microbiology and Infectious Diseases, Erasmus Medical Center, Rotterdam, Netherlands

948 Darunavir(DR)/r-Based PEP Versus Standard of Care (SOC) – the Randomized PEPDar Study

GERD FÄTKENHEUER1, NORMA JUNG2, HEKO JENSEN3, ALBRECHT STOEHR1, KELKAWUS ARASTEH4, JOHANNES BOGNER5, CHRISTOPH STEPHANAN, CHRISTOPH D. SPINNER1, OLAF DEGEN6, BRITTA RANNEBERG7
1Med. Einrichtungen der Universität Köln, Cologne, Germany; 2Klinik f"ur Innere Medizin, Med. Christine E. Ross1, Guoyu Tao2, Karen W. Hoover2
1DSTDP, CDC, Atlanta, GA, United States, 2San Diego State University, San Diego, CA, United States

977 Measuring Late HIV Diagnosis Among Men Who Have Sex With Men: AIDS Diagnosis vs. Testing Frequency

David A. Katz3, Julia C. Dombrowski1, Amy Bennett2, Susan Buskin1, 2
1University of Washington, Seattle, WA, United States, 2Public Health - Seattle & King County, Seattle, WA, United States

978 Longitudinal Treatment Outcomes in HIV-Infected Prisoners and Influence of Re-Incarceration

Jaimie P. Moyer1,2, Javier Cepeda1, Johnny Wu3, Robert L. Trestman1, Frederick L. Atlee1, Sandra A. Springer1
1Medicine, Yale University School of Medicine, New Haven, CT, United States, 2Chronic Disease Epidemiology, Yale University School of Public Health, New Haven, CT, United States, 3Epidemiology of Memorrhagic Diseases, Yale University School of Public Health, New Haven, CT, United States

979 Impression Among a Large US Clinical Cohort of HIV-Positive Outpatients

David L. Rosen1, Carol E. Golin1, Catherine A. Grodensky1, Samuel Stinnett2, Becky L. White1, Sonia Napravnik1, David A. Wolff1
1Institute for Global Health and Infectious Diseases, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 2Medicine and Health Behavior, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

980 Using HIV Surveillance Registry Data To Re-Link Patients To Care: The RSVP Project in San Francisco

Kate A. Buchacz1, Lorena Espinoza2, asphalt Chen1, Maree Kay Parisi1, Maya Yoshida1, Erin Antunez2, Viva Delgado2, Nicholas J. Moss1, Susan Scheer1
1Centers for Disease Control and Prevention, Atlanta, GA, United States, 2San Francisco Department of Public Health, San Francisco, CA, United States

981 A Surveillance-Based Risk Scoring Tool To Prioritize Cases for HIV Care Re-Linkage Efforts

Julia C. Dombrowski1, James P. Hughes1, Amanda A. Castelli1, Kathleen A. Brady2, Susan Buskin1, Amy Bennett2, Matthew R. Golden1
1University of Washington, Seattle, WA, United States, 2Medicine - Seattle & King County, Seattle, WA, United States

982 Beyond Core Indicators of Retention in HIV Care: Added Prognostic Value of Missed Clinic Visits

Michael J. Mugavero1, Andrew O. Westfall1, Elvin Geng1, Stephen R. Cole1, Heidi M. Crane1, Mari M. Kitahata2, W. Christopher Mathews1, Sonia Napravnik1, James L. Raper1, 3CFAR Network of Integrated Clinical Systems (CNICS)
1Medicine, University of Alabama at Birmingham, Birmingham, AL, United States, 2Medicine, University of California San Francisco, San Francisco, CA, United States

983 National ART Monitoring System Enables Robust Transfer-Adjusted Retention Analyses in Namibia

Anna Jonas1, 2Andrew Maher1, Ray W. Shnairish, Michael de Klerk1, Francina Kainjipe-Tjikuta1, Gram Mutand01, Sadhna V. Patel2, Anne-Marie Nitschke1, Alexineh Mualukhotamb1, David W. Lowrance2
1Institute for Global Health and Infectious Diseases, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 2Medicine, University of Washington, Seattle, WA, United States

984 Migration After HIV Diagnosis, United States

Lorena Espinoza2, Irene Hall, Aruna Surendra Babu, Tian Tang, Mi Chen
1Division of HIV/AIDS Prevention, CDC, Atlanta, GA, United States

985 Early Linkage To HIV Care and Antiretroviral Therapy Use Among MSM — 20 US Cities, 2008 and 2011

Brooke Houts1, Teresa Finlayson, Cyprian Wejnert, Gabriela Paz-Bailey for the NHBS Study Group
1CDC, Atlanta, GA, United States

986 The Impact of Opioid Substitution Treatment On Highly Active Antiretroviral Treatment Adherence

Bohdan Nosyk1, Jeong Min, Viviane Lima, Guillaume Colley, Benita Yip, Evan Wood, Julio Montaner1
1BC Centre for Excellence in HIV/AIDS, Vancouver, BC, Canada
988 Correlation Between Community Variables and HIV Linkage To Care and Viral Suppression, Atlanta, GA
Neela D. Goswami1,2, Sharoda Dasgupta3, Patrick Sullivan4, Deepali Rane4, Carlos del Rio5,6, Travis Sanchez7
1Medicine, Emory University School of Medicine, Atlanta, GA, United States, 2Emory University Rollins School of Public Health, Atlanta, GA, United States, 3Georgia Department of Public Health, Atlanta, GA, United States

Session P-W3 Poster Session
Tuesday March 4, 2014, 2:30 pm–4:00 pm Exhibit Hall D
Cascade of Care, Community Viral Load, and Viral Suppression

989 Viral Suppression Among Foreign-Born HIV-Infected Persons in the United States
Tanya R. Myers1,2, Jacky Skarbinski1
1CDC, Atlanta, GA, United States, 2LSHTM, London, United Kingdom

990 Mapping Community Viral Load and Transmission Potential Prevalence of HIV Among MSM in New York City
Hong Van Trui1, Vijay Nand1, James E. Eglin2, Victoria Frye2, Donald R. Hoover3, Eduardo Baz3, Debbie Lucy4, Magdalena Cerda5, Danielle C. Ompad6, Beryl A. Koblin7

Session P-W6 Poster Session
Wednesday March 5, 2014, 2:30 pm–4:00 pm

1005 Independent Evaluation of Predicate Incidence Assays for HIV Surveillance
Reshma Kassanjee1, Christopher Pelcher2, Sheila Keating2, Shelley Facente2, Matt Price2, Jeffrey Martin3, Susan Little4, Alex Welte5, Michael Busch6, Gary Murphy7, Consortium for the Evaluation and Performance of HIV Incidence Assays (CEPIA)
1The South African DST/NRF Centre of Excellence in Epidemiological Modelling and Analysis (SACEMSA), Stellenbosch University, Stellenbosch, South Africa, 2University of California San Francisco, San Francisco, CA, United States, 3Blood Systems Research Institute, San Francisco, CA, United States, 4Department of Medical Affairs, International AIDS Vaccine Initiative (IAVI), New York City, NY, United States, 5Department of Medicine, University of California San Diego, La Jolla, CA, United States, 6Health England Public, London, United Kingdom

1006 Performance of the Limiting Antigen–Avidity EIA for Use With Dried Blood Spot Specimens
Erin K. Rottinghaus, Trudy Dobbs, Bhart S. Parekh, Yen T. Duong, Centers for Disease Control and Prevention, Atlanta, GA, United States

1007 The Impact of HIV Subtype On Specificity of Cross-Sectional HIV Incidence Assays in Rakai, Uganda
Andrew F. Longosz1, 2, David Serwadda2, 3, Fred Nalugoda4, Godfrey Kigozi5, Veronica Franco6, Ronald H. Gray7, 8, Thomas C. Quinn9, 10, Susan H. Eshleman11, Oliver Laeyendecker12, 13
1NAID, National Institutes of Health, Baltimore, MD, United States, 2Makere University School of Public Health, Kampala, Uganda, 3Rakai Health Sciences Program, Rakai, Uganda, 4The Johns Hopkins University School of Medicine, Baltimore, MD, United States, 5The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

1008 Incorrect Identification of Recent HIV Infection Using a Lag-Avidity Assay in Adults in the US
Andrew F. Longosz1, 2, Ron Brookmeyer3, Shruti Mehta4, Greg D. Kirk5, Joseph B. Margolick6, Joelle Brown7, Thomas C. Quinn8, 9, Susan H. Eshleman10, Oliver Laeyendecker11, 12
1Laboratory of Immunoregulation, Division of Intramural Research, National Institutes of Health, Bethesda, MD, United States, 2Prevention Division, Public Health, Seattle & King County, Seattle, WA, United States, 3Epidemiology Department, University of Washington, Seattle, WA, United States, 4Department of Medicine, University of Washington, Seattle, WA, United States, 5Department of Pathology, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, 6Department of Epidemiology, The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, 7Department of Molecular Microbiology and Immunology, The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, 8Department of Epidemiology, University of California Los Angeles, Los Angeles, CA, United States, 9Department of Medicine, The Johns Hopkins University School of Medicine, Baltimore, MD, United States

Session P-W7 Poster Session
Thursday March 6, 2014, 2:30 pm–4:00 pm

1009 Increasing Viral Suppression and Declining HIV/AIDS and Mortality in the Era of Expanded Treatment
Susan E. Buskin1, 4, Amy B. Bennett5, Julia C. Dombrowski6, 7, Matthew R. Golden7, 8
1Prevention Division, Public Health, Seattle & King County, Seattle, WA, United States, 2Epidemiology Department, University of Washington, Seattle, WA, United States, 3Department of Medicine, University of Washington, Seattle, WA, United States, 4Project San Francisco, San Francisco, CA, United States, 5Blood Systems Research Institute, San Francisco, CA, United States, 6Blood Systems Research Institute, San Francisco, CA, United States, 7Department of Medicine, University of California at San Francisco, San Francisco, CA, United States, 8Project San Francisco, San Francisco, CA, United States

1010 BMI and CD4+ T-Cell Recovery at 12 Months Among Adults Initiating ART in the United States and Canada
John R. Koethe1, Cathy Jenkins2, Bryan Lau3, Bryan E. Shephard4, Michael J. Silverberg5, Aaron J. Blashill6, Aranka Anerma7, Amanda Willig8, Samuel E. Stinnette9, Timothy R. Sterling3, North American AIDS Cohort Collaboration on Research and Design (NA-ACCORD)
1Infectious Diseases, Vanderbilt University, Nashville, TN, United States, 2Biostatistics, Vanderbilt University, Nashville, TN, United States, 3Infectious Diseases, Johns Hopkins University, Baltimore, MD, United States, 4Kaiser Permanente Northern California, Oakland, CA, United States, 5Harvard University, Boston, MA, United States, 6British Columbia Centre For Excellence in HIV/AIDS, Vancouver, BC, Canada, 7University of Alabama at Birmingham, Birmingham, AL, United States, 8University of North Carolina, Chapel Hill, NC, United States

1011 Impact of Smoking On Life Expectancy Among HIV-Infected Individuals: The ART Cohort Collaboration
Marie Helleberg1, Margaret T. May2, Jonathan A. C. Sterne3, Niels Oebel4, for the ART-CC
1Department of Infectious Diseases, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark, 2School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom

1012 Standardized Mortality Ratios Among Drug Users in Amsterdam Differ by HCV and HIV Infection Status
Daniaela K. van Santen1, Jannie J. J. van der Helm2, Bart P. X. Grady3, 4, Anneke S. de Vos3, Mirjam E. E. Kretzschmar5, 6, Ineke G. Stolte5, 6
1Research, Public Health Service of Amsterdam, Amsterdam, Netherlands, 2Center for Infection and Immunology Amsterdam (CINIMA), Academic Medical Center (AMC), Amsterdam, Netherlands, 3University Medical Center Utrecht, Julius Centrum, Utrecht, Netherlands, 4Center for Infectious Disease Control, National Institute of Public Health and the Environment, Bilthoven, Netherlands

1013 Prognostic Value of the VACS Index for Mortality in British Columbia, Canada
Angela Cescon1, Mark Hull2, Wendy Zhang3, Thomas Roston4, Susan Shurgold5, Guillaume Colley5, Viviane D. Lima6, 7, P. Richard Harrigan7, 8, Julio S. G. Montaner1, 9, Robert S. Hogg1, 9
1BC Centre for Excellence in HIV/AIDS, Vancouver, BC, Canada, 2University of British Columbia, Vancouver, BC, Canada, 3Simon Fraser University, Burnaby, BC, Canada

1014 Impact of Low-Level Viremia On Clinical and Virological Outcomes in Treated HIV Infected Patients
Marie-Anne Vandenhende1, Suzanne Ingle2, Margaret May3, Matthias Cavasini4, Amanda Mocrott5, Peter Reiss6, Janet Tate7, Heidi Crane7, Jonathan Sterne8, Genevieve Châline9, on behalf of the Antiretroviral Therapy Cohort Collaboration (ART-CC)
1Epidémiologie-Biostatistique, Université Bordeaux, Centre INSERM U897, ISPED, Bordeaux, France, 2School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom, 3Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland, 4Research Department of Infection and Population Health, UCL Medical School, London, United Kingdom, 5Academic Medical Center, Amsterdam Institute of Global Health and Development, Amsterdam, Netherlands, 6Yale University School Of Medicine, VA Connecticut Healthcare System, New Haven, CT, United States, 7Center for AIDS Research; University of Washington, Seattle, WA, United States
1015 Increase in HIV Plasma Viral Load Set-Point Among UK MSM

Victoria Parsons1,2, Andrew Phillips1, Richard Gilson2, Sarah Fidler2, Martin Fisher3, Anne Johnson3, David Hawkins3, Ken McLean3, Margaret Johnson3, Khouloud Porter3, for the UK Register of HIV Serocounters
1MRC Clinical Trials Unit at UCL, London, United Kingdom, 2University College London, London, United Kingdom, 3Imperial College London, London, United Kingdom, 4Brighton & Sussex Medical School, Brighton, United Kingdom, 5Chelsea & Westminster NHS Foundation Trust, London, United Kingdom, 6West London Centre for Sexual Health, London, United Kingdom, 7Royal Free London NHS Foundation Trust, London, United Kingdom

Session P-W8 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM Exhibit Hall D

Co-Morbidities

1016 HIV, Non-Communicable Chronic Diseases and Associated Factors in Tanzania and Uganda

Saidi H. Kapiga1, Kathy Baisely4, Samuel Biraro1, Bazli Baltazar1, Fiona Ewing1, Hashim Ramadhani1, Robert Peck4, Richard Hayes2, Paula Munderi2, Heiner Grosskurth1
1Infectious Disease Epidemiology, London School of Public Health, Mwanza, Tanzania, United Republic of, 2Infectious Disease Epidemiology, London School of Public Health, Mwanza, United Kingdom, 3MRC/UVRI Uganda Research Unit on AIDS, Entebbe, Uganda, 4Mwanza Intervention Trials Unit, Mwanza, Tanzania, United Republic of, 5Bugando Medical Centre, Mwanza, Tanzania, United Republic of, 6Infectious Disease Epidemiology, London School of Public Health, London, United Kingdom

1017 Female Partner Bacterial Vaginosis and the Penis Microbiota: Rakai, Uganda

Cindy Liu1, Bruce Hungate1, Aaron Tobian2, Jacques Ravel3, Jessica Proctor1, David Servadda3, Fred Nalugoda4, Maria Wawer5, Ronald Gray3, Lance Price1
1Department of Pathology, Johns Hopkins School of Medicine, Baltimore, MD, United States, 2Department of Biological Sciences, Northern Arizona University, Flagstaff, AZ, United States, 3Institute for Genome Sciences, Baltimore, MD, United States, 4Department of Medicine, University of Toronto, Toronto, ON, Canada, 5Rakai Health Sciences Program, Entebbe, Uganda, 6Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, 7Translational Genomics Research Institute, Flagstaff, AZ, United States

1018 Low Viral Suppression and High HIV Diagnosis Rate Among MSM With Syphilis - Baltimore, Maryland

Laura A. Cooley1, Marcia L. Pearl1, Colin Flynn1, David S. Byth2, Christine Ross1, Geoffrey Hart-Cooper4, James Morgan5, Alexandria M. Oster1
1Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, GA, United States, 2Department of Biological Sciences, Northern Arizona University, Flagstaff, AZ, United States, 3Institute for Genome Sciences, Baltimore, MD, United States, 4Division of STD Prevention, Centers for Disease Control and Prevention, Atlanta, GA, United States, 5Baltimore County Department of Health and Human Services, Baltimore, MD, United States

1019 Trends in Comorbid Conditions Mentioned With HIV Disease On Death Certificates, US, 2000-2010

Kpandja Djawe1, Kate Buczacz1, Charles E. Rose1, John T. Brooks1
Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Epidemiology Branch, Atlanta, GA, United States

1020 The Association Between HPV and HIV Shedding in Vaginal and Anorectal Specimens

Julia Hood1, Geoffrey Gottlieb2, Papa Salif Sow1, Macoumba Toure3, Qinghua Feng1, Nancy Kiviat1, Stephen Hayes5
1Epidemiology, University of Washington, Seattle, WA, United States, 2Medicine, University of Washington, Seattle, WA, United States, 3Infectious Disease, University of Dakar, Dakar, Senegal, 4Pathology, University of Washington, Seattle, WA, United States, 5Epidemiology, Global Health, University of Washington, Seattle, WA, United States

1021 Incidence of Sexually Transmitted Diseases Among Persons With HIV, New York City, 2000-2010

Sarah L. Braunstein1, Preeti Pathela2, Laura Kersanske1, Colin Shepard2
1Bureau of HIV/AIDS Prevention and Control, New York City Department of Health and Mental Hygiene, Queens, NY, United States, 2Bureau of STD Control, New York City Department of Health and Mental Hygiene, Queens, NY, United States

1022 Increasing Rates of STI Are Linked To Reduced Condom Use in Patients With Primary HIV-1 Infection

Dominique L. Braun1, Roger Kouyos2, Rafahl Ghenz3, Christina Grube1, Rainer Weber1, Huldrych Günthard1
1Division of Infectious Diseases and Hospital Epidemiology, University Hospital Zurich, Zurich, Switzerland

1023 Does Substance Use Compromise Depression Treatment? A Randomized Trial of Homeless HIV+ Persons

David J. Grelotti1,2, Gwendolyn H Hamner1, James W. Dilley3, Dan H. Karasic4, James L. Sorensen5,6, Alexander C. Tsai7
1Department of Epidemiology, Harvard School of Public Health, Boston, MA, United States, 2Department of Psychiatry, Massachusetts General Hospital, Boston, MA, United States, 3Division of Communicable Disease Control, Communicable Disease Emergency Response Branch, California Department of Public Health, Richmond, CA, United States, 4Department of Psychiatry, University of California San Francisco, San Francisco, CA, United States, 5Department of Medicine and MGH Center for Global Health, Massachusetts General Hospital and Harvard Medical School, Boston, MA, United States, 6Ragon Institute of MGH, MIT, and Harvard, Boston, MA, United States, 7Department of Psychiatry and MGH Center for Global Health, Massachusetts General Hospital and Harvard Medical School, Boston, MA, United States

Session P-W9 Poster Session
Thursday March 6, 2014, 2:30 PM–4:00 PM Exhibit Hall D

Transmission/Risk Factors

George Githuka1, Wolfgang Hladik2, Samuel Mwalili3, Davies Kinanga1, Mamo Umuro1, Mercy Muthui1, Joshua Gitonga1, William Maina1, Andrea A. Kim1

1025 HIV Incidence in Rural Western Kenya Using Longitudinal Analysis From Home-Based HIV Testing

Lisa A. Mills1,2,3, George Olillo1, Manase Amoth2, Daniel Kwaro1, Victor Saempi1, Frederik Ottero3, Maquins Sewe3, John Williamson4, Kayla Laserson3
1Centers for Disease Control and Prevention, Kisumu, Kenya, 2Kenya Medical Research Institute/Centers for Disease Control and Prevention Research and Public Health Collaboration, Kisumu, Kenya

1026 Temporal Trends in HIV-1 Incidence and Risk Behaviors Among MSM, Bangkok, Thailand, 2006-2013

Timothy H. Holtz1,2, Philip A. Mock1, Warunee Thienkrua1, Wannee Chonwattana3, Wipas Wimonsate1, Supaporn Chaikummao1, Wichuda Sukwicha1, Anupong Chitrvaryakorn2, Marcel E. Cullin3,4
1HIV/AIDS Research Program, Thailand MOHP - US CDC Collaboration, Nonthaburi, Thailand, 2Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, GA, United States, 3Department of Disease Control and Prevention, Atlanta, GA, United States, 4Department of AIDS Research, Emory University, New York, NY, United States

1027 The Potential Impact of Targeting Prevention Strategies To HIV-Discordant Households

Ruth Emerson1, Deborah Donnell1, George Bicego1, Khanya Mabuza2, Stephanie Hellingier1, Jessica Justman
1Statistical Center for HIV/AIDS Research & Prevention, Fred Hutchinson Cancer Research Center, Seattle, WA, United States, 2Centers for Disease Control and Prevention, Atlanta, GA, United States, 3National Emergency-Response Council on HIV and AIDS, Kingdom of Swaziland, Marozini, Swaziland, 4Department of Population and Family Health, Mailman School of Public Health, Columbia University, New York, NY, United States, 5CAP-Columbia, Mailman School of Public Health, Columbia University, New York, NY, United States

1028 The Effect of Sexually Transmitted Infections On HIV Incidence Among MSM in Atlanta, GA

Colleen F. Kelley1, Adam S. Vaughan1, Nicole Luisi2, Travis Sanchez1, Paula Frew1, Carlos del Rio1, Patrick S. Sullivan1, Eli S. Rosenberg1
1Center for AIDS Research, Emory University, Atlanta, GA, United States
1029 Factors Associated With HIV Discordance Among Couples in Kenya: Results From a Population Survey
Wanjiru Waruru1, Agneta Mbithi2, Anthony Waruru2, Jennifer Galbraith3, Timothy A. Kellogg4, Scott Epperson5, Anne Ng’ang’a6, Sophie Mwanyambai6, Lucy Kimoondo6, Andrea A. Kim7
1University of California, San Francisco, Nairobi, Kenya, 2National AIDS and STI Control Programme, Nairobi, Kenya, 3Centers for Disease Control and Prevention, Nairobi, Kenya, 4Centers for Disease Control and Prevention, Atlanta, GA, United States, 5National Public Health Laboratory Services, Nairobi, Kenya, 6National Council for Population and Development, Nairobi, Kenya

1030 Partners of Individuals With Acute HIV Infection Have a High Frequency of Known HIV Infection
Philip J. Peters1, Emily Westheimer1, Stephanie Cohen1, Charles E. Rose1, Cynthia L. Gay2, Charles Fann3, Steve Beagle2,4, Kate Washburn2, Tonyka L. Jackson1,4, Lisa H. Hightow-Weidman1
1Centers for Disease Control and Prevention, Atlanta, GA, United States, 2New York City Department of Health & Mental Hygiene, New York City, NY, United States, 3San Francisco Department of Public Health, San Francisco, CA, United States, 4University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 5North Carolina Department of Health and Human Services, Raleigh, NC, United States, 6ICF International, Atlanta, GA, United States

1031 Baseline Predictors of HIV-1 Acquisition Among Women Participating in MTN-003 (VOICE)
Gonasaagrie Nair1, Jennifer E. Bakaus1,2, Jeanne M. Marrazzo1, Gita Ramjee1, Tresia Palai1, Banini Akoto3, Clemencia Nakubulula3, Martinhette Taljaard4, Kailazaid Gomo5, Zvavanhera M. Chirera6,7
1CAPRISA/DDRMI, Nelson R Mandela School of Medicine, Durban, South Africa, 2Centers for Disease Control and Prevention, Atlanta, GA, United States, 3South African Medical Research Council, Durban, South Africa, 4University of Wolverhampton, Wolverhampton, South Africa, 5Chris Hani Baragwanath Hospital, Johannesburg, South Africa, 6Makerere University, Kampala, Uganda, 7The Aurum Institute, Klerksdorp, South Africa, 8HFH360, Durham, NC, United States, 9UCU, Harare, Zimbabwe

1032 Measuring Purposefully Adopted Seroadaptive Behaviors vs Reported Sexual Behaviors Among MSM
Christine M. Khosropour1, Julia C. Dombrowski2,3, James P. Hughes1, Lisa E. Manhart1, Jane M. Simonii1, Matthew R. Goldem1
1Epidemiology, University of Washington, Seattle, WA, United States, 2Medicine, University of Washington, Seattle, WA, United States, 3Public Health - Seattle & King County, Seattle, WA, United States, 4Biostatistics, University of Washington, Seattle, WA, United States, 5Psychology, University of Washington, Seattle, WA, United States

1033 Prevalence and Predictors of HIV Disclosure Among Adults Receiving Care in the United States
Christine L. Mattson1, Mark S. Freedman1, Linda Beer2, Patrick Sullivan1, Jacek Skarbinski3
1Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, GA, United States, 2Emory University, Atlanta, GA, United States

Andrew J. Mitsch1, H. I. Hall2, Amy L. Lansky1, Aruna Surendera-Babu2
1National Center for HIV, STD, Tuberculosis, and Viral Hepatitis Prevention, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, 2Macro International, Inc., Atlanta, GA, United States

1035 An Emerging HIV Epidemic Among Injection Drug User Networks During Austerity in Athens, Greece
Ashley Tsang1, John Schneider2, Vana Sympa3, Georgios Nikolopoulos3, Dimitrios Paraskevis4, Samuel Friedman1, Angelos Hatziakis2
1University of Chicago, Chicago, IL, United States, 2Department of Medicine, University of Chicago, Chicago, IL, United States, 3National Retrospective Reference Center, Athens, Greece, 4Hellenic Center for Disease Control and Prevention, Athens, Greece

1036 High HIV Prevalence Among Injection Drug Users in India: Women Bear a Disproportionate Burden
Gregory M. Lucas1, Sunil S. Solomon2,3, Aylak K. Srikrishnan2, Syed H. Iqbal1, Oliver Laeyendecker1, Allison McFall1, Munirathnam S. Kumar1, David D. Colɛntano1, Sunil S. Solomon2
1Johns Hopkins University School of Medicine, Baltimore, MD, United States, 2YR Gaitonde Centre for AIDS Research and Education, Chennai, India, 3National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, 4Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

1037 HIV Prevalence Among Women Who Inject Drugs and Exchange Sex for Money or Drugs: 20 US Cities, 2009
Lina M. C. Nerlander1, Kristen L. Hess, Ditte Broz2, Binh C. Le3, Caitlin Sonean1, Charles E. Rose4, Gabriela Paz-Bailey2, for the NHBIS Group
1Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, GA, United States

1038 Erectile Dysfunction Medication Use Associated With Unprotected Intercourse in HIV-Infected MSM
Xia Lin1, Christine L. Mattson1, Mark S. Freedman2, Jacek Skarbinski3, Centers for Disease Control and Prevention, Atlanta, GA, United States

1039 A Novel Analytical Approach Confirms Stabilization of HIV Epidemic in Pregnant Women in Namibia
Anna Jonas1, Steven Gutreuter2, Sadhana V. Patel1, Andrew Maher2, Michael de Klerk1, Tulli Nakanyala3, Francina Kaindje-Tjikutka3, Elia Shihepo4, David W. Lowrance5
1Ministry of Health and Social Services, Windhoek, Namibia, 2US Centers for Disease Control and Prevention, Atlanta, GA, United States, 3US Centers for Disease Control and Prevention, Windhoek, Namibia

1040 Viral Load Strategy: Impact On Risk Behavior and Serocombination of MSM in Specialized Care
Elisabeth Kuhn1, Anja Pottroff1,2, Henriëtte Dirks1, René Borgmann1, Michael Wolter1, Stefan Esser1, Norbert Schieber3,4, Norbert H. Brockmeyer1,2
1Clinic for Dermatology, Venereology and Allergology of the Ruhr-Universität Bochum, Bochum, Germany, 2Competence Network HIV/AIDS, Bochum/Essen, Germany, 3Department of Psychiatry and Psychotherapy, LVR-Klinikum Essen, Hospital of the University of Duisburg-Essen, Essen, Germany, 4Department of Dermatology and Venereology, University Hospital Duisburg-Essen, Essen, Germany

1041 Transmission Rates and Not Sexual Contact Patterns Drive HIV Epidemic Intensity in Africa
Steve E. Bellan1, Jonathan Dushoff2, Steven Gutreuter3, Alison P. Galvani1, Lauren A. Meyers2
1Center for Computational Biology and Bioinformatics, University of Texas at Austin, TX, United States, 2Biological, McMaster University, Hamilton, ON, Canada, 3Department of Mathematics and Statistics, McMaster University, Hamilton, ON, Canada, 4School of Medicine, Yale University, New Haven, CT, United States, 5Integrative Biology, University of Texas at Austin, TX, United States

Session P-X1 Poster Session
Tuesday March 4, 2014, 2:30 pm–4:00 pm Exhibit Hall D
HIV Testing in Low Income Settings

1042 Community-Based Integrated Family Planning and HIV Testing and Counseling Services in Uganda
Aurelie Brunel2, Patricia Wamala-Mucherzi, Jane Harriet Namwebya3, Tricia Petruney4, Vincent J. Wong3, Benson Tunwegise4, Sarah Mercer5, Victor Draman Allyo6, Angela Akol7
2FHI 360, Washington, DC, United States, 3Clinton Health Access Initiative, Kampala, Uganda, 4FHI 360, Kampala, Uganda, 5FHI 360, Durham, NC, United States, 6Office of HIV/AIDS, USAID, 1200 Pennsylvania Ave, DC, United States, 7National HTC Coordinator, Ugandan Ministry of Health, Kampala, Uganda

1043 HTC Campaign in Households Reached the Majority of Women But Only 50% of Men in Botswana Community
Vlad Novitsky1, Hermann Bussmann2, Sikhulile Moyo3, Erik van Widenfelt4, Mompaki Mmalane1, Quanhong Lei1, Joseph Makhem4, Shahin Lockman3, Victor DeGruttola5, Max Essex1
1Immunology & Infectious Diseases, Harvard School of Public Health, Boston, MA, United States, 2Botswana-Harvard AIDS Institute Partnership, Gabonorte, Botswana, 3Department of Biostatistics, Harvard School of Public Health, Boston, MA, United States

1044 Implementation of Routine, Opt-Out HIV Testing Does Not Increase Loss To Follow-up
Kate Clouse1, Colleen Hanrahan1, Jane Bassett2, Nandini Gangaule3, Linda Malijek1, Sandra Mokonyane4, Iain Sarine5, Annelies Van Riel6
1Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 2Witkoppen Health and Welfare Centre, Johannesburg, South Africa, 3Right to Care, Johannesburg, South Africa

1045 Assessment of the Potential Cost-Effectiveness of HIV Self-Testing in Resource Limited Settings
Valentina Cambiano, Debbie Ford, Travor Mbabu, Sue Naplerala, Mavedzenge, Alec Miners, Owen Mugurungi, Fumio Nakagawa, Paul Rentw, Andrew Phillips

1UCL, London, United Kingdom, 2Medical Research Council Clinical Trials Unit, London, United Kingdom, 3University of Zimbabwe Clinical Research Centre, Harare, Zimbabwe, 4RTI International, San Francisco, CA, United States, 5London School of Hygiene and Tropical Medicine, London, United Kingdom, 6Ministry of Health and Child Welfare Zimbabwe, Harare, Zimbabwe, 7University of York, York, United Kingdom

Session P-X2 Poster Session
Tuesday March 4, 2014, 2:30 pm–4:00 pm Exhibit Hall D

HIV Treatment and Care

1046 Treatment Outcomes Before and After the Decentralization of ART in an Urban Setting in Mozambique
Jan Walter, Marie-Luce Tombo, Celeste Gracia Edwards, Johnny Lujan, Annick Antierens, Lucas Moffino

1Médecins sans Frontières, Maputo, Mozambique, 2Médecins sans Frontières, Geneva, Switzerland

1047 CD4 Count at ART Initiation and Economic Restoration in Rural Uganda
Atteendar Venkataramani, Harsha Thirumurthy, Jessica Haberer, Yap Boum, Mark Siedner, Arnet Kembabazi, Peter Hunt, Jeffrey Martin, David Bangsberg, Alexander Tsai

1Department of Medicine and Center for Global Health, Massachusetts General Hospital, Boston, MA, United States, 2Department of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 3Epicentre, MSF, Mbarara, Uganda, 4Department of Medicine, Massachusetts General Hospital, Boston, MA, United States, 5Mbarara University of Science and Technology, Mbarara, Uganda, 6University of California San Francisco, San Francisco, CA, United States, 7Massachusetts General Hospital, Boston, MA, United States, 8Department of Psychiatry and Center for Global Health, Massachusetts General Hospital, Boston, MA, United States

1048 48-Week Outcomes in Adults Starting ART at CD4>350 Using Streamlined Care in Rural Uganda
Vivek Jain, Dathan M. Byonanebye, Gideon Amanyire, Douglas Black, James Rooney, Gabriel Chamie, Elvin H. Geng, Edwin D. Charlebois, Moses R. Kamya, Diane V. Havlir

1HIV/AIDS Division, University of California, San Francisco, San Francisco, CA, United States, 2Makere University College of Health Sciences, Kampala, Uganda, 3Gilead Sciences, Inc., Foster City, CA, United States

1049 Second-Line Failure and Protease Inhibitor Resistance in a Clinic in Johannesburg, South Africa
Rebecca H. Berhanu, Denise Evans, Prudence Iwe, David Spencer, Cindy Firthhaber, Ian Sann, Matthew P. Fox

1Focal Point, Right to Care, Johannesburg, South Africa, 2Health Economics and Epidemiology Research Office, University of the Witwatersrand, Johannesburg, South Africa, 3Clinical HIV Research Unit, University of the Witwatersrand, Johannesburg, South Africa, 4Helen Joseph Hospital, University of the Witwatersrand, Johannesburg, South Africa, 5Center for Global Health and Development Department of Epidemiology, Boston University, Boston, MA, United States

1050 A 5-Year Comparison of Viral Load and CD4 Cell Count Monitoring for ART Patients in Rural Uganda
Jonathan Wangisi, Paul Ekwaru, Stephen Okoboi, James Campbell, Rachel King, Aggrey Egesa, Celestin Bakanda, Emmy Muramuzi, Frank Kaharuna, Sam Malamba, David M. Moore

1The AIDS Support Organisation, Kampala, Uganda, 2University of Alberta, Edmonton, AB, Canada, 3University of Maryland, Baltimore, MD, United States, 4University of California San Francisco, San Francisco, CA, United States, 5Makere University School of Public Health, Kampala, Uganda, 6Makere University, Kampala, Uganda, 7BC Centre for Excellence in HIV/AIDS, Vancouver, BC, Canada, 8University of British Columbia, Vancouver, BC, Canada

1051 Success of Transfer of HIV Care From a PEPFAR Site To Community-Based Clinics in South Africa
Christie Coetze, Susan Regan, Janet Giddy, Tessa Gveynder, Melanie R. Gaynes, Kenneth A. Freedberg, Jeffrey N. Katz, Rochelle P. Walensky, Elena Losina, Ingrid V. Bassett

1McCook Hospital, Durban, South Africa, 2Massachusetts General Hospital, Department of General Medicine, Boston, MA, United States, 3Massachusetts General Hospital, Medical Practice Evaluation Center, Boston, MA, United States, 4Brigham and Women’s Hospital, Department of Orthopedic Surgery, Boston, MA, United States, 5Brigham and Women’s Hospital, Division of Rheumatology, Boston, MA, United States, 6Division of Infectious Diseases, Massachusetts General Hospital, Boston, MA, United States, 7Boston University School of Public Health, Departments of Biostatistics and Epidemiology, Boston, MA, United States, 8Division of Infectious Disease, Massachusetts General Hospital, Boston, MA, United States

1052 The Feasibility and Economic Impact of Time Designated Appointment System in a Busy HIV Care Clinic
Zachary A. Kwena, Betty Njoroge, Patrick Oyar, Craig R. Cohen, Elizabeth A. Bukusi

1Center for Microbiology Research, Kenya Medical Research Institute, Kisumu, Kenya, 2Center for Microbiology Research, Kenya Medical Research Institute, Nairobi, Kenya, 3Ob/Gyn & RS, University of California, San Francisco, San Francisco, CA, United States

1053 Long-Term Virologic Response in a Cohort of HIV-Infected Patients in South Africa
Kate Shearer, Alana T. Brennan, Mhari Skew, Rebecca Berharu, Lawrence Long, Matthew Fox

1Health Economics and Epidemiology Research Office, Johannesburg, South Africa, 2Center for Global Health & Development, Boston, MA, United States, 3Right to Care, Johannesburg, South Africa

1054 CD4 Cell Decline and Time To Reaching ART Eligibility in HIV Patients From Rwanda
Chloe A. Teasdale, Allison Zerbe, Veronica Mugisha, Ruben Sahabo, Elaine J. Abrams, Wafa M. El-Sadr, for Identifying Optimal Models of HIV Care in Africa Study

ICAP, Columbia University, New York, NY, United States

1055 Predictors of Late Engagement To HIV Care in Western Kenya: A Cross-Sectional Study
Charles M. Kwobah, Paula Braitsstein, Julius Koech, Gilbert Simiyu, Ann W. Mwangi, K. A. Wools-Kaloustian, Abraham Sikwa

1Medicine, Moi University Clinical Research Centre, Eldoret, Kenya, 2Academic Model Providing Access to Healthcare, Eldoret, Kenya, 3Medicine, Moi University College of Health Sciences, School of Medicine, Eldoret, Kenya, 4University of Toronto, Dalla Lana School of Public Health, Toronto, ON, Canada, 5Behavioural Sciences, Moi University College of Health Sciences, School of Medicine, Eldoret, Kenya, 6Medicine, Indiana University School of Medicine, Indianapolis, IN, United States

1056 Cost Savings of Viral-Load Testing Before ART Second-Line Switch in a Resource-Limited Setting
Joanita Kigori, Christine Mugasha, Alex Mugurungi, Alex Coutinho, Yukari Manabe

1Infectious Disease Institute, Kampala, Uganda, 2Johns Hopkins University, Baltimore, MD, United States

1057 Peer Support and Engagement, HIV Care and Sexual Behaviors Among PLHIV Not on ART: A Randomized Trial
Larry W. Chang, Gertrude Nakigizzi, Vianna Billoux, David Szerwadda, Thomas Quinn, Robert Bollinger, Maria Wawer, Ronald Gray, Steven Reynolds

1Johns Hopkins School of Medicine, Baltimore, MD, United States, 2Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, 3Rakai Health Sciences Program, Entebbe, Uganda, 4Laboratory of Immunoregulation, Division of Intramural Research, National Institute for Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

1058 Community-Based ART Programs in Resource-Limited Settings
Stephen Okoboi, Ding Enni, Stephen Persaud, Jonathan Wangisi, Darius Kalit, Chen Yulin, Mauzen Nyonyito, Celestin Bakanda, Josephine Birungi, David Moore

1The AIDS Support Organisation, Kampala, Uganda, 2University of Alberta, Edmonton, AB, Canada, 3University of Maryland, Baltimore, MD, United States, 4University of California San Francisco, San Francisco, CA, United States, 5Makere University School of Public Health, Kampala, Uganda, 6Makere University, Kampala, Uganda, 7BC Centre for Excellence in HIV/AIDS, Vancouver, BC, Canada, 8University of British Columbia, Vancouver, BC, Canada
Session P-X3 Poster Session
Wednesday March 5, 2014, 2:30 PM–4:00 PM Exhibit Hall D
The Treatment Cascade and Loss To Follow-Up

1059 Gender Differences in Loss To Follow-up and Mortality in Older Adults On ART in Sub-Saharan Africa
Mansi Agarwal1, Matthew R. Lamb2, Veronica Mugisha2, Davies Kimanga2, Bonita Kliama3, Andrea A. Howard1, Elaine J. Abrams1, Wafa M. El-Sadrai1, Batya Eluf1

1060 Comparative Effectiveness of HIV Care and Treatment Programs in East Africa
Elvin Geng1, Thomas Odeny2, Rita Lyamuya3, Alice Nakivovgwa-Muwanga4, Mweheesa Swaana5, Paula Brailstein6, Andrew Karnbukutu7, Elizabeth Bukusai8, Geoffrey Somi9, Lameck Diero9, Jeffrey Marte9

1061 Loss To Follow-Up: Determining Outcomes for Adults Enrolled in HIV Services in Kenya

HIV Pathogenesis: Current Understanding and Future Research

Dana H. Gabuzda, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, United States

**Background:** HIV is transmitted via mucosal and intravenous routes, replicating initially in CD4+ T cells at mucosal sites and draining lymph nodes. Following systemic dissemination, a major reservoir of infection is established in gut-associated lymphoid tissues (GALT), which eventually leads to depletion of GALT CD4+ T cells, altered mucosal defenses, gut mucosal injury, and microbial translocation. Despite host immune responses and antiviral therapies that suppress viral replication, viral reservoirs persist in long-lived memory CD4+ T cells, including a stem-cell like population (Tscm). Additional reservoirs of viral persistence are established in macrophages in the brain and other macrophage-rich tissues. Chronic immune activation, a hallmark of HIV infection, is a strong predictor of disease progression, morbidity, and mortality that has also been linked to accelerated aging and age-related end-organ comorbidities involving the cardiovascular system, kidneys, liver, brain, endocrine system, and bone. Underlying causes of chronic immune activation include ongoing viral replication, persistently elevated interferon responses, and microbial translocation. Cofactors associated with the HIV epidemic, such as HCV and other co-infections, and substance abuse, can also increase innate immune activation and end-organ comorbidities. The mechanisms underlying immune dysregulation, chronic immune activation, and accelerated aging phenotypes in HIV infection are multifactorial and complex. Given this complexity, large multivariate datasets, systems biology, and computational approaches are needed to achieve systems-level understanding of HIV pathogenesis.

**Conclusions:** This talk will provide a systems-level overview of temporal events, pathogenic processes, and inter-relationships between immune dysregulation and end-organ dysfunction during the course of HIV infection. A better understanding of these processes at the cellular and host level, integration of knowledge from diverse types of high-density data, and temporal modeling of causal relationships and dependency networks is important for developing new therapies, and progress toward the ultimate goals of prevention and eradication.

HIV Cure Research

John W. Mellors, University of Pittsburgh, Pittsburgh, PA, United States

**Background:** Two highly-publicized cures of HIV infection, one in an adult who received complex therapies for leukemia including myeloablative chemotherapy, total body irradiation, anti-thymocyte globulin and allogeneic hematopoietic stem cell transplantation from CCR5 delta 32 homozygous donor, and one in an infant started on ART within 2 days of birth, have inspired worldwide efforts to cure HIV infection in more individuals. The recent relapse of HIV infection 3-8 months after stopping ART in two allogeneic bone marrow transplant recipients who had cleared HIV from blood is a sobering reminder of the difficulty in eliminating all replication-competent HIV from an infected host. In the context of data being presented at CROI 2014, I will review obstacles to curing HIV infection: i) long-lived cellular reservoirs (CD4+T-cells, microglia, other cell types); ii) latent-replication competent proviruses integrated across the human genome, iii) HIV diversity and immune escape variants, iv) clonal expansion of HIV-infected cells, v) persistent low-level viremia despite ART, and vi) highly-variable and incompletely effective host immune responses to HIV. I will then highlight curative approaches that are being explored: i) immediate ART after birth in HIV-infected infants; ii) ART in adults during acute/early HIV infection to prevent reservoir expansion and induce post-treatment immune control; iii) latency reversing agents to deplete HIV reservoirs; iv) reversal of exhaustion of HIV-specific through immune response by targeting inhibitory receptors (e.g. PD-1/PD-L1) on T-cells; iv) antibody-, cell-, and vaccine-based immunotherapies to enhance HIV immune responses; and vi) host modification to confer resistance to HIV replication.

**Conclusions:** Progress towards a cure of HIV infection will undoubtedly occur but the challenge of developing and delivering effective and scalable therapies to most HIV-infected persons is a formidable one.

HIV Vaccine Immunology: Recent Progress and Continuing Challenges

Richard A. Koup, Vaccine Research Center, National Institute of Allergy and Infectious Disease, National Institutes of Health, Bethesda, MD, United States

**Background:** A vaccine is clearly needed to stem the spread of HIV. A phase IIB HIV vaccine trial was recently stopped due to futility. The immune profile generated in this trial, as compared to a previous moderately protective trial, will help inform the next generation of HIV vaccines.

**Conclusions:** This presentation will highlight the advances that have been made in the last 12-18 months in defining potentially protective immune responses to HIV, and determining how to stimulate them through vaccination. Information will derive from five different approaches: 1) evaluation of results from past and present vaccine efficacy trials, 2) the generation of broadly neutralizing antibodies, and their effects in preventing and treating SHIV/HIV
infection in monkeys and humanized mice, 3) solving the crystal structure of a stabilized cleaved trimer of HIV envelope, 4) studies of how antibody and envelope co-evolve during HIV infection, and 5) determination of the unique characteristics of CD8 T cells generated in response to rhCMV vaccination that are capable of clearing SIV infection in monkeys. Throughout the presentation, information will be provided on where and when the latest information will be presented at CROI.

4  
**HIV Prevention Research: Progress and Challenges**  
Sharon L. Hillier, University of Pittsburgh School of Medicine, Magee-Womens Hospital, Pittsburgh, PA, United States

**Background:** HIV prevention trials have been conducted assessing a range of approaches to decrease the incidence of HIV infection, including vaccination, circumcision, vaginal and rectal microbicides, oral pre-exposure prophylaxis (PrEP) and treatment as prevention (TasP). Of these, male circumcision, one vaccine combination, 1% tenofovir gel used at the time of sex, oral emtricitabine/tenofovir or tenofovir, and effective treatment resulting in reduced viral load have all been shown to reduce HIV acquisition by 30 to 97%. Scale up of circumcision, which decreases the risk of HIV in men by >50%, has increased globally with the availability of new devices which permit the delivery of this procedure at low cost and high safety. Oral and topical antiretrovirals have emerged as potent tools for the prevention of HIV, and since the approval of emtricitabine/tenofovir by the FDA for prevention of HIV in 2012, a number of programs have been initiated to scale up the availability of PrEP and to explore the public health impact of this intervention. At the same time, there is an increased recognition that adherence to oral and topical PrEP is critical to the success of this approach. The FemPrEP and VOICE trials, which were conducted in populations of young women living in high seroconversion communities in Africa, each reported low levels of adherence to daily products. This factor likely accounted for the lack of reported efficacy in these studies, in contrast to the studies performed in men who have sex with men and HIV serodiscordant couples. Tenofovir gel is in a phase 3 clinical trial among women using a coital rather than daily approach (FACTS-001), and as a rectal microbicide in MSM (MTN-017). For new PrEP agents, strategies are focused on the sustained delivery of ARVs. One example is a vaginal ring which delivers low doses of the NNRTI dapivirine over a month of use, and randomized efficacy trials evaluating this approach are underway. Injectable ARVs are in phase 1 studies, with promising results emerging from animal models. The success of the HPTN 052 study which demonstrated that effective treatment of HIV-infected persons, resulting in virological suppression reduced HIV transmission by 97%, has led to the increased rollout of TasP as a key strategy in the HIV prevention toolbox. Of the HIV vaccines tested to date, only the RV144 HIV vaccine has been successful in reducing HIV incidence. Although the reduction in HIV was 31% with this vaccine and the results of this study likely only apply to those patients with subtype E virus, the study has energized the vaccine field and has led to the development of a vaccine protocol to assess the efficacy of this strategy against clade C HIV in S Africa in a study planned for 2015.

5  
**Pathogenesis and Control of HCV Infection**  
David L. Thomas, The Johns Hopkins University School of Medicine, Baltimore, MD, United States

**Background:** Hepatitis C virus (HCV)-related liver disease has emerged as one of the most important causes of morbidity and mortality in HIV-infected persons. Compared to persons with just one infection, HIV/HCV-coinfected persons have a higher incidence of all liver complications and even some extrahepatic conditions raising the possibility of multiple pathogenic interactions. HCV can be cured, even without interferon alfa, and HCV drug development is an exceedingly active basic and clinical research field. Medications are in trials that target nearly all major steps in replication. Highly-efficacious, single-tablet, 8-12 week, panenotypic therapies are already in development. Cure of infection reduces the incidence of liver disease complications and improves mortality. Cure rates among HIV/HCV coinfected persons are equivalent to those with just HCV.

Nonetheless, there remain enormous public health challenges. No more than 5% of the ~170 million persons has been prescribed treatment; no more than 10% worldwide and 50% in the US know their infection status. Moreover, most HCV treatment courses exceed $100,000 and yet their effectiveness can be completely abrogated by nonadherence or reinfection. Thus, models of disease control underscore the importance of coupling prevention with treatment.

**Conclusions:** 25 years after discovery of HCV, everything has changed for the 5% in care. But, enormous challenges remain and are even more urgent given the potential to cure.
Studying Multiple Interventions: Factorial Designs and Other Approaches

Richard J. Hayes, London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: In the simplest randomized controlled trial (RCT) design, individual patients are randomly allocated to two study arms (Intervention vs Control) to measure the effects of a specified health intervention on a defined outcome. In some cases, however, we wish to examine the effects of multiple interventions in the same trial. Examples of such studies include (1) treatments with multiple dosage regimens or alternative drugs; (2) studies designed to compare the effects of two or more different interventions, alone or in combination; (3) combination interventions where we wish to unpick the effects of different components. We will discuss some of the study designs that can be used to address such questions.

A simple design compares two or more intervention conditions with a single control arm. There are sometimes issues of multiple comparisons and, depending on the mode of delivery of the interventions, there may be a need for multiple placebos if a blinded design is required (e.g. double-dummy trials). When the separate or joint effects of interventions are of interest, the factorial design may be an attractive choice, for example the 2x2 factorial in which patients are randomized to four groups given either intervention A alone, intervention B alone, neither or both. Under certain assumptions, the factorial design permits the effect of more than one intervention to be measured in a single trial at a similar cost to a study designed to evaluate a single intervention. The limitations and strengths of this design will be reviewed, and implications for sample size outlined. Such trials may be randomised either at individual or cluster levels. In some cases, the two approaches may be combined, such that clusters are randomly allocated to the presence or absence of one intervention, while individuals or households within clusters are randomly allocated to presence or absence of another intervention (sometimes referred to as a split-plot design).

The above design choices will be illustrated with RCTs conducted to measure the effects of interventions against HIV and related infections, including the Zamstar, VOICE and PopART trials.

Conclusions: While it is often best to aim for simplicity of design, resources for rigorously-designed RCTs are limited and it is important to ensure that such resources are used efficiently. Sometimes, by careful choice of study design, it may be possible to evaluate several interventions in a single study at little additional cost. Alternative approaches to unpick the effects of combination interventions also need to be considered. In particular mathematical modelling may sometimes be used to supplement RCT evaluations.
9 So Many Trials, So Little Time: Meta-Analysis Do’s and Don’ts
Dean A. Follmann, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Background: Meta-analysis is a powerful method for quantitatively synthesizing multiple clinical trials of similar interventions. By combining multiple sources of information a sharper signal about the interventions can be calculated, both overall and in subgroups. While meta-analysis is a summarization of finished studies, pre-specification of the essential research question, study inclusion criteria, and analytic strategy increase rigor of the analysis.

Conclusions: Two main statistical calculations for summarizing studies are discussed. The fixed effects approach is best when the intervention effects are relatively homogeneous and provides conclusions about the studies at hand. The random effects approach is more suited for more heterogeneous intervention effects and generalizes beyond the studies at hand. Techniques to explore and address heterogeneity will be discussed as well as more subtle issues such as the bias introduced by non-publication of null studies, the temptation to dismiss “aberrant” studies, methods to accommodate differential quality of studies, and a perspective on the strength of evidence that can be achieved by meta-analysis. Examples involving vaccines and drugs will illustrate the use of meta-analysis to explore safety signals as well as variation in efficacy.

Session W3 Workshop
2:30 PM – 4:30 PM Ballroom A
Frontiers in Laboratory Science Workshop

10 Systems Immunology Approaches for Vaccine Profiling and Antibody Discovery
Sai Reddy, Swiss Federal Institute of Technology Zurich, Basel, Switzerland

Background: A major part of the advancement of the field of systems immunology has been the emergence of next-generation sequencing (NGS); specifically the ability to use NGS for large-scale analysis of antibody variable gene repertoires. Here, I will provide an overview of this exciting new research field, which has applications related to answering basic questions of antibody diversity, development, and evolution; as well as applications for immune-diagnostics and immunotherapeutics. I will primarily focus on our research group’s interests in applying NGS of antibody repertoires for the discovery and engineering of monoclonal antibody (mAb) therapeutics. This will include our recent development of a mAb discovery technology that requires no screening, which is based on NGS analysis of antibody repertoires obtained from immunized mouse plasma cells. This technology offers a powerful alternative to mAb discovery, which we are also utilizing for mAb discovery from immunized rabbits and chronically infected human patients.

Conclusions: We have also developed a number of experimental and computational methods to help advance NGS of antibody repertoires. These include a high-throughput bioinformatic pipeline for NGS analysis and annotation, operating at much faster times than currently used software (e.g., IMGT). Also, we have evaluated the robustness and reproducibility of antibody NGS sequencing methods using triplicate sample sequencing and mathematical ecology-based modeling. Finally, we have assessed experimental methods used to construct NGS antibody libraries, focusing on primer bias and the impact of adaptor addition by PCR or ligation. Our work on methods development should help researchers pursue their own goals related to antibody NGS and help advance the field of systems immunology.

11 3-D Structural Analysis of HIV Using Correlative CryoEM and Live Cell Imaging
Peijun Zhang, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States

Background: Following fusion of the viral and host membranes, the HIV-1 capsid core is released into the cytoplasm of the host cell. The viral capsid plays critical roles during the early stages of infection before nuclear entry by interacting with host cell machines. However, direct observation of structural details of infecting HIV-1 core has not been realized due to technological challenges in working with rare and dynamic HIV-1 particles in human cells. While time-lapse live-cell imaging has yielded a great deal of information about many aspects of the life cycle of HIV-1, the resolution afforded by live-cell microscopy is limited. On the other hand, cryo-electron tomography (cryoET) provides three-dimensional (3D) still pictures of near-native state cells and organelles at molecular resolution. By combining high-speed 3D live-cell fLM and high-resolution cryoET, the correlative light and electron microscopy (CLEM) method provides a powerful means to not only expand the imaging scale and resolution but also to complement the dynamic information available from optical microscopy with the molecular-level, 3D ultrastructure detail provided by cryoET.

Conclusions: I demonstrate the capability of the correlative microscopy method by directly visualizing dynamic, small HIV-1 particles interacting with host HeLa cells. Furthermore, using high resolution cryoEM and helical reconstruction, the structure of HIV-1 capsid assembly is determined to 8Å resolution, clearly delineating all the α-helical motifs within the capsid structure. The structure allowed unambiguous modeling and refinement by large scale molecular dynamics simulations, resulting in an all-atom model of the HIV-1 capsid comprising 4 million atoms. The model revealed new hydrophobic interactions at the seam of capsid assembly, and provides a platform for further studies of capsid function and for targeted pharmacological intervention.
12  **Virus-Host Interactions Revealed Through Proteomics/Phosphoproteomics**  
**Beatrice Ueberheide**, New York University Langone Medical Center, New York, NY, United States

**Background:** Mass Spectrometry has become an indispensable technique for studying proteins in biological systems. Thousands of proteins can be identified and quantified with state-of-the-art instruments in a single experiment. Global changes in the proteome and certain post-translational modifications can now be routinely characterized due to dramatic improvements in speed and sensitivity of mass spectrometric instruments and data analysis software. However, there are still areas of proteomics where analysis can be not as straightforward or need extra care in sample preparation. Examples are the characterization of disease specific circulating antibodies and the detection of virus-host protein interactions.

**Conclusions:** Protein-Protein interactions are critical for all cellular processes. Understanding with which host proteins the virus interacts is crucial for understanding the mechanism of infection. Current strategies of affinity purifications of tagged viral proteins, chemical cross-linking of host-virus proteins as well as changes in post translational modifications (i.e. phosphorylation) upon infection will be presented. Common problems of affinity purifications and characterizing infection dependent post translational modifications will be discussed with special emphasis on sample preparation strategies. Establishing antibody repertoire of infected individuals by high throughput DNA sequencing has been rapidly advancing, yet the antibody composition in the blood of infected individuals remains largely unknown. Here, mass spectrometry is emerging as an enabling technology in combination with a match personal antibody database. Characterizing and quantifying the circulating antibodies in the blood of infected individuals is however not a trivial task. The majority of the antibody is structurally identical and it is therefore difficult to unambiguously identify which antibody is present in the sera of individuals. The majority of antibody derived peptides will be identical and shared between many different antibodies. Here, current strategies for identifying antibody specific peptides are described.

13  **CRISPRs and Other Genome Editing Systems**  
**Paul F. Bates**, University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA, United States

**Background:** Precise genome-editing techniques have been developed recently that allow researchers to delete, insert, and modify DNA in human cells and other animal cells grown in culture. These technologies include zinc-finger nucleases (ZFNs), transcription activator-like effector nucleases (TALENs), and the clustered regulatory interspaced short palindromic repeat (CRISPR) system. This review will focus mainly upon the most recently described Cas9/CRISPR system as a tool that can be readily employed in individual laboratories.

**Conclusions:** The emerging technology of genome editing is based on the use of engineered nucleases to produce specific DNA cleavages at defined target sites. Repair of these cleavages by host enzymatic machinery, either non-homologous end-joining (NHEJ) or homologous recombination (HR) repair, results in either loss/insertion of some sequence or substitutions in the broken region. This review will describe site-specific nuclease technologies and discuss their employment for genetic analysis and manipulation for both research and potential therapeutic application.

ZFNs and TALENs rely upon sequence-specific DNA-binding domains fused to a nonspecific DNA cleavage module. Although the modular nature of the ZFN and TALEN DNA recognition domains permits design and production of nucleases targeting of virtually any sequence, they can be difficult to produce by individual labs prompting many to use commercial sources. Unlike ZFN or TALEN, the CRISPR/Cas9-mediated genome editing system utilizes a small guide RNA to recognize and direct activity of the endonuclease. This system can be effectively employed by individual labs and the tools for utilizing CRISPRs are readily available. In addition to gene editing in cultured cells where numerous groups have used CRISPRs to create genetic knockouts and gene replacements, they have also been used to create gene modifications in whole animals such as mice, rats, and zebrafish. Very recent advances have demonstrated application of the CRISPR and TALEN mutagenesis approaches in nonhuman primates where one can model disease and develop therapeutic strategies with obvious direct application to HIV infection. Finally, important hurdles that remain before CRISPR-mediated gene correction could be used for therapeutic applications will be discussed.

Session W4 Workshop  
2:30 PM – 4:30 PM  
**Room 304**

**Workshop for Clinicians Who Are New To Hepatitis C Management: A Case-Based Interactive Session**

14  **Liver Management**  
**Kenneth E. Sherman**, University of Cincinnati College of Medicine, Cincinnati, OH, United States

**Background:** New agents for HCV treatment have dramatically improved both ease and success of treatment intervention. It is imperative that healthcare providers managing HCV understand key concepts in the staging of liver disease, and critical management considerations. Staging of liver disease to determine if advanced fibrosis or cirrhosis is present remains important. Cirrhosis is associated with poorer treatment outcomes and increased risk of hepatic decompensation and liver cancer. A variety of modalities are now available for staging of liver disease including non-invasive measures such as transient elastography and biomarker algorithms. Liver biopsy may still play a role in a limited proportion of patients. Determination of advanced fibrosis/cirrhosis mandates enrollment in hepatocellular carcinoma (HCC) surveillance and evaluation of esophageal varices. Careful assessment is needed in the setting of cirrhosis to determine liver transplant candidacy prior to treatment intervention.

**Conclusions:** HCV healthcare providers should be familiar with the process of fibrosis staging, and appropriately identify patients who would benefit from surveillance for HCC and esophageal varices. Hepatic decompensation recognition is critical and should lead to rapid consultation with a liver transplant specialist.
Interactive Case Presentations

David L. Wyles, University of California San Diego, San Diego, CA, United States
Susanna Naggie, Duke Clinical Research Institute, Durham, NC, United States

Background: The recent approval of more potent and better-tolerated therapies for HCV infection, including in those with HIV-1 co-infection, heralds the beginning of a new era in HCV therapeutics. Interferon-free therapy is the new standard of care for patients with genotype 2 or 3 HCV infection; while highly efficacious IFN-containing triple therapies with a shortened duration are an option for those with genotype 1 HCV infection.

As HCV therapy becomes less complex and as expanded screening efforts are implemented, more providers will be needed to accommodate the increased number of patients wanting or requiring HCV therapy. While the recent advances have brought significant improvements in HCV therapy for genotype 1 infection, more advances are expected over the next 1-2 years, in particular the arrival of interferon-free therapy. Thus many clinicians are faced with the complex issue of deciding whether to initiate therapy now or defer with the promise of better therapies in the near future. An understanding of the clinical trial data summarizing new and future treatment regimens as well a review of the complexity of management in the HIV-1 infected patient population including but not limited to drug–drug interactions will be discussed.

Conclusions: This interactive case-based session is geared toward clinicians who are new to HCV care and will cover key aspects related to: 1) decision making on HCV treatment initiation versus deferral, 2) use of interferon-free therapy for HCV genotype 2 and 3 infection, 3) recognizing advanced and early decompensated liver disease, and 4) managing HCV therapy and drug interaction in a co-infected patient with genotype 1 infection.

Opening Session
5:00 PM – 7:00 PM Auditorium

Session NL1 Lecture
Bernard Fields Lecture

Making and Breaking Barriers To Cross-Species HIV-1 Transmission
Paul D. Bieniasz, Aaron Diamond AIDS Research Center, The Rockefeller University, New York, NY, United States

Background: The investigation of impeded viral replication in cells of particular types or species has uncovered great complexity in the interaction between retroviruses and their hosts. These studies have revealed that many mammals, including humans, are equipped with a diverse set of gene products that inhibit the replication of human and simian immunodeficiency viruses. Antiretroviral genes exhibit unusually high diversity in primates, presumably because selection pressures exerted by ancient viral infections have caused them to evolve at an unusually rapid pace. The adaptation of modern retroviruses to specific variants of antiviral proteins has resulted in viral specialization to particular host species and the creation of formidable barriers to replication in other species. These phenomena likely protect humans from infection by many modern retroviruses, but have also impaired the development of primate models of HIV-1 infection.

Conclusions: This presentation will (1) review some of the salient features of antiretroviral proteins, (2) discuss studies of Tetherin, an example of an antiviral protein that inhibits the release of virus particles from infected cells and (3) describe our attempts to break antiviral protein-imposed barriers to cross-species transmission of HIV-1 in order to generate better animal models of human AIDS.

Session NL2 Lecture
N’Galy-Mann Lecture

Application of Scientific Knowledge and Evidence To Limit the Progression of HIV/AIDS and Fight Other Endemic Diseases in West Africa
Souleymane Mboup, Centre Hospitalier Universitaire Aristide le Dantec, Dakar, Senegal

Background: Senegal has experienced long success in HIV control, maintaining an HIV prevalence below 1% within the adult general population aged 15 to 49 years.

Senegal’s success has been attributed to a number of factors:
• Political leadership
• National Program And Related National Plans
• Control of STDs
• Safe blood supply
• Strong strategic information system
• Social and religious support
• Early availability of ARV therapy
• Research to inform the national effort

Research was able to show that the initial infections in-country were from the less virulent HIV-2 form. The first HIV-1 case was not observed until 1986.

Conclusions: Research was instrumental: It is now 29 years that HIV-2 has been described in Senegal. Since that time, several international research collaborations have sought to understand the pathogenicity of this closely related HIV virus and the impact of its interaction with the prototype HIV-1 infection in vivo. Co-existing in West Africa with HIV-1, HIV-2, by contrast, generally demonstrates an attenuated phenotype for transmission and disease.
Our group described the details of disease progression and pathogenesis of HIV-1 and HIV-2 and then translated that knowledge to begin a long-term investigation of disease transmission.

Our team made great efforts to lend our expertise to various other countries where the epidemic was much more severe. With our regional training we have also established a large number of AIDS experts who have moved back to various countries on the African continent to assist these countries in establishing their own programs for teaching and research. Now we lead a research group of about 120 junior colleagues mainly conducting AIDS research and this is widely seen by outsiders as the largest and most productive AIDS research program in Africa that is run and staffed by Africans. Key to this is the insistence on staying at our base in Dakar despite many very attractive offers to be based overseas. Over the past 15 years, we have expanded our scientific interests into other areas of infectious diseases important to Senegal and West Africa, including malaria and tuberculosis, where we have initiated research programs patterned on the successful HIV-AIDS programs. Importantly, the Senegal collaboration was the model that guided the collaborations in many countries, such as Tanzania, Botswana and Nigeria. This breadth of accomplishments has mainly the objective to demonstrate one of the best role models for young African scientists seeking to build a major research career in biomedical sciences.

TUESDAY MARCH 4, 2014

Session PL1 Plenary
8:30 AM – 9:00 AM Auditorium

19 HPV Vaccines: Progress To Date and Future Worldwide Directions
Douglas R. Lowy, National Cancer Institute, Bethesda, MD, United States

Background: Human Papillomaviruses (HPVs) cause several epithelial cancers as well as a range of benign lesions. Cervical cancer is the most serious cancer worldwide attributable to HPV infection, as it accounts for almost 10% of all cancer in women and is the most common female cancer in many developing countries. In the US, the incidence of HPV-positive “non-cervical” cancers, which include anal, vulvar vaginal, penile, and oropharyngeal cancer, is similar to that of cervical cancer. More than 10 HPV types have been shown to be oncogenic, although HPV16 and HPV18 (HPV16/18) together account for about 70% of the cervical cancers and an even higher proportion of the non-cervical cancers. There are two FDA-approved sub-unit HPV vaccines, both of which are based on the ability of the major L1 capsid protein of HPVs to self-assemble into virus-like particles (VLPs), which are highly immunogenic. The main protective activity of the vaccines is their induction of neutralizing antibodies, which are HPV type-restricted. A full course of vaccination involves 3 doses over a 6 month period. The vaccines are highly effective against the HPV types they target (vaccine types), but have more limited activity against non-vaccine types. Two important goals of second generation HPV vaccines are to safely reduce the number of doses required to induce long-term protection, and to increase the number of HPV types efficiently protected by HPV vaccination.

Conclusions: The presentation will focus on research efforts to accomplish these goals.

Session PL2 Plenary
9:00 AM – 9:30 AM Auditorium

20 HIV in People Who Use Drugs
Adeeba Kamarulzaman, University of Malaya, Kuala Lumpur, Malaysia

Background: Despite ample evidence of the effectiveness of several interventions to prevent HIV among people who use drugs, the global goal of reducing transmission by 50% by 2015 is not likely going to be achieved. Coverage of these key interventions such as needle and syringe programs and medically assisted therapy remain low particularly in low and middle income countries. In addition to HIV, people who use drugs are also at higher risk for a number of other medical complications including tuberculosis and viral hepatitis. In most countries however, access to treatment for these infections remains poor and treatment services are often segregated.

Implementing treatment as prevention for people who use drugs poses many challenges including delays in entering into care, provider reluctance to commence antiretroviral therapy and issues with adherence in those who are actively using drugs. Additionally, incarceration of people who use drugs further reduces access to HIV and other treatment as well as fuel the twin epidemic of HIV and tuberculosis in this population.

Conclusions: Despite evidence of effectiveness and cost-effectiveness of key interventions to prevent and treat HIV infection in people who use drugs, the current global response to the HIV epidemic in this population remains poor. Although policy shifts with increasing coverage of key interventions are beginning to take place in several countries with high disease burden, criminalisation of drug use, incarceration and stigma and discrimination continue to present as main barriers to an effective combination prevention and treatment response. A concerted global effort that addresses individual as well as structural and systematic barriers is needed if we are to expect a decline in HIV transmission among people who use drugs and improve the health and well-being of these individuals.
21 Longitudinal Phenotypic Profiling of Early HCV-Specific CD4 T Cells in HIV- and HIV+ Individuals

1Gastrointestinal Unit, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, 2Infectious Disease Division, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, 3Laboratorio de Hepatites Virais, Instituto Oswaldo Cruz, Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil, 4Benaroya Research Institute at Virginia Mason, Seattle, WA, United States

Background: HCV infection generally progresses to chronic infection, but a minority of individuals can spontaneously clear the infection. CD4 T cells are critical for the spontaneous control of HCV but the mechanisms of protection and immune failure remain to be elucidated, especially in HIV+ individuals who generally have higher rate of chronic viremia.

Methodology: We longitudinally analyzed the immunophenotype of early HCV-specific CD4 T cell responses in 45 genotype-1 HCV-infected individuals with well-defined clinical outcomes, including 6 patients with a pre-existing HIV-1 infection. HCV-specific CD4 T cells were studied directly ex vivo using a panel of HCV-MHC class II tetramers, and analyzed for their expressions of various immune makers in multicolor flow cytometry. All statistical analyses were performed with the Spearman correlation test.

Results: HCV-specific CD4 T cells were initially detectable directly ex vivo by MHC class II tetramers in 15/15 (100%) resolvers and 16/24 (67%) progressors with mono-HCV infection, as well as in 6/6 (100%) HIV+ individuals, including one who spontaneously cleared HCV. HCV-specific CD4 T cells disappeared from most progressors within 13-41 weeks after onset of infection, while these cells persisted in patients with resolving infection. Early HCV-specific CD4 T cells were mostly comprised of activated effector memory cells expressing high levels of PD-1, CTLA-4, and CD95, and low levels of CD127, irrespective of infection outcomes and HIV status. Interestingly, CD38, PD-1, CTLA-4, and CD95 were quickly downregulated with resolution of infection. Furthermore, decreased expressions of CD38 (p<0.0001), PD-1 (p<0.0001), and CTLA-4 (p<0.0001) were associated with increased expression of CD127 on HCV-specific CD4 T cells. In contrast, in persisting infection HCV-specific CD4 T cells continued to express high levels of CD38, PD-1, CTLA-4, and CD95, and failed to upregulate CD127 before disappearing from blood. Finally, HCV-specific CD4 T cells in resolving infection predominantly expressed CCR4 while expressing intermediate levels of CXCR3 and low levels of CCR6, CXCR5, and Foxp3. In contrast, there was a trend towards more Foxp3, CXCR5, and CXCR3 and fewer CCR4 expressing HCV-specific CD4 T cells in persisting infection.

Conclusions: Both HIV+ and HIV- patients generate HCV-specific CD4 T cell responses with a uniform phenotype in the early phase of acute infection, indicating that priming of response does not explain infection outcomes. However, with persistent viremia, HCV-specific CD4 T cells quickly display the phenotypes, resembling those of exhausted and dysfunctional T cells, irrespective of HIV-1 status. These changes may contribute to viral persistence and the rapid disappearance of HCV-specific CD4 T cells.

22 Rapid Peripheral In Vivo Cellular Changes During Interferon-Free Treatment of Hepatitis C
Eric G. Meissner1, Brian Santich1, Yu-Jin Lee1, Olga Prokunina1, Anuoluwapo Osinusi1, 2, Anita Kohli1, 2, Henry Masur3, Susan Moir1, Shyamasundaran Kottilli1

1Laboratory of Immunoregulation, NIAID/NIH, Bethesda, MD, United States, 2SAIC-Frederick, Inc, Frederick, MD, United States, 3CCMD/NIH, Bethesda, MD, United States

Background: Treatment of chronic hepatitis C virus (HCV) infection is evolving from interferon (IFN)-based to IFN-free directly acting antiviral (DAA) regimens. IFN-based therapy causes treatment-induced cytopenias, while cellular changes on DAA therapy are not well described. Because cellular changes on DAA therapy may reflect the host response to viral decline rather than a treatment side effect, we explored changes in peripheral cell populations during two DAA trials conducted at the NIAID.

Methodology: We evaluated chronic HCV genotype-1 treatment-naïve patients treated with sofosbuvir/ribavirin for 24 weeks (SPARE trial, n=55) or sofosbuvir/ledipasvir for 12 weeks (SYNERGY trial Arm A, n=20). Peripheral cell populations were quantitated by flow cytometry and results were analyzed using a mixed model (SPARE) or non-parametric ANOVA (SYNERGY). Chemokine
Faldaprevir Plus Pegylated Interferon Alfa-2a/Ribavirin in HIV/HCV Coinfection: STARTVerso4

Douglas Dieterich1, Cristina Tural2, Mark Nelson3, Keikawus Arastéh4, Vicente Soriano5, Josep Guardiola6, Sanjay Bhagani7, Jürgen K. Rockstroh8, Jerry O. Stern9, Anne-Marie Quinson10

1Mount Sinai Medical Center, New York, NY, United States, 2Hospital Universitat Germans Trias i Pujol, Barcelona, Spain, 3Chelsea and Westminster Hospital, London, United Kingdom, 4EPIMED/Vivantes Auguste-Viktoria-Klinikum, Berlin, Germany, 5Hospital Carlos III, Madrid, Spain, 6Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, 7The Royal Free Hospital, London, United Kingdom, 8Department of Medicine I, University of Bonn, Bonn, Germany, 9Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT, United States

Background: Faldaprevir (FDV) is a potent, once-daily HCV NS3/4A protease inhibitor being developed for the treatment of chronic HCV infection in mono-infected patients and patients co-infected with HIV. The objective of STARTVerso4 is to assess efficacy and safety of FDV + pegylated interferon alfa-2a/ribavirin (PR), and evaluate response-guided treatment duration in HIV patients co-infected with HCV genotype (GT) 1.

Methodology: This phase III, open-label, sponsor-blinded study included HCV/HIV co-infected patients who were HCV treatment naïve (TN) or relapsed after prior interferon-based HCV therapy. The study had 2 arms: arm A, 120 mg FDV for 24 weeks (W); arm B, FDV 240 mg for 12W or 24W (duration determined by on-treatment response). Both arms investigated response-guided duration of the PR backbone. At W24, all patients who achieved early treatment success (ETS, HCV RNA <25 IU/mL at W4 and undetected at W8) were re-randomized to stop all treatment at W24 or continue PR up to W48. Patients without ETS received PR through W48. Patients on protease inhibitor-based antiretroviral regimens were assigned to arm A and patients on efavirenz-based regimen were assigned to arm B. All other patients were randomized. The primary endpoint was sustained virologic response 12W after the end of treatment (SVR12).

Results: A total of 308 patients were treated (mean age 47 years, 81% male, 83% White, 14% Black/African American, 29% ≥F3 liver fibrosis, 79% GT1a, 66% IL28B non-CC rs12979860, 78% TN). HAART was used by 96% of patients. SVR4 data were available for all patients. Efficacy endpoints are summarized in the table.

|Table footnotes| n/N (%) | Arm A: FDV 120 mg | Arm B: FDV 240 mg | All patients (N=308) |
|--------------|-----------------|-----------------|---------------------|
|ETS           | 95/123 (77)     | 70/84 (83)      | 73/86 (85)          | 150/185 (81) | 245/308 (80) |
|SVR4          | 89/123 (72)     | 66/84 (79)      | 72/86 (84)          | 140/185 (76) | 229/308 (74) |
|ETS and SVR4  | 85/95 (90)      | 62/70 (89)      | 67/73 (92)          | 131/150 (87) | 216/245 (88) |
|SVR4 with PR 24 wks | 40/43 (93) | 23/26 (89) | 35/38 (92) | 58/64 (91) | 98/107 (92) |
|SVR4 with PR 48 wks | 41/42 (98) | 40/43 (93) | 27/29 (93) | 67/72 (93) | 108/114 (95) |

Conclusions: In this interim analysis, the safety profile and SVR4 rate (74%) for FDV + PR in HIV/HCV GT-1 co-infected patients were comparable with those obtained in HCV mono-infected patients, suggesting that FDV + PR might represent an important option for the treatment of HCV GT-1 infection in patients co-infected with HIV with or without HAART.
Simeprevir (TMC435) Plus PegIFN/Ribavirin in HCV Genotype-1/HIV-1 Coinfection (Study C212)

Douglas Dieterich, Jürgen K. Rockstroh, Chloé Orkin, Marina B. Klein, Jacques Reyes, Lotte Tambuyzer, Monika Peeters, Alan Jenkins, Wolfgang Jessner

Icahn School of Medicine at Mount Sinai, New York, NY, United States, Medizinische Universitätsklinik I, Bonn, Germany, Royal London Hospital, London, United Kingdom, Hospital General de Elche and Universidad Miguel Hernández, Alicante, Spain, McGill University Health Centre, Montreal, QC, Canada, Gui De Chauliac University Hospital, Montpellier, France, Janssen Infectious Diseases BVBA, Beerse, Belgium, Janssen Research & Development, Raritan, NJ, United States

Background: Simeprevir (TMC435, SMV) is a potent, oral, once-daily (QD), investigational HCV NS3/4A protease inhibitor with activity against HCV genotypes 1, 2, 4, 5, and 6. This ongoing Phase III, open-label trial is investigating efficacy and safety of SMV plus peginterferon/ribavirin (PR) in treatment-naïve or -experienced patients (pts) co-infected with HCV genotype 1 and HIV-1.

Methodology: Pts received SMV 150 mg QD (12 wks) + PR (24/48 wks). Non-cirrhotic treatment-naïve pts or prior relapers received response-guided treatment with PR for 24 or 48 wks. Prior partial or null responders and cirrhotic pts received PR for 48 wks. Primary endpoint for HCV: sustained virologic response (SVR) rate 12 wks after end of treatment. SVR12 was determined in key subgroups (HCV genotype 1a/1b; METAVIR score; concomitant HAART). Secondary endpoints included HIV virologic response, safety. A pre-defined single-sided z-test was used to compare SVR12 rates for treatment-naïve and prior null responders with historic controls.

Results: 106 pts were treated (84.9% male; 82.1% white; 14.2% black/African American; median age 48 years; median baseline absolute CD4+ count 628.5/mm³; median baseline log10 HIV RNA 4.18 copies/mL [pts not on HAART]). Most (82.1%) were infected with HCV genotype 1a, 12.3% had cirrhosis, and 87.7% were receiving HAART (NRTI, 98.9%; INI, 87.1%; NNRTI, 15.1%). SVR12 rate was 73.6% overall (treatment-naïve 79.3%; prior relapers 86.7%; prior partial responders 70.0%; prior null responders 57.1%) and was high in subgroups, albeit pt numbers were low (Table 1). SVR12 was achieved by 7/9 (77.8%) pts with METAVIR F4. HIV virologic failure (confirmed HIV RNA ≥ 200 copies/mL) rate among pts on HAART was 2.2% (2/93), which occurred 36 and 48 wks after completion of SMV, respectively. Incidence/profile of adverse events (AEs) was comparable to that in HCV mono-infected pts. During SMV and PR treatment, 35 (33%) pts had a Grade 3/4 AE, 6 (5.7%) had serious AEs, and 4 (3.8%) discontinued SMV due to an AE (mostly together with PR); in pts on HAART, 33/93 (35.5%) had Grade 3/4 AEs, 6 (6.5%) had serious AEs, and 4 (4.3%) discontinued SMV due to an AE.

Conclusions: SMV 150 mg QD with PR led to high SVR rates in pts co-infected with HCV genotype 1 and HIV-1, regardless of prior HCV treatment response, HCV genotype 1a/1b, baseline METAVIR score, and concomitant HAART. SMV with PR was well tolerated when co-administered with HAART and did not impact HIV treatment outcome.

All-Oral Combination of Daclatasvir, Asunaprevir, and BMS-791325 for HCV Genotype 1 Infection

Gregory T. Everson¹, Paul J. Thuluvath², Eric Lawitz³, Tarek Hassanein⁴, Maribel Rodriguez-Torres⁵, Trevor Hawkins⁶, Vinod Rustgi⁷, Federico Henestrosa⁸, James Levin⁹, Karen Sims¹⁰

¹University of Colorado Denver, Aurora, CO, United States, ²Mercy Medical Center, Baltimore, MD, United States, ³The Texas Liver Institute, University of Texas Health Science Center, San Antonio, TX, United States, ⁴Southern California Liver Centers, Corona, CA, United States, ⁵Fundación de Investigación, San Juan, Puerto Rico, ⁶Southwest CARE Center, Santa Fe, NM, United States, ⁷Metropolitan Research, Arlington, VA, United States, ⁸Orlando Immunology Center, Orlando, FL, United States, ⁹Dean Foundation for Health, Research and Education, Inc, Madison, WI, United States, ¹⁰Bristol-Myers Squibb, Hopewell, NJ, United States

Background: The all-oral triple combination of daclatasvir (DCV; NSSA inhibitor), asunaprevir (ASV; NS3 inhibitor), and BMS-791325 (‘325; non-nucleoside NSSB inhibitor) achieved sustained virologic response (SVR) rates >90% in pilot cohorts of non-cirrhotic patients with chronic HCV genotype (GT) 1 infection. The present study expansion (AI443-014) evaluates this regimen in larger cohorts that include cirrhotic patients, with all components dosed BID to support coformulation development.

Methodology: 166 treatment-naïve, HCV GT 1-infected patients were randomly assigned (1:1) to receive a twice-daily regimen of DCV 30mg, ASV 200mg, and ‘325 75mg (n=80) or 150mg (n=86) for 12 weeks. Randomization was stratified by GT1 subtype and presence of cirrhosis. The primary endpoint is HCV RNA <LLOQ (25 IU/mL) at 12 weeks posttreatment (SVR4). SVR results are reported here; SVR4 will be presented.

Results: Baseline characteristics were comparable across treatment groups; overall, patients were 56% male, 83% white, 82% GT1a, 67% IL28B non-CC genotype, and 9% cirrhotic. Among all patients with available data at posttreatment Week 4, SVR was achieved by 72/78 (92.3%) and 77/84 (91.7%) patients in the ‘325 75mg and 150mg groups, respectively, including 13/15 (86.7%) cirrhotic patients (Table. Efficacy Outcomes). Overall, 5/166 patients experienced on-treatment virologic breakthrough and, to date, 6/166 relapsed posttreatment; all of these patients had GT1a infection. In each group, 1 patient discontinued due to an AE (unrelated esophageal neoplasm, throat tightness); there were no deaths and no treatment-related serious AEs or grade 3/4 AEs. The most frequent AEs in both groups were headache, diarrhea, fatigue, and nausea. The only grade 3/4 liver-related lab abnormalities were single events of elevated AST (grade 3) and total bilirubin (grade 3) in different patients.

Conclusions: Twelve weeks of all-oral treatment with DCV + ASV + BMS-791325 achieved an overall SVR4 rate of 92% in a predominantly GT 1a population, with comparable response rates in cirrhotic and non-cirrhotic patients and low rates of virologic failure. The regimen was generally well tolerated, with similar safety profiles for both ‘325 dose groups. Further evaluation of this triple regimen is ongoing in broader patient populations, including GT4 infection and prior GT1 null responders.

Sofosbuvir Plus Ribavirin for HCV Genotype 1-3 Infection in HIV Coinfected Patients (PHOTON-1)

Susanna Naggie¹, Mark Sukowski², Jacob Lalezari³, W. Jeffrey Fessel³, Karam Mounzer⁴, Margaret Shuhart⁵, David Asmuth⁶, Douglas Dieterich⁷, Maribel Rodriguez-Torres⁸, and The Gilead PHOTON-1 Study Team

¹Duke Clinical Research Institute, Durham, NC, United States, ²The Johns Hopkins Institute, Baltimore, MD, United States, ³Quest Clinical Research, San Francisco, CA, United States, ⁴Kaiser Permanente, San Francisco, CA, United States, ⁵Philadelphia FIGHT, Philadelphia, PA, United States, ⁶Harborview Medical Center, Seattle, WA, United States, ⁷San Francisco General Hospital, San Francisco, CA, United States, ⁸University of California Davis Medical Center, Sacramento, CA, United States, ⁹Mount Sinai School of Medicine, New York, NY, United States, ¹⁰Fundación De Investigación, San Juan, PR, United States

Background: Interferon-free treatments for HCV that can be safely co-administered with antiretroviral therapy (ART) are needed for HIV/HCV co-infected patients. We evaluated the safety and efficacy of sofosbuvir (SOF), a pan-genotypic HCV NS5B inhibitor, with ribavirin (RBV) in HCV genotype (GT) 1-3 patients co-infected with HIV.

Methodology: HCV patients with stable HIV disease received SOF 400 mg OD and RBV 1000-1200 mg/day; treatment-naïve (TN) GT 1 and treatment experienced (TE) GT 2/3 patients received 24 weeks and treatment naïve GT 2/3 patients received 12 weeks of treatment. Multiple ART regimens were permitted, as were patients with compensated cirrhosis. The primary efficacy endpoint was sustained virologic response 12 weeks after treatment (SVR12); safety assessments included HIV RNA and CD4 cell count.

Results: Baseline characteristics and virologic responses are shown in the table. Among treatment naïve GT 2 and 3 patients, SVR12 was achieved in 88% (23/26) and 67% (28/42), respectively. Among the 13 virologic failures, only one had on-treatment virologic breakthrough due to study drug non-adherence, all other failures were due to relapse. No S282T resistance mutations have been detected from virologic failures to date. Complete SVR24 results for all groups, including treatment-experienced GT 2 and GT 3 patients, will be presented. In all groups, treatment discontinuations due to adverse
events (AEs) have been uncommon (3%) and grade 3/4 AEs were reported in 25 (11%) patients. Two patients had HIV breakthrough: one in the setting of ART non-adherence, and one regained HIV control without ART change.

Conclusions: Treatment-naïve HCV GT 2 and 3 patients coinfected with HIV achieved high rates of SVR12 with an interferon-free, all-oral regimen of SOF+RBV. These data suggest that SOF+RBV treatment is well-tolerated and safely co-administered with multiple ART regimens and may be equally safe and efficacious in patients with and without HIV coinfection.

27LB Combination Oral, Hepatitis C Antiviral Therapy for 6 or 12 Weeks: Final Results of the SYNERGY Trial

Anita Kohli1, 2, Zayani Sims1, Amy Nelson3, Anu Osinusi1, 4, Geb Tefari5, Phil Pang6, William Symonds6, John McHutchison6, Henry Masur1, Shyam Kottilil6
1Critical Care Medicine Department, National Institutes of Health, Bethesda, MD, United States, 2Clinical Research Directorate/Clinical Monitoring Research Program, Leidos Biomedical Research, Inc. (formerly SAIC-Frederick, Inc.), Frederick National Laboratory for Cancer Research, Frederick, MD, United States, 3Laboratory of Immunoregulation, National Institutes of Health, Bethesda, MD, United States, 4University of Maryland, Baltimore, MD, United States, 5Unity Health Care, Washington, DC, United States, 6Gilead Sciences, Foster City, CA, United States

Background: Combining multiple directly acting antiviral agents (DAA) is a plausible approach to reduce the duration of therapy required to cure HCV infection. In this study treatment regimens targeting multiple stages of HCV replication were evaluated for safety and efficacy in a historically difficult to treat population.

Methodology: Sixty HCV mono-infected, treatment naïve, GT-1 patients were consecutively enrolled into 3 arms of a phase 2 prospective cohort study and received: Arm A - sofosbuvir with ledipasvir (400mg/90mg respectively once daily in a fixed dose combination (FDC)) for 12 weeks, Arm B - FDC + GS-9669 (500mg/day), a non nucleoside NS5B inhibitor for 6 weeks, or Arm C - FDC + GS-9451 (80mg/day), an HCV protease inhibitor for 6 weeks. Serial measurements of safety parameters, virologic (HCV RNA by Roche Taqman PCR and Abbott assay; deep sequencing of baseline mutations) and host correlates (intrahepatic and peripheral by flow cytometry) were performed.

Results: Patients enrolled were predominantly African American (88%), male (72%), infected with GT-1a (70%), had a high HCV VL (>800k) (70%) with an IL28B non-CC haplotype (82%). Baseline demographics were similar between patients across arms and 35%, 25% and 25% of subjects on Arm A, B and C, respectively, had stage ≥3 liver fibrosis. No patients with cirrhosis were included in Arm B or C. The end of treatment response (HCV RNA <LLOQ) was 100%, 75% and 95% of subjects in Arms A, B and C respectively using a more sensitive HCV assay with lower limit of quantification of 12 IU/mL (Fig 1). Using an HCV RNA assay with a lower limit of quantification of <43 IU/mL 100% of patients on all arms were suppressed at EOT. 100%, 90% and 95% of patients in Arm A, B and C respectively achieved SVR12. One patient in Arm B experienced viral relapse. One patient on Arms A and B each missed their SVR12 visit. The combination was well tolerated with no grade 4 adverse events or drug discontinuations.
Conclusions: In this inner city patient population addition of a third antiviral agent allowed successful eradication of HCV in 6 weeks in a difficult to treat patient population. This study presents a new paradigm of combination therapy to reduce HCV treatment duration, which may be vital in the treatment and eradication of HCV globally.

28LB Daclatasvir in Combination With Simeprevir ± Ribavirin for Hepatitis C Virus Genotype 1 Infection

Stefan Zeuzem1, Christophe Hezode2, Jean-Pierre P. Bronowicki3, Veronique Loustaud-Ratti4, Francisco Gea5, Maria Buti6, Maria Beumont-Mauvel7, Navdeep Boparai8, Gaston Picchio9, Stephanie Noviello9, on behalf of the LEAGUE-1 Study Team

1JW Goethe University Hospital, Frankfurt a.m., Germany, 2Hôpital Henri Mondor, Paris, France, 3Centre Hospital Universitaire de Nancy, Vandoeuvre Les Nancy, France, 4Université Limoges, Limoges, France, 5University Hospital La Paz, Madrid, Spain, 6Hospital Vall Hebron, Barcelona, Spain, 7Janssen Infectious Disease BVBA, Beerse, Belgium, 8Bristol-Myers Squibb, Princeton, NJ, United States, 9Janssen Research and Development, Titusville, NJ, United States

Background: All-oral combinations of direct-acting antivirals offer potential for effective and well tolerated HCV therapies. We assessed the efficacy and safety of daclatasvir (DCV; NS5A inhibitor) combined with simeprevir (SMV; NS3/4A protease inhibitor), with or without ribavirin (RBV), in patients with HCV genotype (GT) 1 infection.

Methodology: In this open-label study (AI444-062), HCV GT1b treatment-naive patients (N=104) and prior null responders (N=43) were randomly assigned (1:1) to receive DCV 30mg QD + SMV 150mg QD or DCV + SMV + weight-based RBV, respectively (Table). SVR rates in GT1b null responders was 95% (19/20) with DCV + SMV + RBV and 65% (15/23) with DCV + SMV. Estimated SVR rates in GT1b (adjusted for pre-Week 12 discontinuations) were similar after 12 or 24 weeks of treatment in naive patients but higher after 12 than 24 weeks in null responders. In patients with GT1a, 8/12 (66.7%) naive patients achieved SVR and 7/9 (77.8%) null responders achieved SVR; all null responders were offered pegIFN/RBV + DCV + SMV rescue therapy due to frequent breakthroughs and were counted as failures. There were 2 treatment-related serious AEs (neurotoxicity, constipation, insomnia). 17 patients experienced grade 3/4 total bilirubin elevations without concurrent transaminase elevations, mostly in liver disorder) and 1 on-treatment death (unrelated intracranial hematoma). Three patients experienced treatment-related AEs leading to discontinuation (neurotoxicity, constipation, insomnia). 17 patients experienced grade 3/4 total bilirubin elevations without concurrent transaminase elevations, mostly in patients receiving RBV (14/17), consistent with RBV-induced hemolysis and known effects of SMV on bilirubin transporters.

Conclusions: The all-oral combination of DCV + SMV, with or without RBV, was generally well tolerated and achieved SVR in 75-85% of treatment-naive patients and 65-95% of prior null responders with GT1b infection after 12 or 24 weeks of treatment.

*IPW, Inverse Probability Weighting to adjust for patients who discontinued prior to Week 12 and were not re-randomized.
†All GT1a null responders were offered the addition of pegIFN alfa-2a as rescue therapy and are considered failures.

†Modified intention-to-treat analysis; includes all patients who received at least one dose of study medication.

As observed analysis excludes only patients with missing data at posttreatment Week 12

29LB PEARL III: SVR ≥99% After 12 Wks of ABT-450/r/267 + ABT-333 ± RBV in Treatment Naive HCV GT1b Infection

Peter Ferenci1, Anders Nyberg2, David Bernstein3, Yaacov Baruch4, Vladimir Chulanov5, Wangang Xie6, Daniel Cohen6, Thomas Podsadecki6, K Rajender Reddy7, on behalf of the PEARL-III Study Group

1Universitätsklinik fuer Innere Medizin III, Vienna, Austria, 2Kaiser Permanente, San Diego, CA, United States, 3North Shore University Hospital, Manhasset, NY, United States, 4Rambam Health Care Campus, Haifa, Israel, 5Federal Budget Institute of Science, Moscow, Russian Federation, 6AbbVie Inc., North Chicago, IL, United States, 7University of Pennsylvania, Philadelphia, PA, United States

Background: ABT-450 is an HCV protease inhibitor (dosed with ritonavir 100mg, ABT-450/r) identified by AbbVie and Enanta. ABT-267 is an NS5A inhibitor, and ABT-333 is a nonnucleoside polymerase inhibitor. Genotype 1b (GT1b) infection is more common globally than GT1a; thus there is a large unmet need for safe, efficacious and simple therapy. In a prior study, 100% of 50 treatment-naive subjects with GT1b infection who received this regimen for 12 weeks with or without ribavirin (RBV) achieved SVR. We report findings from a multinational phase 3 trial of co-formulated ABT-450/r/267 and ABT-333 (3D regimen), with and without RBV, in non-cirrhotic treatment-naive adults with GT1b HCV infection.
Methodology: PEARL-III was a double-blind controlled trial. Subjects were randomized (1:1) to 12 weeks of treatment with ABT-450/r/ABT-267 (150mg/100mg/25mg QD) and ABT-333 (250mg BID), with weight-based RBV (1000mg or 1200mg daily divided BID, Arm A) or placebo for RBV (Arm B).

Results: 419 subjects received the 3D regimen, baseline characteristics as shown (Table). SVR12 rates (intent-to-treat) were 99.5% (Arm A) and 99.0% (Arm B). There was no on-treatment virologic failure or post-treatment relapse among subjects receiving the 3D regimen without RBV. 19 subjects in Arm A and 0 in Arm B (P<0.001) had hemoglobin decrease to <10g/dL. The most common adverse events in Arms A and B were headache (24.3% vs. 23.4%, P=NS) and fatigue (21.4% vs. 23.0%, P=NS). No subjects discontinued due to adverse events.

Conclusions: In this large phase 3 trial, the 3D regimen was highly efficacious and safe with or without RBV for the treatment of HCV GT1b-infected non-cirrhotic treatment-naïve adults. RBV is not needed in this population.

NeuroHIV: Developments in Treatment and Pathogenesis

30 Early Antiretroviral Therapy Appears To Normalize Intrathecal Markers of Immune Activation
Julia Peterson1, Evelyn Lee1, Dietmar Fuchs2, Richard W. Price2, Serena Spudich1
1Neurology, University of California San Francisco, San Francisco, CA, United States, 2Innsbruck Medical University, Innsbruck, Austria, 3Neurology, Yale University, New Haven, CT, United States

Background: Central nervous system (CNS) viral invasion and accompanying neuroinflammation occur early after systemic HIV infection, and are a substrate for neurological injury in untreated disease. Markers of inflammation in the CNS have been shown to remain elevated in the presence of antiretroviral therapy (ART) initiated during chronic infection, yet the extent to which elevations may persist in the setting of treatment initiation early during infection is unknown. We investigated soluble and cellular markers of immune activation in the blood and cerebrospinal fluid (CSF) during primary HIV infection (PHI) and evaluated to what extent these markers may normalize after early ART initiation.

Methodology: 24 subjects with primary HIV infection (PHI, defined as <1 year HIV infection) had blood and CSF sampling at baseline and at a 6-12 month interval after starting ART. Subjects initiated ART at variable times after infection, for reasons independent of this protocol. To assess immune activation, we measured the following both at baseline and after ART initiation: CSF white blood cells (WBC), protein, CSF: plasma albumin ratio, CSF and blood neopterin. To investigate abnormality after early treatment initiation, PHI subjects were compared to a group of 20 age-matched HIV-uninfected subjects (HIV-) by Mann Whitney’s test. Additionally, baseline predictors of post-ART marker elevations were explored by Spearman’s correlation.

Results: At baseline, PHI subjects were 139 days post-infection (dpi) and 38 years old (all values medians). Most immune and inflammatory measures were abnormal in PHI compared to HIV- (p<0.01), including: CD4 count 507 cells/µL, CSF WBC 6 cells/µL, CSF neopterin 8.8 nmol/L, and plasma neopterin 13.89 nmol/L. Baseline CSF protein and CSF: plasma albumin ratio were different from HIV- Subjects started ART 532 dpi and had repeat sampling at 242.5 days after ART initiation. After ART, median values included: CSF WBC 2 cells/µL, CSF protein 36 cells/µL, CSF: plasma albumin ratio 4.57, CSF neopterin 4.95 nmol/L, and plasma neopterin 7 nmol/L. A significant elevation in PHI after sustained ART compared to HIV- was detected only in blood neopterin (p=0.03). Post-ART blood neopterin was predicted only by the number of days on ART (p=0.034, r=0.46), while post-ART CSF neopterin was predicted by baseline CSF and blood neopterin values (p=0.005, r=0.59 and p=0.029, r=0.47, respectively), as well as baseline albumin ratio (p=0.02, r=0.49).

Conclusions: In PHI subjects evaluated a median 8 months after ART was initiated 1.5 years after infection, levels of CSF markers of inflammation normalized. These findings are in contrast to prior reports of persistent CNS immune activation in chronic infection, and may suggest a benefit of early initiation of ART.

31 Immediate Antiretroviral Therapy Mitigates the Development of Neuronal Injury in Acute HIV
Michael J. Peluso1, Victor Valcour2, Jintanat Ananworanich2, Pasin Sitthimunsuwan1, Thep Chalermchai2, Nitya Chomche2, Bonnie Sike2, Magnus Gisslen2, Henrik Zetterberg2, Serena Spudich3, on behalf of the RV254/SEARCH 010 and 011 Study Teams
1Department of Medicine, Brigham and Women’s Hospital, Boston, MA, United States, 2Memory and Aging Center, University of California San Francisco, San Francisco, CA, United States, 3Neurology, Yale University, New Haven, CT, United States

Background: Neurofilament light chain (NFL) in cerebrospinal fluid (CSF) is a sensitive marker of axonal injury that is elevated in neurodegenerative disorders, HIV-associated dementia, and some neuroasymptomatic subjects during the early and late stages of HIV infection. We sought to determine whether axonal injury can be detected acutely after HIV transmission, and if initiation of combination antiretroviral therapy (cART) during acute HIV is associated with lower levels of CSF NFL compared to cART initiated during chronic HIV.

Methodology: PEARL-III was a double-blind controlled trial. Subjects were randomized (1:1) to 12 weeks of treatment with ABT-450/r/ABT-267 (150mg/100mg/25mg QD) and ABT-333 (250mg BID), with weight-based RBV (1000mg or 1200mg daily divided BID, Arm A) or placebo for RBV (Arm B).

Results: 419 subjects received the 3D regimen, baseline characteristics as shown (Table). SVR12 rates (intent-to-treat) were 99.5% (Arm A) and 99.0% (Arm B). There was no on-treatment virologic failure or post-treatment relapse among subjects receiving the 3D regimen without RBV. 19 subjects in Arm A and 0 in Arm B (P<0.001) had hemoglobin decrease to <10g/dL. The most common adverse events in Arms A and B were headache (24.3% vs. 23.4%, P=NS) and fatigue (21.4% vs. 23.0%, P=NS). No subjects discontinued due to adverse events.

Conclusions: In this large phase 3 trial, the 3D regimen was highly efficacious and safe with or without RBV for the treatment of HCV GT1b-infected non-cirrhotic treatment-naïve adults. RBV is not needed in this population.
**Methodology:** Acute (n=32) and chronic (n=33) HIV infected Thai subjects naïve to cART underwent blood and CSF sampling, followed by immediate cART initiation. CSF was then sampled at 24 (n=26) and 96 weeks (n=15) in the acute and at 48 weeks (n=10) in the chronic subjects. HIV RNA levels and soluble immune biomarkers were measured in CSF and blood at each visit. CSF NFL was analyzed using a highly sensitive, two-site enzymatic quantitative immunoassay with a lower limit of detection of 50 ng/L. Cross-sectional analyses employed the Mann-Whitney test and Spearman correlations; paired analyses were used to compare subjects across time points.

**Results:** At baseline (median 18 days post infection in acute subjects), median CD4 T cell count was 401 and 228 cells/µL in the acute and chronic groups, respectively (p<0.0001). Baseline CSF NFL was lower in acute than in chronic subjects (median, 234 versus 327 ng/L; p=0.003), and only 1/32 (3.1%) acute subjects had NFL above the upper limit of normal for age, compared to 10/33 (30.3%) chronic subjects. Baseline CSF NFL did not correlate with blood or CSF HIV RNA or soluble immune biomarkers in acute subjects, and modestly correlated only with the macrophage activation marker CSF neopterin in chronic subjects (r=0.35, p=0.049). In acute subjects, there was no change in NFL from baseline values to 24 and 96 weeks after cART. After at least 6 months of sustained cART (24 weeks duration of cART in acute cases and 48 weeks duration of cART in chronic cases), the acute group had a lower median CSF NFL than chronic subjects (216 vs 490 ng/L; p=0.015), and only 1/26 (3.9%) of acute subjects had CSF NFL above the upper limit of normal for age, compared to 5/24 (50%) in the chronic group.

**Conclusions:** Neuronal injury as measured by CSF NFL was not detected during very acute HIV infection. Immediate initiation of cART may mitigate development of neuronal injury, which may be more difficult to reverse during later stages of infection.

**32 Replication of HIV-1 in the Central Nervous System of Adults Early After Infection**

Christa Buckheit Sturdevant1, Gretja Schnell1, Richard W. Price2, Serena Spudich3, Ronald Swanstrom1

1UNC Chapel Hill, Chapel Hill, NC, United States, 2University of California San Francisco, San Francisco, CA, United States, 3Yale University, New Haven, CT, United States

**Background:** Viral replication within the central nervous system (CNS) facilitates neurological complications and reflects a potentially important tissue reservoir. The timing of emergence and character of this local CNS replication is unknown. We examined phylogenetic relationships and viral characteristics of paired cerebrospinal fluid (CSF) and blood samples obtained over the first two years of HIV infection.

**Methodology:** Subjects with primary HIV infection (PHI, <1 year after initial infection) were enrolled in San Francisco, USA, in a longitudinal neurological study including serial paired CSF and blood sampling. Using single genome amplification (SGA) and phylogenetic analysis of the full-length env gene, we compared viral populations from blood and CSF in samples obtained up to two years post-infection from 72 ART-naïve PHI subjects infected with HIV-1 subtype B.

**Results:** At baseline, subjects were a median 106 (IQR 73, 158) days post infection, had 567 (411, 732) CD4 T cells/µL, 4.66 (4.09, 5.08) plasma HIV RNA log10 copies/ml, and 2.62 (1.74, 3.32) CSF HIV RNA log10 copies/ml. Independent replication in the CNS (compartmentalization) was detected in 12% of all sample pairs, predominantly after four months of infection. Approximately 20% of the time there was either compartmentalization or marked pleocytosis, which we propose are dynamic and interrelated. Longitudinal assessment of individual subjects demonstrated that compartmentalized replication was present either as a transient state, or was maintained within the CSF and diversified independently over a period of time during early infection. Two subjects had one of two transmitted lineages (or their recombinant) largely sequestered within the CNS shortly after transmission, indicating a second mechanism for establishing independent replication in the CNS early. All viruses examined required high levels of CD4 for entry, indicative of replication in CD4+ T cells.

**Conclusions:** Examination of the relationships between CSF viral populations, blood and CSF viral loads, and inflammatory responses identified four distinct states of viral population dynamics, and revealed putative mechanisms of local viral replication and the early influx of virus into the CNS. We observed genetically complex, compartmentalized viral replication within the CSF/CNS suggestive of sustained replication in CD4+ T cells during the first two years of HIV infection.

**33 Persistent CSF, But Not Plasma HIV RNA Is Associated With Increased Risk of New-Onset Depression**

Edward R. Hammond1, Rosa M. Crum2, Glenn J. Treisman1, Shruti H. Mehta1, Ronald J. Ellis2, Igor Grant1, Scott L. Letendre1, Christina M. Marra1, Susan Morgello3, Justin C. McArthur1

1The Johns Hopkins University, Baltimore, MD, United States, 2University of California San Diego, San Diego, CA, United States, 3University of Washington, Seattle, WA, United States, 4Icahn School of Medicine at Mount Sinai, New York, NY, United States

**Background:** Major depressive disorder is the most common neuropsychiatric complication in persons with HIV and is associated with worse clinical outcomes. It is unknown whether detectable cerebrospinal fluid (CSF) human immunodeficiency virus (HIV) ribonucleic acid (RNA) at thresholds ≥50 copies/ml is associated with increased risk of new-onset depression. We hypothesized a priori that detectable CSF HIV RNA is associated with increased risk of depressive symptoms and increasing depression scores.

**Methodology:** The CNS HIV Anti-Retroviral Therapy Effects Research (CHARTER) cohort is a six-center US-based prospective cohort with bi-annual follow-up 674 participants. We fit linear mixed models (N=223) and discrete-time survival models (N=154), a total of 832 observations, among participants on combination antiretroviral therapy (cART) enrolled from 2004 to 2007, and followed through 2009 over 2,496 person-months. Participants were included in these analyses if they were free of depression at study entry and received a minimum of three CSF exams during follow-up. The main outcome measures were incidence of new-onset moderate-to-severe depressive symptoms (BDI ≥17), and trajectories of BDI scores.
Results: The mean age was 44.8 years, majority were male (81.6%), 44.8% Black, 39.5% White, and mean duration of current cART use was 18.1 months. At study entry, 32 (14.4%) participants had detectable CSF HIV RNA (≥50 copies/ml). Detectable CSF HIV RNA at any visit was associated with a 4.7-fold increase in new-onset depression at subsequent visits adjusted for plasma HIV RNA and treatment adherence; hazard ratio (HR)=4.76, (95% CI: 1.58-14.33); P=0.006. BDI scores were 2.53 points higher (95% CI: 0.47-4.60; P=0.02) over 6 months if CSF HIV RNA was detectable at a prior study visit in fully adjusted models including age, sex, race, education, plasma HIV RNA, duration and adherence of cART, and lifetime major depressive disorder by Diagnostic Statistical Manual of Mental Disorders, Fourth Edition criteria. Throughout follow-up in adjusted linear mixed models, BDI scores for persons with detectable CSF HIV RNA increased, whereas BDI scores decreased when CSF HIV RNA was undetectable. Unlike the findings for CSF HIV RNA, plasma HIV RNA was not associated with an increase in BDI scores over time.

Conclusions: Persistent CSF but not plasma HIV RNA is associated with an increased risk for new-onset depression. Persons with persistent or worsening depression may benefit from CSF testing for HIV RNA, which may help guide HIV and depression treatment. Further research evaluating the role of immune activation and inflammatory markers will improve our understanding of this association. We speculate that depression may be a surrogate of ongoing CNS inflammation and injury.

34 CSF Metabonomics Reveals Altered Waste Clearance and Accelerated Aging in HIV Patients With HAND
Edana Cassol1, Vikas Misra1, Anupriya Dutta1, Susan Morgello2, Dana Gabuzda1
1Cancer Immunology and AIDS, Dana-Farber Cancer Institute, Boston, MA, United States, 2The Mount Sinai Medical Center, New York, NY, United States

Background: HIV-associated neurocognitive disorders (HAND) remain prevalent in HIV-infected populations on antiretroviral therapy (ART). Factors associated with increased risk of HAND in HIV patients on suppressive ART include older age, low nadir CD4, and active HCV co-infection, but underlying pathophysiological mechanisms remain unclear.

Methodology: Untargeted metabolite profiling of cerebrospinal fluid (CSF) from 90 subjects (36 HIV+ subjects on ART from CHARTER and NNTC [median CD4 count 141 cell/μl, median plasma VL 268 copies/ml, median CSF VL 50 copies/ml; n=17 and 19 with and without HAND [median global T-scores 36 and 48, respectively]) and 54 healthy controls [ages 30-78]) was performed using liquid or gas chromatography followed by mass spectrometry. Cytokine profiling was performed by Bioplex array. Pathway mapping and PLS-DA, were performed using Metaboanalyst and Cytoscape. Integrative analysis of CSF metabolites, cytokines, and global and domain-specific T-scores was performed in R.

Results: Of 107 named metabolites detected in CSF, 20 were altered in HIV+ subjects on ART compared to age/gender-matched healthy controls (FC>1.2, p<0.05, FDR<5%) including metabolic waste products (ketone bodies, phenylacetylglutamine, p-cresol sulfate), neurotransmitters (glutamate, NAA), and markers of mitochondrial dysfunction (3-dehydrocarnitine, succinate, malate) and oxidative stress (5-oxoproline and purine metabolites). 53% of metabolites altered in HIV subjects (< age 50) overlapped with those altered in aging healthy controls (≥ age 50 vs. < age 50), including glutamate, succinate, ketone bodies, and phenylacetylglutamine, suggesting a pattern indicative of accelerated aging. Fold change and PLS-DA analysis identified glutamate, glycine, succinate, ketone bodies (3-hydroxybutyrate, acetoacetate, and 1,2 propanediol), and myo-inositol as top-ranked classifiers of HAND. Integrative analysis of cytokine, metabolic, and clinical data revealed positive correlations (p<0.05, FDR<10%) between persistent elevation of CSF IFN-γ and IL-8, plasma IFN-γ and IL-6, and a metabolite clusters consisting of neurotransmitters (glutamate and glycine), ketone bodies (3-hydroxybutyrate and 1,2 propanediol), and markers of glial responses (myo-inositol), and suggested associations between systemic and intrathecal inflammation, metabolic alterations in CSF that overlap those detected in older controls, and classifiers of HAND.

Conclusions: Alterations in the CSF metabolome of HIV patients on ART suggest that persistent inflammation, glial responses, glutamate/glycine neurotoxicity, and age-dependent effects on brain waste-disposal systems contribute to mechanisms involved in development of HAND that may be augmented with aging.

35 Cerebral Small Vessel Disease and HAND in ARV-Treated Subjects
Virawudh Soontornniyomkij, Anya Umlauf, Benchawanna Soontornniyomkij, Ben Gouaux, Will Toperoff, David J. Moore, Eliezer Masliah, Igor Grant, Cristian L. Achim
UC San Diego, San Diego, CA, United States

Background: Despite the widespread use of highly active antiretroviral therapy, HIV-associated neurocognitive disorders (HAND) remain prevalent and may be associated with cumulative exposure to antiretroviral (ARV) medications and other factors. We proposed that chronic toxic effects of ARV drugs on the blood vessel walls could contribute to cerebral small vessel disease (CSVD), which even at its early stages could lead to disturbance of cerebrovascular autoregulation and deficiency in functional hyperemia.

Methodology: We assembled 144 consecutive autopsy HIV-infected cases that had detailed data on ARV medications ever used during the entire period of follow-up observation and died during 1999–2011. In studying associations between the use of ARV drugs and the occurrence of blood vessel pathology in the brain, we included three major drug classes: nucleoside reverse transcriptase inhibitors (NRTIs), non-nucleoside reverse transcriptase inhibitors (NNRTIs), and protease inhibitors (PIs). We employed multinomial logistic regression to determine associations between the use of ARV drugs and the occurrence of CSVD. Forebrain CSVD was defined as concentric intramural hyalinization of small arteries or arterioles in the forebrain leptomeninges and parenchyma. CSVD was graded as absent, mild, or severe.

Results: Mild CSVD was present in 24.8% and severe CSVD in 47.4% of 137 cases. On multinomial logistic regression analysis, the use of NRTIs or PIs was associated with the higher odds of mild CSVD (relative to absent) [OR 19.23 and 2.84, P=0.003 and =0.06, respectively]. No association was found between mild CSVD and any of the potential covariates. In contrast, the occurrence of severe CSVD (relative to absent) was associated with older age or...
diabetes (OR 2.56 and 6.55, P=0.035 and =0.01, respectively), but not with any of the ARV-related predictors. Notably, HAND was associated with mild CSVD (OR 4.82). No other significant associations between pathologic changes and HAND were found.

**Conclusions:** The clinical importance of mild CSVD in our study was substantiated by the finding that mild CSVD was predictive of HAND. Our findings suggest that the use of NRTIs or PIs may increase the risk of mild CSVD and consequently neurocognitive impairment. Interestingly, we found no significant association between the use of any ARV drug classes during life and the presence of HIV encephalitis at autopsy. Although our study analyzed the adverse effects of individual major ARV drug classes, different ARVs drugs even in the same class might carry differential degrees of toxicity on cerebral vessels. We are pursuing now studies of the molecular mechanisms of ARV toxicity to the cell components of cerebral vessels and identification of potential biomarkers for CSVD in HIV-infected patients.

### 36 Temporal Trends in Prognostic Markers of HIV-1 Virulence and Transmissibility

**Nikos Pantazis**1, Khoudou Porter1, Dominique Costagliola1, Andrea De Luca1, Jade Ghozzi1, Marguerite Guiguert1, Anthony D. Kelleher3, Charles Morrison7, Rodolphe Thiebaut2, Giota Touloumi1, on behalf of the CASCADE Collaboration in EuroCoord

1Hygiene, Epidemiology & Medical Statistics, Athens University Medical School, Athens, Greece, 2MRC Clinical Trials Unit at University College London, London, United Kingdom, 3INSERM U943, Université Pierre et Marie Curie - Paris 6, UMR S 943, Paris, France, 4Institute of Clinical Infectious Diseases, Università Cattolica del Sacro Cuore, Roma, Italy, 5Internal Medicine and Infectious Diseases, Bicetre University Hospital, Kremlin Bicetre, Paris, France, 6Kirby Institute, University of New South Wales, Sidney, Australia, 7FHI 360, Durham, NC, United States, 8INSERM U897 Centre of Epidemiology and Biostatistics, ISPED Bordeaux School of Public Health, University Bordeaux Segalen, Bordeaux, France

**Background:** Measures of CD4 T-cell count (CD4) and HIV-1 plasma viral load (pVL) are proxies for HIV-1 virulence. Whether these proxies are changing over time has serious implications for prevention and treatment. The aim of this study is to investigate these trends.

**Methodology:** Data were derived from the CASCADE collaboration (updated in 2011) excluding African cohorts, recent seroconverters (≥2009) and children <15 years old at seroconversion (SC). Follow-up was censored at the time of antiretroviral initiation or clinical AIDS onset. CD4 at SC, CD4 rate of decline and pVL measurements were analyzed using linear or fractional polynomials mixed models adjusting for all available potential confounders. Calendar time effects were modelled through natural cubic splines.

**Results:** 15,875 individuals seroconverting from 1979-2008 fulfilled the inclusion criteria. Estimated (95% CI) CD4 at SC for a typical individual declined from ~770 (750-800) in the early ’80s to a plateau of ~570 (560-580) cells/μL after 2000. Rates of CD4 loss were relatively stable up to 1996 becoming faster between 1996 and 2004. Estimated (95% CI) pVL set-point increased from 4.05 (3.98-4.12) in 1980 to 4.50 (4.45-4.54) log10 copies/mL in 2002 with a tendency of returning to lower levels thereafter. Estimated (95% CI) CD4 at SC and pVL set-point for white men, infected through sex between men (MSM), aged 30-39 years at seroconversion are shown in Figure (a and b, respectively). Results were similar when restricting the analyses to various subsets (e.g. those with a ‘midpoint’ method of seroconversion determination and a test interval <180 days; white MSM etc.), adjusting for pVL assay, censoring follow-up at 3 years or using variations of the main statistical approach.

**Conclusions:** Our results provide strong indications of an increased HIV-1 virulence and transmissibility during the course of the epidemic and a potential plateau effect after ~2000. Continued monitoring and basic science studies are needed to detect further virulence changes and to assess the consistency of our findings.
37  Transmission Clusters, Recent Infection and STIs Among New HIV Cases: Implications for Prevention
Hong-Ha M. Truong1-4, Sharon Pipkin5, Kara O’Keefe6, Brian Louie7, Teri Liegler1, Willi McFarland1,8, Robert M. Grant1,2, Mark Pandori3, Kyle Bernstein2, Susan Scheer3
1University of California San Francisco, San Francisco, CA, United States, 2Gladstone Institute of Virology and Immunology, San Francisco, CA, United States, 3Department of Public Health, San Francisco, CA, United States

Background: Only HIV transmission that is occurring in the present can be interrupted. Recent infection, a new diagnosis of a sexually transmitted infection (STI) and phylogenetically-linked transmission clusters are factors that may help direct prevention efforts towards current chains of HIV transmission. We therefore examined correlates associated with recent and longer-standing infection among persons newly-diagnosed with HIV in San Francisco.

Methodology: San Francisco residents newly-diagnosed with HIV from 2005 through 2011, linked to care at publicly-funded facilities and had viral genotypes included in the analysis. This study received IRB approval. Transmission clusters were identified based on bootstrap values of $\leq 0.03\%$. Recent HIV infection was defined as having a documented negative antibody test within 6 months of HIV diagnosis and/or being acutely infected (RNA+/Ab-). A recent STI diagnosis was defined as being diagnosed with a new STI within the 6 months preceding HIV diagnosis. Associations were assessed by multivariate logistic regression.

Results: Overall, there were 1,311 persons newly-diagnosed with HIV, of whom 45% were part of a transmission cluster, 16% were recently infected and 12% had a recent STI diagnosis. Demographically, 57% were non-white, 32% were under 30 years old and 76% were MSM. Among persons recently infected with HIV, 57% were linked to a transmission cluster, 25% had a recent STI diagnosis, 56% were non-white, 44% were under 30 years old and 86% were MSM. Individuals with recent HIV infection were more likely to belong to a transmission cluster (OR=1.8; p<0.001), have a recent STI diagnosis (OR=2.5; p<0.001) and be under 30 years old (OR=2.7; p<0.01) than persons with longer-standing infections.

Conclusions: These findings help to pinpoint where HIV transmission continues to propagate in San Francisco, including highlighting that many newly-diagnosed infections are participating in phylogenetically-linked transmission chains. Recent HIV infection was associated with being diagnosed with a STI during the time interval that overlapped with when HIV transmission most likely occurred, thereby pointing to intervention opportunities to interrupt HIV transmission. The high rate of clustering observed indicates that recent infections may be associated with increased risk of onward transmission of HIV but also suggests these individuals may be reached to prevent the further spread of infections.

38  Race and Age Disparities in HIV Incidence and Prevalence Among MSM in Atlanta, GA
Eli S. Rosenberg1, Patrick S. Sullivan1, Colleen F. Kelley1, Travis H. Sanchez1, Nicole Luisi1, Carlos del Rio1, Laura F. Salazar1, Paula F. Frew1, John L. Peterson2
1Epidemiology, Emory University Rollins School of Public Health, Atlanta, GA, United States, 2Infectious Diseases, Emory University School of Medicine, Atlanta, GA, United States

Background: HIV prevalence and incidence race disparities exist among US men who have sex with men (MSM); individual-level risk factors do not explain these differences.

Methodology: InvolveMENt is a longitudinal cohort of black (BMSM) and white (WMSM) HIV-negative MSM aged 18-39, recruited via venue time-space sampling. Eligible men reported any sex with a man in the previous 3 months. Every 3-6 months, participants were tested for HIV/STI and completed CASI surveys of individual- and sexual dyad-level risk behaviors. Race- and age-specific HIV and STI prevalence, prevalence-ratios (PR), incidence rates and incidence-density ratios (IDR) were estimated with exact 95% confidence intervals (CI). Age-scaled Cox proportional hazards estimated time-independent and -dependent mediators of disparate HIV incidence.

Results: 803 MSM (454B, 349W) were enrolled: 197 BMSM and 46 WMSM were HIV-positive at baseline. Except for 18-19 year olds, BMSM had higher HIV prevalence than WMSM (BMSM: 34% at 25 years, 45% by 30 years, 60% at 30 years). In 755 person-years (PY) of followup, 23 incident HIV infections were diagnosed (19 BMSM, 4 WMSM). Among participants < 25 years, HIV incidence for BMSM was 9.6% and 0% for WMSM (RR undefined but > 2.1 (95% CI: [2.1, +∞])). Among participants ≥ 25 years, HIV incidence was nonsignificantly higher for BMSM (3.4%) than WMSM (1.2%); IDR = 2.8 (CI: [0.7, 13.1]). Compared to BMSM ≥ 25 years, those < 25 had significantly higher incidence (RR = 2.9; CI: [1.1, 7.7]). Similar significant disparities were found for urethral gonorrhea, rectal chlamydia, rectal gonorrhea, and syphilis incidence. Results from a change-in-hazard approach found that the racial disparity in HIV incidence was explained by poverty and partner race, but not employment, inverse vs. receptive sex roles, drug use, and time-dependent homelessness, arrest, anal intercourse, and known serodiscordant partners (unadjusted HR: 5.4, CI: [1.8, 16.6]; adjusted HR: 1.4, CI: [0.4, 5.5]).

Conclusions: Relative to WMSM, BMSM in Atlanta experience substantially higher HIV and STI incidence. Nearly 1 in 10 black MSM under age 25 is infected with HIV annually. Observed incidence levels are consistent with large observed prevalence disparities and highlight the 18-24 year period as critical for prevention, and that educational and other prevention services need to start before 18. It is critical to identify mechanisms, such as choice of sexual partners and access to clinical and prevention services, through which poverty shapes other risks. In a setting where partner pool risk is a driver of disparities, it is also important to maximize care and treatment for HIV-positive MSM to reduce transmission potential.

39  Correlating GSK1265744 Plasma Levels To Prevention of Rectal SHIV Transmission in Macaques
Chasity D. Andrews1, William Speeren2, Yun Lan Yueh2, Agegnehu Gettle2, Kasi Russell-Lodrigue3, Hiroshi Mohri1, Cecilia Cheng-Mayer1, Zhi Hong4, Martin Markowitz1, David D. Ho1
1Aaron Diamond AIDS Research Center, The Rockefeller University, New York, NY, United States, 2GlaxoSmithKline, Research Triangle Park, NC, United States, 3Tuana National Primate Research Center, Covington, LA, United States

Background: GSK1265744 (GSK744) is an INSTI with properties permitting formulation as a long-acting (LA) injectable nanoparticle suspension (200 mg/mL). We reported at CROI 2013 that GSK744LA is effective as PrEP against repeated low-dose intrarectal (IR) SHIV exposures in 8 male rhesus macaques
Oral Abstracts

Methodology: Twelve male RM were injected IM with 50 mg/kg GSK744LA one week prior to the first challenge. Four RM remained untreated as placebo controls, with 1 placebo RM beginning challenge every four weeks. All animals were challenged IR each week with SHIV162P3 (50 TCID50) until infection was established. Infection status was monitored by real-time PCR amplification of viral gag sequences from plasma obtained weekly. We assumed a two-week eclipse phase between infection and virus detection. Plasma GSK744 levels were measured by HPLC-MS/MS.

Results: Of the 12 GSK744LA-treated RM, none had detectable systemic viremia following the first 4 weekly challenges confirming that monthly administration of GSK744LA protects an additional 12 male RM against repeated IR SHIV challenges. GSK744LA-treated RM became infected after 6 to 17 challenges compared with 1 to 7 challenges for the 12 placebo controls (4 current and 8 historical). One dose of GSK744LA delayed infection by 5 to 10 (median 8) challenges compared with untreated RM. GSK744 plasma levels are reported at the time of infection. The percent of challenges resulting in infection were calculated relative to the plasma GSK744 protein-adjusted IC90 (PAIC90) value. None of 59 challenges resulted in infection when plasma levels were >3X PAIC90, compared with 1 of 22 challenges when plasma levels were between 1X to 3X PAIC90, and 11 of 43 challenges when plasma levels were <1X PAIC90 (see figure). 12 of 26 challenges resulted in infection in placebo RM.

Conclusions: We have shown that GSK744LA can protect 20/20 male RM against repeated IR SHIV challenges. Furthermore, GSK744 plasma concentrations >3X PAIC90 result in 100% protection while the efficacy appears to be 97% at plasma levels ≥1X PAIC90. These plasma levels of GSK744 can be readily achieved in man with quarterly 800 mg IM injections. Phase 2 evaluations of GSK744LA as PrEP will initiate in 2014 in anticipation of Phase 3 efficacy trials.

40LB Monthly GSK744 Long-Acting Injections Protect Macaques Against Repeated Vaginal SHIV Exposures
Jessica Radzio1, William Spreen2, Yun Lan Yueh2, James Mitchell1, Leecresia Jenkins1, J. Gerardo Garcia-Lerma1, Walid Heneine1
1Division of HIV/AIDS Prevention, CDC, Atlanta, GA, United States, 2GlaxoSmithKline, Research Triangle Park, NC, United States

Background: Pre-exposure prophylaxis (PrEP) with long-acting antiretroviral drugs has the potential to overcome the challenges of adherence associated with daily PrEP. The HIV integrase inhibitor GSK1265744 has been formulated as a long-acting injectable nanosuspension (GSK744 LA) and is an attractive candidate for PrEP. We used a pigtail macaque model to investigate systemic and vaginal GSK744 LA pharmacokinetics (PK) and evaluate efficacy against vaginal SHIV infection. This model assesses PrEP under physiologic conditions because pigtails have menstrual cycles similar to women, do not require the use of depo Provera to ensure vaginal infection, and can be infected with lower and more physiologic virus doses.

Methodology: Drug PK was evaluated in plasma and vaginal secretions from 6 macaques receiving two intramuscular (IM) injections of GSK744 LA (50 mg/kg) administered 4 weeks apart. The prophylactic efficacy of GSK744 LA was investigated in macaques repeatedly challenged with SHIV. Macaques received GSK744 LA (n = 6) or placebo (n = 6) IM every 4 weeks (total of 3 injections), and were concurrently exposed twice a week to low (50 TCID50) doses of SHIV. Infection was monitored by serology and PCR amplification of SHIV RNA and proviral DNA.

Results: Peak plasma drug concentrations (Cmax = 3,753 ng/ml; range = 2,488-9,903) were within the range reported in humans receiving 400 mg IM, with levels remaining above the protein adjusted IC90 (166 ng/ml) for a median of 49 days (range = 28->63) after the last dose. Peak GSK744 concentrations in vaginal secretions (911 ng/ml; range = 427-1,877) were lower than in plasma. Area under the curve values over 28 days were also lower in vaginal secretions (11,511 ng*day/ml; range = 3,956-14,011) relative to plasma (70,333 ng*day/ml; range = 40,265-169,341). All 6 macaques receiving GSK744 LA remained seronegative and viral RNA and DNA negative during the 22 SHIV challenges and 12 weeks after the last GSK744 LA injection. In contrast, all 6 controls were SHIV RNA positive after a median of 4 (range = 2-20) exposures (p<0.001).

Conclusions: We show that single, monthly injections of GSK744 LA that reproduce the human dose fully protect macaques against repeated vaginal SHIV exposures. The high protection seen despite lower vaginal drug concentrations suggest a contribution of mucosal and systemic GSK744 to the observed protection. These data support advancement of GSK744 LA as a PrEP candidate for women.
**41** **Safety and Pharmacokinetics/Pharmacodynamics of Dapivirine and Maraviroc Vaginal Rings**

Beatrice A. Chen¹, Lori Panther², Craig Hoesley³, Craig Hendrix⁴, Ariane van der Straten², Marla Husni², Lydia E. Soto-Torres⁴, Annalene Nel⁵, Sherri Johnson⁶, Charlene S. Dezzutti⁷

¹University of Pittsburgh, Pittsburgh, PA, United States, ²The Fenway Institute, Boston, MA, United States, ³University of Alabama at Birmingham, Birmingham, AL, United States, ⁴The Johns Hopkins University, Baltimore, MD, United States, ⁵RTI International, San Francisco, CA, United States, ⁶Statistical Center for HIV/AIDS Research & Prevention, Fred Hutchinson Cancer Research Center, Seattle, WA, United States, ⁷NIAID/DAIDS, Bethesda, MD, United States, ⁸International Partnership for Microbicides, Silver Spring, MD, United States, ⁹FH 360, Research Triangle Park, NC, United States, ¹⁰Magee-Women’s Research Institute, Pittsburgh, PA, United States

**Background:** Vaginal rings offer sustained multi-drug delivery for pre-exposure prophylaxis of HIV infection. A dapivirine (DPV) vaginal ring, an NNRTI, is in Phase III trials. Maraviroc (MVC), a CCR5 co-receptor antagonist, is approved for oral HIV treatment but has not been studied intravaginally. This trial evaluated the safety and pharmacokinetic/pharmacodynamics of vaginal rings containing DPV and MVC alone or in combination compared to placebo.

**Methodology:** We conducted a multi-site, double-blind, randomized, placebo-controlled trial in 48 HIV-negative sexually abstinent women to evaluate vaginal rings containing 25 mg DPV plus 100 mg MVC, DPV only, MVC only or placebo used for 28 days followed by 24 days off product. Safety was assessed by adverse events (AE). Adherence was assessed by self-report and residual drug levels in returned rings. DPV and MVC plasma and vaginal fluid levels were quantified. Cervical biopsies were obtained on day 28 immediately after ring removal to quantify drug and for the HIV ex vivo challenge assay.

**Results:** Mean age was 29.6 years (range 20-40); 50% were white and 38% were black. Retention was 98% at the final visit. There were 33 grade 1 and one grade 2 related genitourinary AEs from 22 women with no difference between each of the treatment arms and placebo arm. There were 20 grade 2 or higher AEs from 13 women, of which two grade 2 AEs were related to study product. Ninety-four percent were fully adherent by self-report; ring use was confirmed by residual drug levels. Plasma DPV Cmax was not significantly different between DPV and DPV/MVC users (272 vs 294 pg/μL, respectively). MVC plasma concentrations were below limits of quantification (LOQ). Day 28 mean DPV vaginal fluid levels were 14.9 μg/mL and 10.0 μg/mL in DPV and DPV/MVC users, respectively. Day 28 mean DPV tissue levels were 0.6 μg/mL and 1.6 μg/mL in DPV and DPV/MVC users. Day 28 mean MVC vaginal fluid levels were 6.7 μg/mL and 1.1 μg/mL in MVC and DPV/MVC users. Only 4 of 24 MVC and DPV/MVC users had tissue levels above LOQ for MVC. Fresh cervical tissue from DPV and DPV/MVC users showed a significant inverse linear relationship between HIV replication and tissue DPV drug levels.

**Conclusions:** Vaginal rings were safe and well tolerated. DPV but not MVC delivered by a vaginal ring for 28 days blocked HIV-1 infection in cervical tissue. There was a linear correlation between DPV levels in tissue and protective effect. These data suggest that delivery of NNRTIs via vaginal rings is a viable approach for HIV prevention.

**Day 11 of Ex vivo challenge culture**

---

**42LB** **FAME-02: A Phase I Trial To Assess Safety, PK, and PD of Gel and Film Formulations of Dapivirine**

Katherine E. Bunge¹, Charlene S. Dezzutti², Ingrid Macci³, Craig W. Hendrix³, Lisa C. Rohan³, Mark A. Marzinke⁴, Brid Devlin⁴, Leslie A. Meyn², Hans M. L. Spiegel⁵, Sharon L. Hillier¹

¹Department of Obstetrics, Gynecology and Reproductive Sciences, University of Pittsburgh, Pittsburgh, PA, United States, ²Magee-Womens Research Institute, Pittsburgh, PA, United States, ³Department of Medicine, The Johns Hopkins University, Baltimore, MD, United States, ⁴International Partnership for Microbicides, Silver Spring, MD, United States, ⁵Division of AIDS, National Institutes of Health, Bethesda, MD, United States

**Background:** Film formulations of topical microbicides have theoretical advantages over gels and intravaginal rings. Relying on physiologic fluids to dissolve, the product may provide more efficient drug delivery while minimizing disruption of innate immune defenses, product application may ensure privacy while avoiding leakage, and the cost associated with scale up of vaginal films compares favorably to gels. In this first in human trial of a film for delivery of ARVs, we sought to compare the safety, PK, and PD of film and gel formulations of dapivirine versus placebo.

**Methodology:** 60 healthy HIV negative women were randomized to placebo gel, dapivirine (0.05%) gel, placebo film, or dapivirine (1.25mg) film. Participants were instructed to use product daily for seven days. Adverse event (AE) data were collected via questionnaire and physical exam at two follow-up visits. The proportion of participants experiencing Grade 2 and higher AEs deemed related to study product were compared across treatment arms using Fisher’s exact
test. After seven daily doses plasma dapivirine levels were measured. Cervical and vaginal biopsies obtained 2-4 hours after the last dose were analyzed for tissue drug levels or were exposed to HIV-1 in an ex-vivo challenge model. Tissue HIV infection was monitored by p24 levels in culture supernatant.

Results: The mean age of the participants was 26.7 years; 53.3% of evaluable participants were white and 36.7% black. There were two Grade 2 related AEs; both were in the placebo film group. Five of 29 women assigned to film were noted to have visible film at or outside of the introitus just prior to biopsies which suggested poor film placement; all were in the active film arm. Women randomized to gel and film products had comparable plasma dapivirine levels (302.47 vs 227.13 pg/ml) after one week. However, tissue levels of dapivirine were 4 times higher in the gel users when compared to film users, possibly due to residual gel product adherence to the tissue surface. Both active products when placed correctly were protective against HIV-1 infection in the ex-vivo challenge model (Figure 1).

Conclusions: This proof of concept study demonstrated that the dapivirine film was safe and released dapivirine to plasma and genital tissue at levels comparable to the dapivirine gel and intravaginal ring. While safe and effective when placed correctly, the dapivirine film was difficult to insert for some women, and further development is needed to optimize ease of placement for this dosage form.

43 Single-Agent TDF Versus Combination FTC/TDF PrEP Among Heterosexual Men and Women

Jared Baeten1, Deborah Donnell1-2, Patrick Ndase1, Nelly Mugo1-3, Connie Cemus1, Partners PrEP Study Team
1University of Washington, Seattle, WA, United States, 2Fred Hutchinson Cancer Research Center, Seattle, WA, United States, 3Kenya Medical Research Institute, Nairobi, Kenya

Background: Antiretroviral pre-exposure prophylaxis (PrEP), using daily oral tenofovir (TDF) alone or combination emtricitabine/tenofovir (FTC/TDF), has been demonstrated to be an efficacious HIV-1 prevention intervention in four clinical trials. Whether single-agent TDF PrEP has comparable efficacy to dual-agent FTC/TDF PrEP is unknown.

Methodology: The Partners PrEP Study was a randomized, double-blind, placebo-controlled three-arm trial of daily oral TDF and FTC/TDF PrEP among heterosexual HIV-1 uninfected members of HIV-1 serodiscordant couples from Kenya and Uganda. In July 2011, the trial’s placebo arm was discontinued because of clear demonstration of HIV-1 protection from PrEP; compared to placebo, HIV-1 prevention efficacy was 67% for TDF and 75% for FTC/TDF, and TDF and FTC/TDF efficacy were not significantly different (p=0.23). After July 2011, to gather additional comparative information about single-versus dual-agent PrEP, the trial’s active arms were continued in a blinded fashion and the participants initially randomized to placebo were offered re-randomization to TDF or FTC/TDF PrEP. Data collection was completed in December 2012.

Results: 4747 HIV-1 serodiscordant couples were enrolled and followed; for 62%, the HIV-1 uninfected partner was male. A total of 52 post-randomization HIV-1 infections occurred among individuals assigned to the active PrEP arms; 30 prior to and 22 after July 2011. Of these 52 infections, 31 were among those assigned TDF (incidence 0.7 per 100 person-years) and 21 were among those assigned FTC/TDF (incidence 0.5 per 100 person-years); for comparison, HIV-1 incidence in the placebo arm prior to July 2011 was 2.0 per 100 person-years. HIV-1 prevention efficacy for FTC/TDF compared to TDF alone was not statistically significantly different: HR 0.67, 95% 0.39-1.17, p=0.16. Detection of tenofovir in plasma samples, measured in seroconverters and a subset of non-seroconverters, was associated with an 85% relative risk reduction in HIV-1 acquisition for the TDF arm and 93% for the FTC/TDF arm (both p<0.001). By consensus sequencing, no cases of HIV-1 antiretroviral resistance related to TDF or FTC were identified in HIV-1 seroconverters after July 2011.

Conclusions: Among heterosexual men and women, once-daily oral TDF and FTC/TDF are safe and provide high and comparable risk reduction against HIV-1 acquisition.

44 Divergent Adherence Estimates With Pharmacokinetic and Behavioral Measures in VOICE (MTN003)

Ariane van der Straten1, 2, Elizabeth R. Brown1, 2, Jeannie M. Marrazzo1, Zvavahera M. Chirenje1, Kaizifang Guo3, Jeanne M. Piper4, Craig W. Hendrix5
1Women’s Global Health Imperative, RTI International, San Francisco, CA, United States, 2Department of Medicine, Center for AIDS Prevention Studies (CAPS), University of California San Francisco, San Francisco, CA, United States, 3Statistical Center for HIV/AIDS Research & Prevention (SCHARP), Fred Hutchinson Cancer Research Center, Seattle, WA, United States, 4Department of Medicine, Division of Infectious Diseases, University of Washington, Seattle, WA, United States, 5Department of Obstetrics and Gynecology, University of Zimbabwe, Harare, Zimbabwe, 6FHI 360, Research Triangle Park, NC, United States, 7Division of AIDS, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

Background: The level of protection conferred by tenofovir (TFV)-based PrEP correlates with product adherence in some studies. In VOICE, daily oral tenofovir disoproxil fumarate (TDF), oral TDF-emtricitabine (FTC), and 1% vaginal TFV gel were not effective and poor adherence was determined based on plasma TFV detection in a subset of participants in the active product random pharmacokinetic (PK) cohort. We compare behavioral measures of adherence to (PK) assessment of TFV in plasma and vaginal swabs.

Methodology: From 9/2009 to 8/2012, 5029 HIV-negative, sexually active, non-pregnant women were enrolled and followed up to 36 months at 15 sites in South Africa, Uganda and Zimbabwe. Adherence assessments included face-to-face interviews (FTI; assessed frequency of product use, past 7 days) and clinic product counts (CPC) conducted monthly; audio-computer assisted self-interview (ACASI; frequency of product use, past 7 days) and 6 point rating scale (very low to excellent, past 4 weeks) conducted quarterly. Plasma concentration < 0.3 ng/mL in oral arms and vaginal swab < 8.5 ng/swab in gel arm correspond with no product use in the past week, and were defined dichotomously as “PK non-adherent”. We randomly selected one single quarterly visit for each participant from the random PK cohort (visit range: 3-24 months). Logistic regression models were fit to calculate the combined predictive ability of the behavioral measures as summarized by the area under the ROC curve (AUC).

Results: Of 472 participants in the random subset, 314 were in the active oral arms and 158 in the TFV gel arm. Mean age was 25.4 years, 79% were unmarried, and 79% had a main male sex partner; 79%, 14% and 7% were from South Africa, Zimbabwe and Uganda, respectively. PK non-adherence was 69% in the oral arms and 64% in the gel arm. For both oral and gel arms, modal adherence was “Good” per ACASI self-rating, and mean adherence
was ≥94% (FTFI-dose frequency), ≥93% (CPC), ≥89% (ACASI-dose frequency). Reporting ≤75% use in the past month by CPC, or no doses in the past week had good specificity (≥89%) at identifying PK non-adherence; however, <10% of the sample reported such use with any behavioral measure. None of the regression models had an AUC >0.65 for any single or combined behavioral measures, indicating slightly better prediction than a coin toss (0.5).

**Conclusions:** In this random sample of VOICE participants, PK thresholds based on route of administration indicated similarly low adherence for the oral and vaginal gel arms. None of the behavioral measures correctly predicted PK non-adherence. Accurate real-time, low-cost objective and/or biological measures that minimize opportunities for manipulation or respondent-bias are urgently needed to facilitate real-time adherence monitoring in PrEP trials.

### 153LB HIV Transmission Risk Through Condomless Sex If HIV+ Partner On Suppressive ART: PARTNER Study

**Alison Rodger**,1 Tina Bruun2, Valentina Cambiano3, Pietro Vernazza4, Vicente Estrada5, Jan Van Lunzen6, Simon Collins6, Anna Maria Geretti7, Andrew Phillips1, Jens Lundgren8, for the PARTNER Study Group

1Research Department of Infection & Population Health, University College London, London, United Kingdom, 2Copenhagen HIV Programme, University of Copenhagen, Copenhagen, Denmark, 3Infectious Diseases, Cantonal Hospital, St. Gallen, Switzerland, 4Department of Infectious Diseases, Hospital Clinico San Carlos, Madrid, Spain, 5Department of Infectious Diseases, University Medical Center, Hamburg, Germany, 6HIV i-Base, London, United Kingdom, 7Institute of Infection & Global Health, University of Liverpool, Liverpool, United Kingdom, 8Centre for Viral Diseases and the Copenhagen HIV Programme, University of Copenhagen, Copenhagen, Denmark

**Background:** The absolute risk of sexual HIV transmission on stable ART (HIV RNA viral load (VL) < 200 c/mL) from condomless sex is unknown. Current limited data are largely focusing on vaginal sex.

**Methodology:** The international, observational multi-centre PARTNER study prospectively follows serodifferent couples (heterosexual (HT) and MSM) who had condomless penile-anal or vaginal sex in the month prior to study entry, and where the HIV+ve partner is on ART. Every 6 months, each partner completes a sexual behaviour questionnaire and the negative partner tests for HIV. Eligibility of follow-up time in this transmission rate analysis required: continued condomless sex; not using PEP or PrEP; and latest VL <200 c/mL. For new diagnoses, phylogenetic analysis compared HIV-1 pol and env sequences by couple, after samples were anonymised. This planned analysis reports the rate of occurrence of linked transmissions.

**Results:** By 1st November 2013, 1110 couples were enrolled. Of 1151 couple-years of follow-up (CYFU), 894 were eligible (586 in HT and 308 in MSM). At baseline, the median duration on ART was 4.9 years (IQR: 1.9-11.4) and couples reported having condomless sex for a median 2 years (IQR: 0.5-6.3). Condomless sex with a different partner outside the partnership during follow-up was reported by 27% MSM and 2% HT HIV-negative partners. During follow-up, couples had condomless sex a median of 45 times/year (IQR: 16-90). Although some negative partners became HIV positive during FU, no phylogenetically linked transmissions occurred, giving a rate of within-couple HIV transmission during eligible couple-years of zero (95% CI: 0-0.40/100 CYFU)(Table). The upper limit of the 95% CI for the rate of transmission was 0.96/100 CYFU for condomless anal sex (HT and MSM) and 1.97/100 CYFU for condomless receptive anal sex with or without ejaculation (MSM).

**Conclusions:** The overall risk of HIV transmission (in the context of previous sex without transmission) through condomless anal or vaginal sex from HIV positive people on ART with plasma VL < 200 copies/mL is extremely low, but uncertainty over the risk remains, particularly over receptive anal sex. Additional follow-up in MSM is essential to provide more precise estimates for transmission risk given the current assumptions of safety in some communities.

Inhibition of Cul4A Neddylation Causes a Reversible Block To SAMHD1-Mediated Restriction of HIV-1

Henning Hofmann, Thomas D. Norton, Eric C. Logue, Megan L. Schultz, Sylvie B. Polsky, Nicole Sunseri, Nathaniel R. Landau

NYU School of Medicine, New York, NY, United States

Background: The deoxynucleoside triphosphohydrolase SAMHD1 restricts retroviral replication in myeloid cells. It is thought to work by depleting the pool of intracellular deoxynucleotide triphosphates but has also been reported to have exonuclease activity that could allow it to degrade the viral genomic RNA or viral reverse transcribed DNA. HIV-2 and SIVmac, but not HIV-1, encode Vpx, a virion-packaged accessory protein that counteracts SAMHD1 by inducing its degradation in the nucleus of a newly infected cell. To induce the degradation of SAMHD1, Vpx co-opts the culin4a-based E3 ubiquitin ligase, CRL4. E3 ubiquitin ligase complexes are regulated by neddylation, the covalent attachment of the small ubiquitin-like protein, Nedd8, to the cullin subunit. The small molecule MLN4924 prevents cullin neddylation. In this study MLN4924 was used to study the mechanism by which SAMHD1 restricts HIV-1.

Methodology: Monocyte derived dendritic cells (MDDC) were incubated with MLN4924 prior to infection with the Vpx-containing HIV-1.GFP reporter virus. The degradation of SAMHD1 was then determined by immunoblot analysis and infectivity was analyzed by flow cytometry. The effect of the neddylation inhibitor was also tested on a cell line that expressed the GFP-SAMHD1 fusion protein that contained only the Vpx-interacting domain of SAMHD1. The cell line allowed measurement of the kinetics and cellular requirements for Vpx-mediated degradation of SAMHD1.

Results: MLN4924 inhibited the neddylation of CRL4, blocking the Vpx-induced degradation of SAMHD1. Incubation of cells expressing the GFP-SAMHD1 fusion with Vpx-containing HIV-1 resulted in a rapid reduction in GFP fluorescence and the reduction was blocked by MLN4924. The neddylation inhibitor maintained SAMHD1-mediated restriction in cells that expressed SAMHD1 when infected with Vpx-containing HIV-1. In cells that did not express SAMHD1 the drug had no effect on infectivity. Removal of the drug several hours post-infection released the block. Similarly, Vpx-containing virus-like particles and deoxynucleosides added to the cells more than 24 h post-infection released the SAMHD1-mediated block.

Conclusions: The block to SAMHD1-mediated restriction of HIV-1 is reversible for several hours, arguing against an exonuclease mechanism and supporting dNTP pool depletion as the primary mechanism of restriction. Virus replication requires the function of various cullin-based E3 ubiquitin ligases. Thus, this class of small molecules may have antiviral activity and at least one is already approved for use in humans.

MX2, an Interferon-Induced Inhibitor of HIV-1 Infection

Melissa Kane1, Shalini S. Yadav1,2, Julia Bitzegeio1, Sebastia Kuttugay1, Trinity Zang1, Sam J. Wilson1,2, Daniel Blanco-Melo1, Masahiro Yamashita3, Theodora Hatziioannou3, Paul D. Bieniasz2,3

1The Rockefeller University, New York, NY, United States, 2Howard Hughes Medical Institute, New York, NY, United States, 3Aaron Diamond AIDS Research Center, New York, NY, United States

Background: HIV-1 replication can be inhibited by type I interferon (IFN), and the expression of a number of gene products with anti-HIV-1 activity is induced by type I IFN. However, none of the known antiretroviral proteins can account for the ability of type I IFN to inhibit early, preintegration phases of the HIV-1 replication cycle in human cells.

Methodology: Screens of interferon stimulated genes and comparison of gene expression profiles in cell lines that differ in their ability to restrict HIV-1 infection upon exposure to IFN-α revealed MX2 as a potential anti-HIV-1 protein. We examined the the ability of wild type MX2, and mutant forms of lacking GTPase activity, the nuclear localization signal, or leucine rich effector domain to inhibit HIV-1 infection in stably transduced cell lines.

Results: Ectopic expression of MX2 inhibited infection by HIV-1 and a variety of other primate lentiviruses, while knockdown of MX2 expression reduced the anti-viral effect of type I IFN. We found that the The GTPase activity of MX2 was dispensable for inhibition of infection. However, both the N-terminal nuclear localization and C-terminal leucine-rich effector domains were required. HIV-1 reverse transcription proceeded normally in MX2-expressing cells, but 2-LTR circular forms of HIV-1 DNA were less abundant, suggesting that MX2 inhibits HIV-1 nuclear import, or destabilizes nuclear HIV-1 DNA. Consistent with this notion, mutations in the HIV-1 capsid protein that are known, or suspected, to alter the nuclear import pathways used by HIV-1 conferred resistance to MX2, whereas preventing cell division increased MX2 potency. Finally, the anti-viral activity of MX2 did not appear to be species-specific, as MX2 proteins from a variety of Old and New World monkey species (rhesus macaque, African green monkey, Owl monkey, and squirrel monkey) were able to inhibit HIV-1 infection.
Conclusions: Our findings demonstrate that MX2 is an effector in the anti-HIV-1 activity of type I IFN, but is not solely responsible for the inhibitory action of IFN-α during the early steps of the HIV-1 replication cycle. The anti-viral activity of MX2 may involve the inhibition of HIV-1 nuclear import, and appears to be conserved among primate species.

BCA2/Rabring7 Targets HIV-1 Gag for Lysosomal Degradation in a Tetherin-Independent Manner
Ruth Serra-Moreno
Harvard Medical School, Southborough, MA, United States

Background: BCA2 (Breast Cancer-Associated gene 2, Rabring7) is an E3 ubiquitin ligase that was identified as a co-factor in the restriction imposed by tetherin on HIV-1, lacking antiviral activity in the absence of tetherin. Contrary to this model, we found that BCA2 also possesses tetherin-independent antiviral activity, which leads to a reduction in the cellular levels of Gag, and therefore, in the amount of virus particles released from cells.

Methodology: Virus release assays (p24 ELISA) were performed from tetherin-deficient cells transiently transfected with HIV proviral DNA and constructs coding for tetherin, BCA2, or BCA2 mutants. To explore if BCA2 promotes the degradation of Gag, similar assays were performed in the presence of proteasomal (ALLN, clasto-lactacystin-β-lactone) and lysosomal inhibitors (chloroquine, pepstatin, leupeptin, E64). To investigate if BCA2 promotes Gag ubiquitination, cells were engineered to express Gag and BCA2. The levels of Ub-Gag were determined by immunoprecipitation followed by western blotting, using an Ubiquitin-specific antibody. Next, Gag was tested for an interaction with BCA2 by co-immunoprecipitation. The role of endogenous BCA2 in virus release and replication was investigated by shRNA knockdowns. Finally, the effects of BCA2 on the subcellular distribution of Gag were evaluated by confocal microscopy.

Results: Expression of BCA2 in tetherin-deficient cells caused a ~3-fold decrease in virus release. Western blot analyses indicated that this corresponds to a defect in Gag expression, with no effects on the levels of other viral proteins. Our binding and ubiquitination assays showed that BCA2 interacts with Gag through the Matrix region, and that BCA2 promotes Gag ubiquitination. The addition of lysosomal inhibitors to BCA2-expressing cells significantly restored Gag levels and virus release. The targeted depletion of BCA2 resulted in a substantial increase in virus release (5-fold more) and virus replication (10-fold more). Finally, cellular imaging assays revealed that BCA2 induces drastic changes in the subcellular distribution of Gag, which is primarily present in endolysosomal compartments.

Conclusions: (1) BCA2 has tetherin-independent antiviral activity; (2) BCA2 promotes the ubiquitination and lysosomal degradation of HIV-1 Gag; and (3) the targeted depletion of BCA2 in tetherin-deficient cells increases virus release and replication, indicating that endogenous BCA2 possesses antiviral activity. These results indicate that BCA2 is an important antiviral factor that promotes the degradation of HIV-1 Gag, thereby, impairing virus assembly.

Crystal Structure of APOBEC3F Elucidates HIV-1 Vif Interaction and Dynamic Oligomerization
Markus-Frederik Bohn, Shivender M. D. Shandilya, Mohan Somasundaran, Celia A. Schiffer
Biochemistry, UMass Medical School, Worcester, MA, United States

Background: Human APOBEC3F is an anti-retroviral ssDNA cytosine deaminase, susceptible to proteasomal degradation mediated by the HIV-1 protein Vif. Elucidating regulation of APOBEC3F and susceptibility to Vif might lead to novel approaches in antiretroviral therapy.

Methodology: We determined the crystal structure of the HIV-1 Vif interacting catalytically active, C-terminal domain of human APOBEC3F and performed dynamic light scattering experiments to investigate the solution state of different APOBEC3F mutants.

Results: The catalytic domain of APOBEC3F shares structural motifs with APOBEC3C, APOBEC2 and the C-terminal domain of APOBEC3G. Residues previously identified as determinants of susceptibility to Vif-mediated degradation fit within a charged contiguous surface on APOBEC3F. Sequence motifs critical for Vif susceptibility and virion encapsidation are shown to be conserved across APOBEC3 family members and between APOBEC3F and Vif. Physiological APOBEC3F activity is dependent on a conversion from high molecular mass complexes of megadalton in size to a low molecular mass form of less than 100 kD. The single domain protein APOBEC3A does not undergo a similar conversion. We show the C-terminal domain of APOBEC3F being capable of forming complexes of high molecular mass in solution which are not observable for APOBEC3A. Interface residues identified from the crystal structure of APOBEC3F are the determinants of APOBEC3F complex formation.

Conclusions: The identification of potential oligomerization interfaces might help elucidate the anti-viral regulatory role of high molecular mass complexes of active APOBEC3 proteins and facilitate approaches utilizing modulation of APOBEC3 activity in novel antiretroviral strategies.

Crystal Structure of a TRIM Coiled-Coil: Implications for HIV-1 Capsid Recognition by TRIM5α
Jacint G. Sanchez1, Katarzyna Okreglicka1, Viswanathan Chandrasekaran1, Jordan M. Welker1, Wesley I. Sundquist2, Owen Pornillos1
1Molecular Physiology and Biological Physics, University of Virginia, Charlottesville, VA, United States, 2Biochemistry, University of Utah, Salt Lake City, UT, United States

Background: TRIM5α is a cytosolic pattern-recognition receptor that intercepts incoming capsids of retroviruses, including HIV-1. Capsid recognition results in species-specific restriction of viral replication and induction of an innate immune response. The prevailing model is that TRIM5α recognizes the HIV capsid through synergy of at least 3 biochemical activities: direct binding of capsid subunits by a B30.2/SPRY domain, TRIM5α dimerization, and higher-order assembly of the tripartite motif into a hexagonal lattice. A key point is that multiple B30.2 domains in the TRIM5α assembly are positioned to match the spacing of their repeating binding epitopes on the capsid surface, thereby vastly amplifying the avidity of capsid recognition. However, the molecular details of the above biochemical activities remain to be uncovered. The tripartite motif is a series of domains - RING, B-box, and coiled-coil - arranged in that order from the N-terminus. Here, we describe the structure of the coiled-coil, which mediates TRIM dimerization and is required for higher-
order TRIM5α assembly. Our studies reveal how TRIM5α dimerizes, how it positions the B30.2/SPRY domains to bind capsid subunits, and how TRIM5α dimers organize into hexagonal arrays to recognize the capsid lattice and restrict viral replication.

Methodology: Working under the framework that a comprehensive mechanistic model must address how the various TRIM domains are structurally coupled, we initially focused on the coiled-coil, because it specifies dimerization and defines the spatial relationships between the other domains. We used human TRIM25 as a model system since it lacks TRIM5's propensity for higher-order assembly and is therefore more tractable biochemically. We determined the crystal structure of the TRIM25 coiled-coil at 2.6 Å resolution. Based on this structure, we built and experimentally validated a homology model for the TRIM5α coiled-coil.

Results: Our analyses revealed that: 1) the TRIM coiled-coil is an elongated dimer of hairpin-shaped subunits; 2) the coiled-coil dimers form the edges of the TRIM5α hexagon, positioning two C-terminal B30.2 domains at the center of each edge and the N-terminal RING and B-box domains at the vertices; and 3) the "L2" linker between the coiled-coil and B30.2 is integrated with the tripartite motif and participates in dimer formation. We propose that the L2 linker of TRIM5α structurally couples the tripartite motif to its B30.2 domain, thereby orienting the two capsid-binding domains of one TRIM5α dimer on the same side and positioning them with a defined spacing relative to each other.

Conclusions: Our studies support a model wherein TRIM5α proteins recognize retroviral capsids by acting as "molecular rulers" that measure the spacing of the assembled capsid subunits.

50 Global Identification of the RNA Targets of HIV-1 Gag During Particle Genesis
Sebiba Kulluya1, Daniel Blanco-Melo2, Trinity Zang3, Paul D. Bieniasz1,2
1Aaron Diamond AIDS Research Center, New York, NY, United States, 2Rockefeller University & Howard Hughes Medical Institute, New York, NY, United States

Background: HIV-1 Gag protein selectively packages two copies of the viral genome, an event thought to be primarily mediated by interactions between the packaging signal (Ψ) on the viral genome and the nucleocapsid domain of Gag. However, the Ψ sequence is defined based only on genetic studies and limited in vitro binding data. To date, no assay has been able to demonstrate a direct and specific interaction between Ψ and Gag protein in a relevant context, i.e. in live cells and in virions. Importantly, deletion of Ψ does not completely abolish genome encapsidation, suggesting that packaging may be more complex than Ψ-Gag interaction, and other regions on the viral genome may contribute. Finally, Gag undergoes several changes in localization, multimerization state and is proteolytically processed during particle genesis, but it is completely unknown how these changes affect RNA-binding properties of Gag. Therefore, we set out to determine globally and at near-nucleotide resolution the RNA targets of Gag during various stages of virion genesis, in cells and in virus particles.

Methodology: To identify the RNA targets of Gag, we adapted a CLIP-seq (crosslinking-immunoprecipitation-sequencing) methodology, which combines immunoprecipitation of covalently crosslinked protein-RNA complexes with high-throughput sequencing. This method globally identifies the RNA molecules associated with an RNA-binding protein of interest in biological settings and provides near-nucleotide-resolution information about the protein-RNA interaction sites.

Results: In addition to determining precisely where within Ψ Gag is bound, we identified several novel sites on the viral genome that are specifically bound by Gag in the cytosol of cells. Mutation of these sites delayed virus replication and we are currently investigating whether this is due to defects in genome packaging. Experiments performed on fractionated cells and in virions indicated that there are major changes in RNA binding specificity during particle morphogenesis: in contrast to cytosolic Gag, Gag associated with the plasma membrane and in virions binds to numerous other regions on, but does not uniformly coat, the viral genomic RNA. We have also globally identified several cellular RNA molecules, such as 7SL RNA, that are specifically bound by Gag in the cytosol and encapsidated into virus particles.

Conclusions: Our studies indicate that Gag selects viral genome for packaging by binding to a few distinct regions on the viral genome and that association with the plasma membrane and particle formation induces significant changes in the RNA-binding properties of Gag. These studies provide the first dynamic, quantitative and high-resolution picture of viral/cellular RNA interactions with Gag in relevant biological contexts.

51 Gorillas Transmitted SIV To Humans: Identification of HIV-1 Group P and O Ancestors
Mirela D’arc1, Ahidjo Ayoubua, Amandine Esteban6, Avelin Aghokeng1,2, Sabrina Locatelli3, Lucie Etienne2, Beatrice Hahn4, Eric Delaporte2, Eitel Mpoudi Ngole5, Martine Peters6
1Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, 2UMI 233, IRD and University of Montpellier 1, Montpellier, France, 3Projet PRESICA and IMPM/CREMER, Yaoundé, Cameroon, 4University of Pennsylvania, Philadelphia, PA, United States, 5Projet PRESICA and IMPM CREME, Yaoundé, Cameroon

Background: Western lowland gorillas (G. g. gorilla) are infected with a simian immunodeficiency virus, SIVgor, that is related to HIV-1 groups O and P. Partial SIVgor sequences suggested that gorillas from southwest Cameroon are infected with the ancestor of HIV-1 P, but the origin of HIV-1 O remained unclear. In order to confirm whether gorillas are the reservoir of HIV-1 P and to elucidate the origin of HIV-1 O, we studied more in detail SIVgor in wild gorillas from Cameroon and characterized full-length genomes of new SIVgor strains.

Methodology: Between 09/2009 and 06/2013, we collected 1559 fecal samples from wild gorilla populations at 14 different sites in southern Cameroon. All samples were preserved in RNALater and then tested for presence of HIV cross-reactive antibodies. We extracted nucleic acids from reactive samples and performed RT-PCR using SIVcpz/SIVgor/HIV-1 consensus and specific primers. We sequenced the full-length genome of two new SIVgor strains. The species and enumeration of individuals were obtained by mitochondrial DNA and microsatellite analyses. We used PhyML for phylogenetic analyses.

Results: SIVgor antibodies were identified in 69/1559 samples from 4/14 sites. Partial viral sequence analyses showed a high genetic diversity, with strains closely related to HIV-1 O and P. The full-length genome sequence of the new SIVgorBP-ID01 strain (9029 bp), from southwest Cameroon, was
most closely related to HIV-1 P across the entire genome. At least two gorilla populations were infected with this SIVgor variant at high rates (54%). Analyses of SIVgorBQ-ID01 (full-length, 9236 bp), from a gorilla from southwest Cameroon, revealed a recombinant SIVgor strain with 6914 bp of the genome most closely related to HIV-1 O and fragments in pol (470 bp) and env (1850 bp) that were most closely related to other SIVgor strains. To calculate the genetic distances, a modified alignment was completed, and breakpoint information was used to extract the non-group O related regions of the SIVgorBQ-ID01 from the genome alignment. Genetic distances between SIVgorBQ-ID01 / HIV-1 O (0.167) and SIVgorBP-ID01 / HIV-1 P (0.124) were smaller than between SIVcpz and their HIV-1 counterparts, groups M (0.260) or N (0.158).

Conclusions: Gorilla populations from southwest Cameroon are the direct source of HIV-1 P and we show for the first time that SIV sequences closely related to HIV-1 O circulate also in wild gorilla populations. Further studies are needed to identify more in detail the sources of HIV-1 O. Although SIV infection is less widespread in gorillas than in chimpanzees, SIVgor was most likely transmitted to humans on two occasions. These new findings show that we are closer to resolve the origins of all HIV-1 groups and that two ape species are involved in the origin of HIV-1 in humans.

52LB A Gorilla Reservoir for Human T-lymphotropic Virus Type 4 (HTLV-4)
Matthew LeBreton¹,², William M. Switzer³, Cyrille F. Djoko², Amethyst Gillis², Hongwei Jia³, Walid Heneine³, Anupama Shankar¹, HaoQiang Zheng³, Bradley S. Schneider¹, Nathan D. Wolfe¹,⁴
¹Metabiota, San Francisco, CA, United States, ²Global Viral Cameroon, Yaoundé, Cameroon, ³CDC, Atlanta, GA, United States, ⁴Global Viral, San Francisco, CA, United States

Background: While the primate origins of human retroviruses have been identified by detailed epidemiologic and phylogenetic analyses of isolates from both humans and nonhuman primates (NHPs), of the seven known species of human retroviruses, one, HTLV-4, lacks a known animal reservoir. HTLV-4 was discovered in 2005 in a 48-yr-old male hunter from rural Cameroon who reported hunting monkeys, chimpanzees, gorillas, and other animals and currently represents the only known primate (human or simian) virus in this lineage.

Methodology: 1,107 individual captive and wild NHPs from Cameroon consisting of 21 species were screened for evidence of simian T-cell lymphotropic virus type 4 (STLV-4) infection, the simian origin of HTLV-4, using a real-time PCR assay specific for the detection of HTLV-4-like pol sequences. pol, env, tax and full genome sequences were obtained by nested PCR from positive samples. Phylogenetic analyses to demonstrate the genetic relatedness of STLV-4 and HTLV-4 and to estimate the possible date of STLV-4 entry into humans using detailed Bayesian phylogenetic analyses were performed.

Results: Of the 1,107 individuals of 21 species tested, samples from only three wild and three captive gorillas were positive. Partial PTLV-4 (primate-T-cell lymphotropic virus type 4) pol, env and tax sequences were detected for the six gorilla samples and all showed at least 99% nucleotide identity to HTLV-4 (1863LE) and to each other. These results were confirmed by phylogenetic analysis of tax and pol sequences which showed a clustering of all STLV-4 sequences with those from HTLV-4. One gorilla was dually infected with PTLV-1. TMRCA estimates for the PTLV-4 ancestor were 3,300 - 8,400 years suggesting a relatively recent introduction of STLV-4 into humans.

Conclusions: These findings indicate that STLV-4 is endemic to gorillas, and that HTLV-4 recently emerged from a gorilla reservoir, likely through the hunting and butchering of wild gorillas. Our findings shed further light on the importance of gorillas as keystone reservoirs for the evolution and emergence of human infectious diseases and provide a clear course for preventing HTLV-4 emergence through management of contact with gorillas, the development of improved assays for HTLV-4/STLV-4 detection, and the monitoring of STLV-4 among gorillas and for HTLV-4 zoonosis among individuals exposed to gorilla populations.
T Memory Stem Cells: The Stem Cell Reservoir for HIV?
Mathias Lichterfeld
Massachusetts General Hospital, Boston, MA, United States

Background: Current antiretroviral combination therapy is extremely effective in suppressing HIV-1 viremia, but replication-competent HIV-1 can persist for extremely long-periods of time despite effective treatment with HAART. Defining the cell types that serve as a reservoir for long-term persistence of HIV-1 is critical for designing interventions that may at one point lead to HIV-1 eradication and cure. Stem cells represent the most long-lasting human cells and are maintained by specific molecular programs that induce self-renewal, homeostatic proliferation and resistance against apoptotic cell death. Tissue-specific stem cells, in particular hematopoietic stem cells, have been proposed as long-term reservoirs for HIV-1, but their role for HIV-1 persistence remains controversial. A number of recent observations indicate that molecular stem cell programs are not exclusively active in classical organ-specific stem cells, but also govern developmental programs of cellular immune memory. In fact, recent data suggest that the process of memory T cell development originates from an exquisitely rare population of T cells with stem cell-like properties. These cells, termed T memory stem cells, likely represent the earliest and most immature developmental stage of memory T cells and have recently been described in humans, mice and non-human primates. Functionally, T memory stem cells exceed the proliferative capacity of all known alternative memory T cell subsets, and can differentiate into large numbers of mature effector T cells, while maintaining their own pool size through homeostatic self-renewal. Due to these characteristics, CD4 T memory stem cells may represent a preferred cellular niche for HIV-1 persistence during suppressive antiretroviral therapy.

Conclusions: Our data suggest that CD4 T memory stem cells are susceptible to HIV-1, and harbor high levels of HIV-1 DNA in HIV-1 infected patients treated with suppressive HAART. In addition, we show that HIV-1 DNA levels in these cells remain stable for many of antiretroviral therapy, and that the relative contribution of these cells to the total viral reservoir increases over time. As such, HIV-1 infected CD4 T memory stem cells may represent a stem-cell like reservoir for HIV-1 that has a similar function for maintaining HIV-1 persistence as cancer stem cells have for perpetuating certain oncologic diseases. The increasing understanding of how stem cell-like properties of cellular immune memory support HIV-1 persistence despite HAART may be translatable into improved clinical strategies for inducing HIV-1 eradication.

Inflammation as an Obstacle for Remission: Lessons Learned From Non-Human Primate Models
Michaela Müller-Trutwin
Institut Pasteur, Paris, France

Background: Chronic immune activation (IA) during HIV-1 infection persists even in patients with controlled viremia. This residual inflammation might fuel viral replication by creating new target cells and thus could represent an additional obstacle for cure. Early treatment likely has a favourable impact on the reduction of viral reservoirs, and eventually on the inflammatory set point. Non-human primate models allow analyzing the early events after viral infection, exploring the nature of the viral reservoirs in tissues and searching the factors, which initiate chronic immune activation. Several non-human primate models for virological or inflammatory control exist. We have shown previously that natural hosts of SIV (African green monkeys, AGM) are capable to efficiently resolve inflammation by the end of acute SIVagm infection. Based on this observation in AGMs, we had analyzed if the early level of inflammation during HIV-1 infection would predict the disease progression rate. We reported elevated plasma CXCL10/IP-10 levels during primary HIV-1 infection being more robust predictors of rapid progression toward AIDS than viral RNA and CD4 counts.

Conclusions: Here, we show that during acute HIV-1 infection, plasma IP-10 level was a better predictor of rapid disease progression than viral DNA. Moreover, we evaluated whether the plasma levels of IP-10 already before SIV infection and before HIV-1 infection (Amsterdam Cohort Studies) have an impact on the outcome of infection. We quantified the expression of an endogenous antagonist of IP-10 and observed that its frequency is decreased during primary HIV-1 infection in those patients who rapidly loose their CD4+ T cells (ANRS PRIMO Cohort No6). Finally, we investigated the source of IP-10 in Humans and in non-human primates (rhesus macaques and African green monkeys), probing blood and relevant tissues, notably the gut (in the simian models). The IP-10 expression in intestinal CD4+ cells was associated with IP-10 plasma levels, suggesting that plasma levels can reflect the levels of IP-10 production in the gut and/or that these gut cells represent the major source of systemic IP-10. These studies are in favor of IP-10 as a robust early biomarker for inflammation and of efforts combining viral suppressive therapies with anti-inflammatory strategies.

Humanized Mouse Models for Studies On HIV Latency, Reservoirs, and Eradication Strategies
J. Victor Garcia-Martinez
University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Background: Humanized mice represent a relatively recent tool in the growing armamentarium of animal models for the in vivo study of HIV and other human hematotropic viruses. These models can be created by transplanting human hematopoietic cells into immunodeficient mice. However, the choice of mouse strain used can have dramatic effects on the reconstitution of key immune organs like the gut. Another important, issue that affects reconstitution and outcomes is the co-implantation of human thymus, used in the bone marrow/liver/thymus (or BLT) model, which can result in bona fide education of human T cells in the context of HLA. Highly relevant to in vivo studies of HIV persistency has been the development and implementation of adequate drug regimens that can suppress peripheral blood viremia. This has been achieved in mouse models using the same antiretrovirals used in humans. Also critical to these efforts, has been the establishment of sensitive and reproducible assays for latency in human T cells obtained from these mice. This has been recently demonstrated in mouse models using the same methodology used to quantitate the number of latently infected cells present in the peripheral blood of humans. Based on this information, BLT humanized mice have more recently been used to establish the systemic distribution of latently infected cells in vivo and to evaluate novel approaches to destroy residual HIV+ cells in tissues. Specifically, we used BLT humanized mice to evaluate the efficacy of envelope targeted immunotoxins to kill HIV infected cells in the tissues of ART suppressed mice.
Conclusions: Our results demonstrate that this approach can be highly effective at killing residual HIV infected cells in vivo. In summary, humanized BLT mice serve as a flexible and accessible platform for the in vivo evaluation of novel approaches for the study of HIV latency, reservoirs and eradication strategies.

Session S2 Symposium
4:00 PM – 6:00 PM Ballroom A
HCV and Beyond

57 HEV: State of the Art
Kenneth E. Sherman
University of Cincinnati College of Medicine, Cincinnati, OH, United States

Background: The hepatitis E virus (HEV) is a small, fecal-oral transmitted RNA virus with a worldwide distribution. There are multiple genotypes which are associated with both host and geographic specificity. In resource-limited regions of the world, large epidemics of acute hepatitis associated with HEV are common during periods of flooding, or with poor sanitation in refugee camps and during military conflict. The endemic nature of the infection in Western countries has not been widely recognized. It seems to be highly associated with exposure to swine and swine products infected with HEV genotype 3. Misclassification of acute hepatitis as drug injury, which was actually attributable to acute HEV infection has been described. Testing for HEV remains problematic. Recent data suggests that HEV is highly prevalent in those with HCV, though the transmission epidemiology of this finding is uncertain. Furthermore, in immunosuppressed hosts, including those with HIV infection, as well as transplant recipients the virus is capable of establishing a chronic infection which can be associated with progressive hepatic fibrosis. HEV viral clearance with ribavirin, interferon, or withdrawal of immunosuppression has been described.

Conclusions: HEV is increasingly recognized as a cause of both acute and chronic liver injury in the United States and other Western countries. Chronic infection can lead to progressive liver injury and cirrhosis in immunosuppressed hosts.

58 HBV Eradication: Similarities To and Differences From HIV
Shyam Kottili
National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Background: Chronic hepatitis B virus (HBV) infection is a major public health concern affecting over 500 million people worldwide. HBV is a partially double stranded DNA virus that preferentially infects hepatocytes and causes acute hepatitis. While this acute hepatitis resolves in most patients, a subset of patients progress to chronic hepatitis with development of liver fibrosis. HBV shares several features with HIV that includes similar routes of transmission, development of chronic disease, and use of a reverse transcriptase enzyme to integrate in to the host genome. The latter feature is associated with the difficulties involved in eradicating HBV in chronically infected patients. Current treatment options for HBV include pegylated interferon alfa and nucleotide based therapy. Suppression of HBV replication is achieved in most treated patients, however, similar to HIV infection, discontinuation of therapy is associated with relapse of HBV viremia. Unlike HIV infection, both innate and adaptive immune responses have been associated with resolution of acute HBV infection and development of protective immunity in most adult patients exposed to HBV resulting in resolution of acute HBV infection. However, strategies to replicate this protective immunity in human subjects, which would enable them to stop antiviral therapy, have not yet been successful. Major reasons for our inability to cure HBV in chronically infected subjects include both viral and host factors. Viral factors such as a highly error prone replication system, presence of pre-core mutants, immune escape mutants and host factors that result in a lack of development of adaptive immune responses against HBV underscore the difficulties in our ability to boost HBV specific immunity in vivo. Recently, several strategies to eradicate HBV have been adopted that target the virus (potent directly acting antiviral agents, agents that target release of HBsAg), target innate immune system (toll-like receptor agonists), enhance antiviral immunity (therapeutic vaccinations) and target immunoregulatory mechanisms (PD-1, Tim-3). These approaches are promising, however, the safety profile of targeting key immunoregulatory mechanisms that may be vital for maintenance of physiological homeostasis of host immunity may need to be carefully evaluated.

Conclusions: A combination of targeting the virus and boosting host immunity may be the ideal approach to eradicate HBV. The safety of such an approach chronic hepatitis B patients needs to be evaluated.

59 Humoral Immunity and the Innate Response To HCV
Andrea L. Cox
The Johns Hopkins University School of Medicine, Baltimore, MD, United States

Background: Hepatitis C virus (HCV) infection is a blood born disease with global distribution that affects almost 3% of the world’s population and 25% of those with HIV in the United States. In the United States and many other countries, HCV remains the leading cause of liver failure requiring transplantation and of hepatocellular carcinoma. Continuing advances in therapeutic regimens are promising for effecting cures of HCV and may reduce transmission. However, access to therapy is limited for many of those infected given its costs and the fact that HCV often goes undiagnosed. In addition, therapy for HCV does not provide immunity against subsequent reinfection or fully reverse damage already done to the liver, much of which is thought to be immune mediated. Due to the silent nature of most chronic infections, diagnosis of HCV infection before significant damage is done to the liver can be challenging. This is particularly true of those with HIV infection, in whom liver diseases progresses more quickly. Thus, prevention of chronic infection through prophylactic vaccination and development of therapies to reverse damage in those with liver disease remain a priority. Understanding the immune response to HCV is important for development of both.
**Conclusions:** The host-virus interaction during the earliest stages of HCV infection influences the developing immune response and, ultimately, the outcome of infection. Recently, novel mechanisms of viral recognition utilizing a family of cytosolic pattern-recognition-receptors called the nucleotide-binding oligomerization domain (NOD)-like receptors have been reported. Engagement of NOD receptors activates the inflammasome-complex leading to production of the pro-inflammatory, inflammasome-associated cytokines interleukin (IL)-18 and IL-1β. These cytokines not only amplify the innate antiviral immune response and skew developing adaptive immune responses, but high levels are associated with cardiovascular disease and metabolic syndromes. In following subjects at high risk of HCV infection longitudinally from pre-infection through clinical outcome, we determined that IL-18 was the earliest and the most reliable host response to acute HCV infection measured in blood. IL-18 remains elevated in chronic infection, although at lower levels than in the acute phase of infection. HIV infection is also associated with high IL-18 levels. This talk will present a summary of recent data from multiple groups on the mechanisms by which HIV and HCV induce activation of the inflammasome-complex, modulation of this response in chronic infection, and the effect of the humoral response on this innate sensing. Better understanding of this innate response may increase understanding of protective immunity and pathogenesis.

60 **Interferon Alfa-Free Treatment of HCV**

Jean-Michel Pawlotsky
Henri Mondor Hospital, University of Paris-Est, Créteil, France

**Background:** Hepatitis C therapy is living its revolution. Several new anti-hepatitis C virus (HCV) drugs have reached the market and many others, including direct-acting antivirals (DAAs) and host-targeted agents (HTAs), are at the late clinical developmental stage. Several all-oral, interferon-free drug combination strategies are being developed, including nucleotide-based strategies, nucleoside-free strategies based on 3 DAAs with a low barrier to resistance, nucleoside-free strategies based on 2 DAAs including at least one second-generation drug with a higher barrier to resistance. Infection cure rates over 90% can be expected with these new therapies.

**Conclusions:** A number of unanswered questions and challenges however remain that will need to be addressed, including treatment of special populations, the role of ribavirin in interferon-free regimens, the role of HCV resistance in HCV treatment failures, strategic choices and cost issues, as well as screening and broad access to care in resource-constrained areas.

---

**Notes From the Field: Implementing PrEP in Resource Constrained Settings**

Nelly R. Mugo
Kenya Medical Research Institute, Nairobi, Kenya

**Introduction:** Unequivocal evidence from landmark clinical trials has demonstrated that oral tenofovir disoproxil fumarate-based Pre-Exposure Prophylaxis (PrEP) is a highly effective biomedical intervention for preventing acquisition of HIV-1 infection. For the first time we have a much sought HIV prevention tool for vulnerable HIV-uninfected individuals without requiring negotiation of safe sex with partners. We currently have a robust toolbox of evidence-based biomedical and behavioural HIV prevention strategies that can be used in combination to effectively combat the HIV/AIDS epidemic.

However, clinical trial efficacy is only the first step towards public health effectiveness. For high impact public health implementation, we require a delivery package that is both acceptable and accessible to the populations that most need it.

The use of antiretroviral medications both as treatment and prophylaxis in combination with other interventions has shifted the goals of prevention of mother to child HIV transmission towards elimination; similarly, current evidence of PrEP and treatment as prevention in combination with each other and other preventative strategies can shift the goals of prevention of sexual HIV transmission towards zero new infections.
From clinical trial efficacy to public health effectiveness, PrEP requires innovative implementation strategies and unrelenting demand creation. In the absence of these efforts a highly effective and needed HIV prevention intervention will join the pile of effective and underutilized public health interventions as the pool of newly infected individuals continues to rise.

This presentation will discuss current on going activities in resource restrained settings that will inform both science and policy makers on PrEP implementation such as the current on-going ‘demonstration projects’ and options for successful PrEP delivery.

Conclusion: PrEP implementation is not only possible, but it is required in resource-constrained settings.

63 A Community Perspective On PrEP
Christopher Balthazar and London Dorris
Stroger Hospital of Cook County, Chicago, IL, United States

Background: Following the success of several clinical pre-exposure prophylaxis (PrEP) trials and the approval of FTC/TDF for the prevention of HIV, attention has shifted to the interest and uptake of PrEP as well as the best practices for PrEP implementation. In the United States, young men who have sex with men (YMSM), particularly racial minority YMSM, are an anticipated target population for PrEP interventions. Thus, a better understanding of community knowledge, interest, and attitudes about PrEP is important. The speakers bring extensive experience, both professional and personal, with community outreach and education around PrEP, recruitment and retention across multiple PrEP trials focused on YMSM (ATN 082, ATN 110/113, and iPrEx OLE), and adherence to daily PrEP.

Conclusions: Extensive efforts to engage with and educate adolescent and young adult MSM around PrEP have revealed a dearth of knowledge in community and school settings about this new HIV prevention approach. Within groups that have basic information about PrEP, misinformation is common and misconceptions have allowed PrEP use to quickly become stigmatized. For those who are taking PrEP, daily adherence can be difficult and integrating PrEP into sexual relationships can be challenging. However, for YMSM who are vulnerable to HIV infection, PrEP is a feasible and highly acceptable prevention intervention that can make a difference in their lives.

64 Choosing Populations for Maximal Impact
David V. Glidden
University of California San Francisco, San Francisco, CA, United States

Background: Oral emtricitabine/tenofovir (FTC/TDF)-based pre-exposure prophylaxis (PrEP) has been shown to prevent acquisition of HIV. PrEP is a promising, yet resource-intensive prevention strategy with high drug and monitoring costs. Providers and policy makers need evidence-based guidance to make decisions on prioritizing populations for PrEP. This talk will discuss development of optimal strategies for identifying subgroups for which PrEP will have maximum impact.

Conclusions: The efficient prioritization for subgroups tracks with the effectiveness of PrEP as measured by the absolute (rather than relative) difference in HIV incidence rates. Populations for which this difference is maximized have a lower number of individuals needed to treat (NNT) per infection prevented. Underlying HIV incidence and relative efficacy (and hence adherence) determine the absolute change in HIV rates due to PrEP. Hence, lower adherence in some settings may be offset by higher underlying HIV incidence and need not preclude the efficient delivery of PrEP. The population impact of PrEP prioritization strategies will be largely determined by the concentration of HIV incidence within that subpopulation, summarized by the population attributable fraction. Additional considerations for deployment include cost, resistance, toxicity and indirect effects on HIV by interrupting HIV transmission networks. We will illustrate these considerations by combining results of published modeling studies with results from the iPrEx trial (Grant et al, 2010) - a randomized study of daily FTC/TDF based PrEP in men who have sex with men.

65 B-Cell Responses To HIV Infection: Challenges and Opportunities
Susan L. Moir, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Background: B cells and the antibodies they secrete play a critical role in the prevention of and recovery from most infectious diseases. HIV remains an exception, both in terms of the inability of the antibody response to control the virus once an individual is infected and the difficulty in developing an antibody-based vaccine to prevent HIV infection. Of note, potent and broadly neutralizing antibodies against HIV can be elicited in 20 percent of untreated infected individuals and occur to varying degrees only after several years of infection. Paradoxically, the virus itself likely contributes to a broadening of the antibody response as it escapes neutralization by sequential mutations, thus explaining at least in part why a neutralizing antibody response provides little benefit to the infected individual. This presentation reviews how B cells that recognize T-cell dependent antigens, such as HIV, are induced in secondary lymphoid tissues and migrate to interact with CD4+ T follicular helper cells. These interactions lead to the formation of germinal centers that generate memory B cells and plasma cells, the latter of which migrate to the bone marrow to become long-lived sources of antibodies that ultimately circulate in the blood. Germinal center and memory B cells, as well as plasma cells, are perturbed in HIV disease, especially in individuals who do not control HIV viremia either naturally or as a result of antiretroviral therapy.
Conclusions: This presentation reviews the virologic and immunologic factors that likely contribute to the ineffectiveness of the early antibody response against HIV and those factors during the chronic phase of infection that likely exacerbate the inadequacy of the HIV-specific antibody response. Finally, recent advances that are providing new opportunities to improve the quantity and quality of HIV-specific antibody responses are discussed, as well as consideration for how passive immunization with such antibodies could be used to treat infected individuals.

Session PL4 Plenary
9:00 AM – 9:30 AM Auditorium

66 NeuroHIV in 2014: Beyond Dementia
Serena S. Spudich, Yale University, New Haven, CT, United States

Background: The fact that HIV infection directly impacts the central nervous system (CNS) has been recognized since very early in the global HIV epidemic. However, the emergence of widespread combination antiretroviral therapy (cART) use has dramatically altered the clinical character of neurologic disease observed in HIV, has led to new challenges related to optimization of CNS treatment, and raised a host of questions related to the role of the CNS as a potential barrier to HIV eradication and cure. This presentation will review key issues in this new landscape of clinical and scientific issues facing HIV-infected persons, providers, and investigators in the current era. Potential mechanisms of HIV-related CNS dysfunction observed in patients treated with cART include persistent CNS infection, ongoing immune activation, effect of comorbidities and risk factors including vascular disease, aging, and genetics, antiretroviral drug exposure in the CNS associated with either toxicity or inadequate tissue distribution, and neurologic injury accrued prior to initiation of antiretroviral treatment. Related to issues of persistent clinical CNS abnormality in the face of cART, an unexplored frontier of research has emerged due to isolated reports of successful HIV ‘cure’ in the systemic field: whether the CNS may provide a reservoir for infection which may be a significant impediment to efforts to eradicate HIV. The pathobiology of this putative reservoir is under active investigation, including studies on the timing of establishment of CNS infection, the potential cells and tissues harboring HIV in the CNS, evidence of independent evolution of HIV in the CNS, and the possibility of autonomous CNS sources of HIV replication in the setting of suppressive therapy.

Conclusions: Potent antiretroviral treatment for HIV has changed the spectrum of issues and questions related to HIV’s effects on the nervous system. Although cART treatment can almost always prevent or ameliorate the most severe form of HIV-associated dementia, numerous clinical and laboratory biomarkers suggest that the CNS is not always normal in cART-treated HIV infected individuals. Whether this persistent perturbation of the CNS has deleterious effects on the brain is uncertain; whether it in part reflects a reservoir for HIV within cells of CNS in the setting of apparently successful cART is an essential question of relevance to both treatment and cure strategies.

Session 0-5 Oral Abstracts
10:00 AM – 12:15 PM Room 304

Critical Issues in MTCT: Maternal Health and HIV Treatment in Children

67 A 15-Year Review of Maternal Deaths in a Background of Changing HIV Management Guidelines
Coceka N. Mnyani1, 2, Eckhart Buchmann2, Karlyn Frank1, Helen Struthers1, James McIntyre1
1Anova Health Institute, Johannesburg, South Africa, 2University of the Witwatersrand, Johannesburg, South Africa

Background: While there has been a global decline in maternal deaths, South Africa has seen a reversal in gains with an increase in the maternal mortality ratio in the past decade. Published data up to 2010 indicate that HIV-related infections remain the leading cause of maternal deaths in South Africa. The data do not reflect the impact of increased antiretroviral therapy (ART) coverage, and increase in CD4 threshold for pregnant women to 350 cells/mm³, since 2010.

Methodology: We assessed trends in maternal deaths over a 15-year period, 1997-2012, in a district referral hospital in Johannesburg, South Africa. The hospital has approximately 22,000 deliveries per annum, with about a third of pregnant women HIV-infected. It is part of a relatively well-functioning prevention of mother-to-child transmission (PMTCT) programme, where transmission rates have decreased to between 2% and 3% in the past decade. Time trends were analysed by comparing the number of maternal deaths; patterns in HIV-related deaths; and diagnosis and management of HIV disease in pregnant women, over four time periods. The periods coincide with major guideline changes in South Africa - Table 1.

Results: During the 15-year period, there were 590 maternal deaths in the hospital. Overall, HIV-related infections were the leading cause of maternal mortality, accounting for 37.8% of all deaths, followed by hypertension (17.5%) and obstetric haemorrhage (13.4%). Of the women who died, 20.5% had not accessed antenatal care, while 11.9% had no documented records of antenatal care. The majority of deaths occurred postpartum - 470/590 (79.7%), and HIV-related deaths increased between 2003 and 2008, and have remained stable around 40%. Out of a total of 284 HIV-infected women who died, 66 (23.2%) had documented initiation of antiretrovirals (ARVs). Of those that had a CD4 count done, 74.6% had a ≤ 200 cells/mm³.

Conclusions: In this review up to the end of 2012, HIV-related infections remained the leading cause of maternal deaths, despite the availability of efficacious ARVs. While HIV diagnosis during pregnancy improved, the majority of HIV-infected women who died were ART-eligible, and died without being started on ART. These findings are similar to national reports prior to the widespread availability of ART. In South Africa, gains made in PMTCT are not reflected in maternal mortality rates - targeted antenatal and postpartum interventions are needed if we are to decrease HIV-related maternal deaths.
Oral Abstracts

Abstract Listing

68 Incidence and Cofactors of Acute HIV During Pregnancy and Postpartum
John Kinuthia1, Alison Drake2, Daniel Matemo1, Barbra Richardson3, R. Scott McClelland4, Grace John-Stewart5
1Obstetrics and Gynaecology, University of Nairobi, Nairobi, Kenya, 2Global Health, University of Washington, Seattle, WA, United States, 3Biostatistics, University of Washington, Seattle, WA, United States, 4Medicine, Global Health, Epidemiology, University of Washington, Seattle, WA, United States, 5Global Health, Epidemiology, Medicine, Pediatrics, University of Washington, Seattle, WA, United States

Background: Tremendous progress has been made in identifying and treating women with HIV within prevention of mother-to-child HIV transmission (PMTCT) programs. However, PMTCT focuses predominantly on women with chronic HIV infection. Women who are HIV seronegative at antenatal HIV test may be reassured and fail to recognize continued risk for HIV acquisition. We evaluated rates and correlates of acute HIV infection among pregnant and postpartum women in Western Kenya.

Methodology: At two District Hospitals in Western Kenya, pregnant women seeking antenatal care were enrolled if they were HIV negative (by two rapid HIV tests), either at that visit or within the last three months. Consenting mothers completed a questionnaire that assessed sociodemographic characteristics and sexual behavior. Blood was obtained for nucleic acid amplification tests (NAATs) and genital swabs were collected for detection of sexually transmitted infections (STIs) at baseline and serially during 9 month postpartum follow-up.

Results: Between May 2011 and June 2013, 1305 women were enrolled. Median age was 22 years (interquartile range (IQR) 19-26), 1022 (78.3%) were married for a median duration of 7 (IQR 2-17) years and 712 (54.6%) had a positive NAAT at enrollment and 13 (4.7%) became infected during follow-up, either later in pregnancy (2) or postpartum (11). Six (29%) women with acute HIV infection had symptoms of primary HIV infection. During 1071 person-years of follow-up, estimated HIV incidence was 2.63/100 person-yrs (95% CI: 0.65-4.82). Shorter duration of marriage (OR=1.15, 95%CI: 1.01-1.32), history of STIs (OR=3.84, 95% CI: 1.4-10.57) and infection with syphilis (OR=9.95, 95% CI: 1.98-46.02) or bacterial vaginosis at enrollment (OR=2.88, 95% CI: 1.28-6.5) were associated with acute HIV infection. Maternal age, marital status, education level and age difference from partner did not differ between women with or without acute HIV infection.

Conclusions: Among pregnant/postpartum women in a high HIV seroprevalence region, risk of HIV incident infection was high and comparable to discordant couples or sex worker cohorts. Almost half of acute HIV infections were detected during pregnancy, suggesting value of repeat HIV testing at delivery. Screening and treatment for STIs, including bacterial vaginosis and syphilis may be useful for HIV prevention, particularly among women with history of STI in shorter duration partnerships. Other HIV preventive options (such as PrEP or partner treatment) should be assessed in this population.

69 Efficacy and Safety of LPV/r Versus EFV in HIV+ Pregnant and Breast-Feeding Ugandan Women
Deborah Cohan1, Paul Natureeba2, Albert Plenty3, Flavia Luwedde Julia Mwesigwa4, Veronica Ades4, Edwin Charlebois2, Tamara Clark Bridget Nzububara2, Moses Kamya5, Pius Okong5, Diane Havlin6
1OBGYN, University of California San Francisco, San Francisco, CA, United States, 2Infectious Diseases Research Collaboration, Kampala, Uganda, 3Medicine, University of California San Francisco, San Francisco, CA, United States, 4OBGYN, New York University, New York, NY, United States, 5Medicine, Makerere University, Kampala, Uganda, 6OBGYN, Makerere University, Kampala, Uganda

Background: 2013 WHO ART guidelines recommend EFV-based combination ART (cART) for all pregnant women, though there are limited data on maternal/infant outcomes and alternative ART regimens. We report maternal/infant outcomes of a randomized trial comparing LPV/r to EFV-based cART in rural Uganda.

Methodology: PROMOTE was an open label trial (NCT00993031) enrolling HIV+ cART-naïve pregnant women between 12-28 weeks gestation. Women received AZT/3TC and either LPV/r or EFV at enrollment through 1 year of breastfeeding. LPV/r increased to 600/150 twice daily at 30 weeks. We compared virologic, immunologic and safety outcomes between the 2 arms. All women received cotrimoxazole and infants received ART prophylaxis per 2013 WHO ART guidelines.

Results: 389 women enrolled - mean age was 29, median pre-ART CD4 count was 370 and mean pre-ART viral load was 61,611 c/mL. Compared to LPV/r, women on EFV were significantly more likely to achieve viral suppression (<400 copies/mL) by delivery (85.7% [LPV/r] vs. 97.6% [EFV], p < .0001) and 24 weeks post-ART initiation (88.5% vs. 94.3%, p = .04) and maintain suppression throughout breastfeeding (74.3% [LPV/r] vs. 83.8% [EFV], p <.0001). Compared to EFV, women on LPV/r were significantly more likely to achieve virologic suppression (<40 copies/mL) by 8 weeks (96.6% [LPV/r] vs. 88.5% [EFV], p <.0001) and 24 weeks post-ART initiation (88.5% vs. 74.3%, p = .0002). Compared to EFV, women on LPV/r were significantly more likely to achieve CD4 count >200 cell/mm3 by 8 weeks (80% [LPV/r] vs. 61% [EFV], p <.0001) and 24 weeks post-ART initiation (96.6% vs. 74.3%, p <.0001). No differences were seen in rates of adverse events. No significant differences were seen in rates of stillbirths or congenital anomalies. DISCUSSION: Compared to EFV, women on LPV/r were significantly more likely to achieve virologic and immunologic suppression and maintain suppression throughout breastfeeding. Further studies are needed to confirm these findings in larger populations.

Infant Lopinavir/r Versus 3TC To Prevent Postnatal HIV-1 Transmission: The ANRS 12174 Trial

Chipepo Kankasa1, Nicolas Nagot2, 3, Nicolas Meda4, 5, James K. Tunweine6, Amwe Aku7, Debra Jackson7, Roselyne Vallo2, 8, Thorkild Tylleskar2, 8, Philippe Van de Perre2, 3, 8

ANRS 12174 Trial Group
1Department of Paediatrics and Child Health, University Teaching Hospital, Lusaka, Zambia, 2INSERM U1058, Montpellier, France, 3CHU Montpellier, Montpellier, France, 4Centre de Recherche Internationale pour la Santé (CRIS), Université de Ouagadougou, Ouagadougou, Burkina Faso, 5Centre Muraz, Bobo-Dioulasso, Burkina Faso, 6Department of Paediatrics and Child Health, Makerere University, Kampala, Uganda, 7School of Public Health, University of Western Cape, Cape Town, South Africa, 8Université de Montpellier I, Montpellier, France, 9Centre for International Health, University of Bergen, Bergen, Norway

Background: Strategies to prevent mother-to-child postnatal transmission of HIV-1 in Africa, including infant prophylaxis, have never been evaluated for the entire recommended period of breastfeeding, i.e. 12 months. Beside lamivudine, which proved safe and efficacious during 6 months for this purpose, lopinavir/ritonavir (LPV/r) is a good candidate for infant prophylaxis due to its good safety profile in infants, its potent antiretroviral activity and its high genetic barrier to HIV resistance mutations.

Methodology: The ANRS 12174 study is a randomised controlled trial comparing the efficacy and safety of prolonged infant peri-exposure prophylaxis (PreP) with lopinavir/ritonavir (LPV/r) versus lamivudine (3TC) to prevent postnatal HIV-1 transmission during the full duration of breastfeeding (50 weeks), in children born to HIV-1-infected mothers not eligible for ART (i.e. with CD4 < 350 cells/μL). In Burkina Faso, South Africa, Uganda and Zambia, seven days old HIV-uninfected breastfed newborns with birth weight > 2000g were randomised for either drug in a 1:1 ratio. The primary outcome was infant HIV infection at 50 weeks, diagnosed every 3 months by HIV-1 DNA PCR. Secondary outcomes included mortality, HIV-free survival and severe adverse events, including routine biological parameters. Outcomes were analysed using Kaplan-Meier survival methods with an intention-to-treat approach.

Results: Overall, 1273 children were enrolled in the trial, 636 in the LPV/r arm and 637 in the 3TC arm. Baseline infants’ characteristics were similar between arms. Antenatal maternal median CD4 count was 529 (IQR: 432-669). At final follow-up (completed in May 2013), 1119 (88.32%) infants had attended the final visit and 115 (9.08%) were lost to follow-up. The median duration of breastfeeding was 42 weeks (IQR:41-42). Overall, 17 HIV infections were diagnosed (of which 8 after 6 months), 8 in the LPV/r arm and 9 in the 3TC arm, and giving HIV infection rates of 1.39% (0.70 - 2.76) and 1.53% (0.80 - 2.91) at 50 weeks, respectively (p=0.83). Overall, 18 (2.83%) died in the LPV/r arm and 15 (2.35%) in the 3TC arm, respectively (p=0.57). HIV-free survival was similar between arms, at 96.5% (94.6-97.7) and 96.3% (94.4-97.5), respectively (p=0.85). Medical or biological severe adverse events were not different between arms.

Conclusions: Very low rates of HIV-1 postnatal transmission were achieved by using infant prophylactic LPV/r or 3TC for the whole duration of breastfeeding, without difference between the two drugs, which were both well tolerated. Infant PreP is a feasible and effective strategy to eliminate HIV transmission through breastfeeding. Further studies should evaluate the benefit of adding infant PreP to WHO option B+/B+ in order to prevent residual breastfeeding transmission.

Lower Newborn Bone Mineral Content Associated With Maternal Use of Tenofovir Disoproxil Fumarate

Friedman School of Nutrition Science and Policy, Tufts University, Boston, MA, United States, 10Department of Pediatrics, University of Illinois at Chicago, Chicago, IL, United States

Background: The impact of maternal tenofovir disoproxil fumarate (TDF) use on infant bone mass has not been well studied.

Methodology: Two groups of HIV-exposed, uninfected newborns >36 weeks gestational age (GA) were enrolled in this substudy of the US multisite Pediatric HIV AIDS Cohort Study. The TDF group included infants whose mothers used ≥8 weeks of TDF in the 3rd trimester; the nonTDF group included infants whose mothers used no TDF during the pregnancy. Within 4 weeks of birth, a whole body (WB) dual-energy X-ray absorptiometry (DXA) scan was obtained to measure WB bone mineral content (BMC) with head (WBWH) and less head (WBLH). Standardized analysis of scans was performed centrally. Maternal demographic/clinical data were prospectively collected. Infant weight/length were measured within 72 hours of birth. Target sample size was 75 (63 evaluable) per group to detect WBWH BMC difference between groups of 7% or 0.5 standard deviation (SD) with 80% power. Differences in covariates by TDF group were evaluated by Chi-square and Wilcoxon test. Linear regression models were fit to evaluate BMC by TDF group, adjusted and unadjusted for potential confounders.
Results: 74 TDF and 69 nonTDF group infants from 14 sites had evaluable DXA scans. Maternal TDF use varied by site (p<.001). Compared to the nonTDF group, TDF group mothers were more likely to be married (31% vs 22%, p=.035) and use boosted protease inhibitors (bPI) (86% vs 64%, p=.005); the groups were similar on demographics, infant weight (p=.159) and length (p=.21) z-scores and GA (p=.60). Among mothers with values available in 3rd trimester for CD4 (63 in TDF; 44 in nonTDF) and viral load [VL] (62 in TDF; 50 in nonTDF), similar proportions of TDF and nonTDF group mothers had CD4 ≥ 250 (94% and 93%, respectively) and VL < 400 copies/mL (90% and 90%, respectively). The unadjusted mean infant WBWH BMC was significantly lower in the TDF group (56g vs 64g, p=.002, 12.2%, 0.5 SD) as was the mean WBLH BMC (33 g vs 36g, p=.038, 8.3%, 0.3 SD). These differences persisted after adjusting individually for site; maternal bPI use, age, smoking, and pre-pregnancy body mass index; and infant GA, race/ethnicity, age at DXA and length. Maternal CD4 and VL during the 3rd trimester were not correlated with WBWH BMC (p=.44 and p=.13, respectively) or WBLH BMC (p=.29 and p=.34, respectively). Adjusted for site, maternal bPI use, age, and smoking, and infant body length, race/ethnicity and age at DXA, the mean WBWH BMC and mean WBLH BMC were lower in the TDF group than in the nonTDF group by 6.3g (p=.004) and 2.6 g (p =.056), respectively.

Conclusions: Maternal TDF use is associated with a significant reduction in neonatal BMC that persists after adjustment for other factors. The duration and clinical significance of this finding merit evaluation in longitudinal studies.

72 Virologic Control by 1 Year of Age Significantly Reduces HIV-1 Reservoirs in Perinatal Infection

Deborah Persaud1, Kunjal Patel2, Brad Karalus3, Carrie Ziemniak1, Kaitlin Rainwater-Lovett1, Ya Chen, Douglas D. Richman3, George K. Siberry4, Russell VanDyke5, Katherine Luzuriaga6, Pediatric HIV/AIDS Cohort Study (PHACS) and IMPAACT Network
1Pediatrics, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, 2Epidemiology, Harvard School of Public Health, Boston, MA, United States, 3Pathology and Medicine, University of California San Diego, San Diego, CA, United States, 4Eunice Kennedy Shriver National Institutes of Child Health and Human Development, Bethesda, MD, United States, 5Pediatrics, Tulane University Health Sciences Center, New Orleans, LA, United States, 6Pediatrics, University of Massachusetts Medical School, Boston, MA, United States

Background: Reducing proviral reservoir size is an important prerequisite for achieving HIV-1 remission for which antiretroviral therapy can be discontinued without viremic rebound. The extent to which proviral reservoir size can be substantially reduced with long-term, early combination antiretroviral therapy (cART) for perinatally HIV-infected (PHIV+) children is unknown.

Methodology: We quantified with droplet digital PCR proviral load in peripheral blood mononuclear cells (PBMCs) from 144 PHIV+ children enrolled in the Pediatric HIVAIDS Cohort Study/Adolescent Master Protocol (PHACS/AMP) who were receiving cART for a median of 10 years. Proviral burden, HIV serostatus, 2-LTR circles, and immune activation markers (soluble CD14, CD163, IFN-γ, IL-6, and IL-1β) were compared by age at virologic control (less than 1 vs. 1-5 vs greater than 5 years of age). Immune activation markers were also compared to perinatally-HIV-exposed, uninfected (PHEU) children. Proviral burden was also correlated with HIV serostatus and 2-LTR circles.

Results: When studied at 8-20 years of age, the proviral load of PHIV+ children who achieved virologic control by one year of age was significantly lower than that of PHIV+ children who suppressed between 1-5 years and after age 5 (p<0.001, Table 1); 46% of PHIV+ children who suppressed by one year of age had an undetectable proviral reservoir at <4 copies/million PBMCs compared to 11% of those who suppressed after age 1 (p=0.01). Lower proviral burden was associated with undetectable 2-LTR circles (p<0.001) and HIV-1 seronegative/indeterminate status (p<0.001). Plasma concentrations of soluble CD14, CD163, IFN-γ, and IL-1β were similar across the three age groups of virologic control (Table 1) but sCD14 and IL1β levels were significantly higher in PHIV+ children than in PHEU (p<0.001 and p=0.004 respectively).

Conclusions: Achieving virologic control by one year of age in perinatal infection leads to significantly smaller proviral reservoirs in those with HIV-negative or indeterminate serostatus and absent 2-LTR circles. It does not reverse immune activation. These findings emphasize the benefits of early therapy in perinatal infection with implications for a viro-immunologic profile for HIV cure-related clinical trials.

73 Virologic Efficacy of Efavirenz Maintenance Therapy in Nevirapine Prophylaxis-Exposed Children
Asnaf Coovadia1, Elaine Abrams2, Renate Strehlau1, Stephanie Shiau2, Francoise Pinillos1, Leigh Martens1, Gillian Hunt2, Wei-Yann Tsai2, Lynn Morris2, Louise Kuhn2, NEVEREST 3 Study Team
1University of the Witwatersrand, Johannesburg, South Africa. 2Columbia University, New York, NY, United States

Background: Ritonavir-boosted lopinavir (LPV/r)-based therapy is recommended as first-line for young children in low resource settings in part to circumvent drug resistance selected following nevirapine (NVP) prophylaxis. Whether prophylactic NVP exposure precludes later use of efavirenz (EFV) among children initially suppressed on LPV/r is unknown.

Methodology: NEVEREST 3 was designed as a randomized controlled trial to test whether transition to EFV maintenance therapy has equivalent virologic efficacy to standard continuation of LPV/r-based therapy in children infected despite exposure to NVP-containing prophylaxis. At Rahima Moosa Mother & Child Hospital in Johannesburg, South Africa, 298 children, exposed to NVP prophylaxis and aged 3-5 years were enrolled in a non-inferiority trial. All initiated LPV/r-based therapy <24 months of age and were suppressed <50 copies/ml (cpm) at enrollment. Children were randomized to switch to EFV or to continue on LPV/r. Children were followed with regular viral load, CD4 and other laboratory tests, growth measurements and clinical assessments to 48 weeks. Two primary endpoints were defined: 1) non-suppression i.e. RNA >50 cpm ever and 2) viral failure i.e. RNA >1000 cpm confirmed. The study was powered to rule out a difference between arms in virologic efficacy of ≥10%.

Results: Children were an average of 4.1 years of age, had initiated therapy at a mean of 9 months and had been on therapy for a mean of 3.5 years at the time of randomization. 150 children were randomized to switch to EFV and 148 to stay on LPV/r. Retention was 98%, there were no deaths and 2 children in the EFV and 3 children in the LPV/r arms were hospitalized during the course of follow-up. Both primary virologic endpoints were found to be non-inferior in the EFV arm relative to the LPV/r arm. In the EFV arm, 18% had non-suppression >50 cpm by 48 weeks vs. 28% in the LPV/r arm (delta=10; 95% CI: -0.4, 19.9). In the EFV arm 2.8% had viral failure (>1000 cpm confirmed) vs. 2.2% in the LPV/r arm (delta -0.6; 95% CI: -3.1, 4.3). Sleep difficulties were reported among 26% 4 weeks after the EFV switch but declined to <1% thereafter. There were no differences by arm in behavioral problems assessed by the Strengths & Difficulties Questionnaire (SDQ). CD4% and weight- and height-for-age remained in the normal range, similar by arm. Laboratory abnormalities and other complications were rare.

Conclusions: Children exposed to NVP prophylaxis who are initially suppressed on LPV/r-based therapy can safely transition to EFV-based maintenance therapy without increased risk of viral rebound. There are several advantages of the switch to EFV, including assisting adherence, simplifying tuberculosis treatment, preserving second-line options, avoiding metabolic toxicities, and reducing cost.

74LB Final Results of Koncert: A Randomized Noninferiority Trial of QD Vs BD LPV/r Dosing in Children
Hermione Lyall, KONCERT Trial Team
Imperial College London, London, United Kingdom

Background: Evidence for the efficacy of once daily (QD) ART for HIV-1 infected children/adolescents is limited. Ritonavir/ritonavir (LPV/r) is approved for use in adults once or twice daily, but twice daily (BID) in children.

Methodology: KONCERT was a randomized, non-inferiority PENTA trial in Europe, Thailand, Argentina and Brazil. Children (<18 yrs, >15kg) on LPV/r-containing ART with HIV-RNA (VL)<50 c/mL for ≥24 weeks were randomized to continue LPV/r BID or switch to QD dosing, according to FDA approved body weight-based dosing. Children were followed for minimum 48 weeks, visits at weeks 0, 4, 8, 12 then 12 weekly. The primary outcome was the percentage with confirmed VL>50 c/mL by 48 weeks, estimated using the Kaplan-Meier method (12% non-inferiority margin). 26 children falling outside the 80-125% limits for bioequivalence. GMR for Cmax was 1.13 (0.99, 1.28) and for Cmin was 0.18 (0.11, 0.29).

Results: 173 children were randomized to QD (86) or BID (87): 46% male, median age 11 (IQR 9-14) years; 25% white, 27% black, 35% Asian; 29% CDC stage C, median time on ART 7.2 years. Median baseline CD4% was 32% (IQR: 27, 36) QD vs 34% (28, 40) BID. Although all children had VL<50c/mL at screening, 12 (14%) QD vs 4 (5%) BID had baseline VL≥50 c/mL. By week 48 (1 QD child lost at week 4), 97% and 98% of time was spent on QD and BID respectively. 12 QD vs 7 BID children had confirmed VL≥50 c/mL within 48 weeks; the estimated percentage with VL rebound was 14% QD vs 8% BID: difference 6% (90% CI -0.4, 19.9, p=0.2); reducing to 4% (4-11) after adjustment for baseline CD4% and VL in a post-hoc analysis. No child died or had a new CDC C event. Two children who had a major PI mutation at VL rebound (L90M, M46I+V82A); 3 QD vs 2 BID children had M184V, 2 QD vs 2 BID developed TAMs. Changes from baseline to week 48 in CD4%, CD4 count, biochemistry, hematology and lipids were similar between arms, as were the number of children with grade 3/4 AEs (10 QD vs 7 BID, p=0.6). 14 (4%) QD vs 6 (2%) BID children/carers reported missing a dose within 3 days of any clinic visit (p=0.2). For the 26 QD children in the PK substudy, the geometric mean ratio (GMR) (90% CI) of AUCO-24 was 0.72 (0.61, 0.85) falling outside the 80-125% limits for bioequivalence. GMR for Cmax was 1.13 (0.99, 1.28) and for Cmin was 0.18 (0.11, 0.29).

Conclusions: Non-inferiority for VL suppression on QD versus BID LPV/r dosing was not demonstrated in this trial and LPV daily drug exposure was lower with QD dosing. Resistance and safety data were similar in both arms. Although the results can be partly explained by chance VL imbalance at baseline, they do not support the routine use of LPV/r QD in children and adolescents.
Very Early Combination Antiretroviral Therapy in Perinatal HIV Infection: Two Case Studies

Deborah Persaud1, Audra Devekis2, Hannah Gay1, Jagmohan Batra3, Tempe Chen2, David E. Michalik2, Kaitlin Rainwater-Lovett1, Carrie Ziemniak1, Katherine Luzuriaga4, Yvonne Bryson5

1Pediatrics, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, 2Pediatrics, Miller Children’s Hospital, Long Beach, CA, United States, 3Pediatrics, University of Mississippi Medical Center, Jackson, MS, United States, 4Pediatrics, University of Massachusetts Medical School, Worcester, MA, United States, 5Pediatrics, UCLA School of Medicine, Los Angeles, CA, United States

Background: Combination Antiretroviral treatment (cART) by 31 hours of age led to HIV remission in the Mississippi Child where cART cessation did not lead to rebound viremia. We report follow-up virologic and immunologic markers at 21 months off ART in the Mississippi Child and in a second perinatally-infected infant who started cART similar to that of the Mississippi Child (four hours of age) and remains on cART through age 8 months.

Methodology: Standard HIV DNA and RNA tests were used to confirm infection and assess virologic responses to cART. HIV-specific immune responses were assessed by ELISA, western blot and cytotoxic T-cell responses. CD4+ and CD8+ T cell percentages were enumerated by flow cytometry. Droplet digital PCR (DDPCR) was used to quantify proviral burden in peripheral blood mononuclear cells (PBMCs), resting CD4+ T cells, activated CD4+ T cells and monocytes. Replication-competent proviral genomes were identified using a limiting dilution viral outgrowth assay. Non-induced proviral genomes were quantified by DDPCR of culture-negative wells.

Results: The Mississippi Child has remained in remission with undetectable plasma viremia (<20 copies/mL) and normal CD4+ and CD8+ T cell counts at 39 months of age, 21 months after stopping cART. Trace proviral DNA is persistently detectable in PBMCs but replication competent HIV is not; non-induced proviruses were not detected in culture-negative wells. HIV-specific immune responses remain undetectable.

A second infant with high-risk exposure to HIV was started on cART at four hours of age. HIV infection was confirmed by positive peripheral blood HIV DNA PCR at four hours of life and HIV RNA of 217 copies/mL at 36 hours of age. HIV RNA was detected in CSF at 32 copies/mL on DOL#6. Plasma HIV RNA was undetectable on DOL#11 and remained undetectable through age 8 months. HIV DNA testing was negative by DOL#6, and remained undetectable at DOL#47 and 67. Replication-competent HIV was not recovered from resting CD4+ T cells at 1 and 3 months of age; non-induced proviral genomes were detected by DDPCR, in culture-negative wells, at one month but not age three months. At age 3 months, HIV antibody is indeterminate (western blot reactivity to gp160). CD4+ T cell percentages remained normal for age.

Conclusions: Very early cART in an HIV-infected infant led to sustained HIV remission through 39 months of age, 21 months after stopping cART. In a second infant, cART by four hours of life allowed rapid clearance of replicating virus and an undetectable proviral DNA by clinical assays within 6 days of life, supporting restriction of HIV spread with very early cART. Development of sensitive laboratory markers and standardized approaches will be necessary to guide the optimal management of very early HIV treated infants in order to achieve remission.

Pyroptosis Drives Both CD4 T Cell Death and Chronic Inflammation in HIV-Infected Lymphoid Tissues

Gilad Doitsh1, Nicole Galloway1, Xin Geng1, Kathryn Monroe1, Zhiyuan Yang1, Orlando Zepeda2, Peter Hunt1, Hiroyu Hatano2, Stefanie Sowinski1, Warner C. Greene1

1Gladstone Institute of Virology and Immunology, San Francisco, CA, United States, 2University of California, San Francisco, San Francisco, CA, United States

Background: The progressive loss of CD4 T cells in HIV-infected individuals is the over-arching cause of AIDS. Apoptosis is the mechanism by which productively infected CD4 T-cells die. In contrast, very little is known about how “bystander” resting CD4 T cells die in lymphoid tissues. These cells are refractory to productive HIV infection yet they account >95% of the CD4 T cell losses occurring in many lymphoid tissues like tonsil and spleen.

Methodology: Human lymphoid aggregated cultures (HLACs) were prepared using tonsil and spleen tissue; lymph nodes from consenting HIV-infected volunteers not on antiretroviral therapy were surgically excised and used in immuno-histological staining studies.

Results: Our finding demonstrate that productive HIV infection in activated CD4 T cells from tonsil and spleen (95%) leads to by caspase-1-mediated pyroptosis, an intensely inflammatory form of programmed cell death. In the pyroptotic death pathway, cytoplasmic contents and pro-inflammatory cytokines including IL-1β, are released into the extracellular space. Surprisingly, lymphoid CD4 T-cells, but not CD8 T cells or B cells in the same tissue, are primed to mount proinflammatory death responses as reflected by high-level expression of pro-IL-1beta. These events combine to create a vicious pathogenic cycle where dying CD4 T-cells release inflammatory signals that attract more cells to become abortively infected and die by pyroptosis causing further inflammation. Cell-to-cell transmission of HIV is obligately required to elicit this pyroptotic death response-cell free virions are ineffective Pyroptosis is efficiently blocked by VX-765, a small-molecule inhibitor of caspase-1 that has been shown to be safe in humans. Analysis of lymph nodes from HIV-infected subjects confirms caspase-1 dependent pyroptotic death of bystander CD4 T cells and release of IL-1beta.

Conclusions:
1. CD4 T-cell death in HIV-infected lymphoid tissues is principally controlled by caspase-1-mediated pyroptosis, an intensely inflammatory form of programmed cell death.
2. Pyroptosis provides a new and exciting nexus between CD4 T-cell death and inflammation with strong implications for HIV pathogenesis and disease progression.
3. Small-molecule inhibitors of caspase-1 could form a promising new “anti-AIDS” therapy that complements current treatment strategies by altering the detrimental host innate immune response to the virus rather than the virus itself.
Early ART Initiation Prevents Disruption of the Mucosal Barrier and Subsequent T-Cell Activation
Alexandra Schuett1, Yuwadee Phuang-Ngern1, Rungsun Rerkmititr2, Eugene Koon3, Nitya Chomchey3, Praphan Panuphak3, Merlin Robb5, Jerome Kim4, Mark de Souza1, Jintanat Ananworanich3, on behalf of the RV254/SEARCH 010 and RV304 Study Groups
1Retrovirology, USAMC-AFRIMS, Bangkok, Thailand, 2Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, 3SEARCH, Bangkok, Thailand, 4US Military HIV Research Program, Silver Spring, MD, United States

Background: Chronic HIV-infection is associated with damage of the intestinal epithelium partly by disrupting the Th17/Treg balance and contributing to systemic immune activation, a marker for disease progression. The initiation of anti-retroviral treatment (ART) early during acute HIV-infection (AHI) might represent an opportunity to intervene and limit destruction of the mucosal barrier.

Methodology: 38 subjects in Fiebig stages I to III were enrolled and underwent sigmoid biopsy at baseline, 6 months (29/38) and 24 months (17/38) post initiation of ART. Ten gender- and age-matched HIV uninfected (HIV-) and 5 ART-naïve chronically HIV+ subjects (CHI), 6 to 12 month post infection, served as controls. Mucosal mononuclear cells were isolated and subsequently stained for multi-parameter flow cytometry.

Results: At baseline, subjects were Fiebig stage: I (13), II (4) and III (21). A significantly lower frequency of Th17 cells was observed in FII compared to FI/II (Median 71.1% vs. 13.2%, p=0.03). No difference was seen between FI/II and HIV- (Median 13.2% vs. 14.5%, p=NS), while FII had lower Th17 cells compared to HIV- (Median 71.1% vs. 14.3%, p=0.01). Subjects who started ART in FI/II maintained frequencies of Th17 cells at 6 months (Median 13.5%) and 24 months (Median 12.7%) comparable to HIV-, while Th17 cells were depleted in (CHI) (Median 1.1%, p<0.001). Initiation of ART at FII prevented further loss of Th17 cells, but did not reconstitute Th17 frequencies to the level of HIV- (Median baseline: 71.1%, 6 months: 9.2%, 24 months: 8.1%, HIV- 14.5%). At 24 months subjects treated at FI/II and at FII maintained higher frequencies of Treg compared to HIV- (Median FII/II 6.7%, p=0.001 and FII 7.7%; p=0.003 vs. HIV- 3.1), but never increased to levels seen in CHI (Median 20.6%). Additionally, FII subjects showed significantly increased CD8 T cell activation before ART compared to HIV- as measured by HLA-DR/CD38 expression (Median 12.7% vs. 4.7%, p<0.001). However, at 6 and 24 months CD8 T cell activation decreased to frequencies similar to HIV- with 4.5% and 5.1%, respectively. FI/II subjects did not show an initial significant increase in CD8 T cell activation compared to HIV- (Median 6.9% vs. 4.7%, p=NS) and maintained low levels of immune activation at 6 and 24 months (Median 5.5% and 4.9%).

Conclusions: FII/II subjects exhibit levels of Th17 cells and CD8 T cell activation similar to HIV- subjects and maintain those levels under ART. Early initiation of ART may prevent the loss of Th17 cells and subsequent CD8 T cell activation thus contributing to the integrity of the mucosal barrier.

Characterizing the IFNα Resistance of Transmitted Founder HIV-1
Shilpa S. Iyer1, Angharad E. Fenton-May2, Andrew G. Smith1, Weiye Zheng1, John C. Kappes3, Feng Gao3, Frederic Bibollet-Ruche1, Hui Li1, George M. Shaw1, Persephone Borrow1, Beatrice Hahn1
1Departments of Medicine and Microbiology, University of Pennsylvania, Philadelphia, PA, United States, 2Nuffield Department of Clinical Medicine, Oxford, United Kingdom, 3Departments of Medicine, University of Alabama at Birmingham, Birmingham, AL, United States, 4Duke Human Vaccine Institute and Department of Medicine, Duke University Medical Centre, Durham, NC, United States, 5Nuffield Department of Clinical Medicine, University of Oxford, Oxford, United Kingdom

Background: Elucidating the host innate effector mechanisms that control HIV-1 replication at the site of entry during the earliest stages of infection could be instrumental in the development of an effective AIDS vaccine. We reported previously that transmitted founder (TF) viruses are more resistant to the antiviral effects of interferon α (IFNα) than viruses that predominate during chronic infection. Here, we used matched pairs of TF and 6-month (6-mo) consensus infectious molecular clones (IMCs) to identify genetic determinants of IFNα resistance.

Methodology: Single genome sequencing (SGS) was used to infer the full-length TF sequence as well as consensus sequences at 45 days, 85 days and 6-mo post-seroconversion from one patient (CH58). In addition, TF and 6-mo genome sequences were derived from 11 longitudinally followed patients (8 subtype C and 3 subtype B). IMCs were synthesized and viral replication was assessed in human CD4+ T-lymphocytes in the presence and absence of IFNα.

Results: To characterize the decline in IFNα resistance over time, we analyzed sequential IMCs from a single patient, CH58. In the absence of IFNα, all four viruses replicated with similar kinetics. However, when target cells were pretreated with IFNα, the TF; d45 and d85 viruses replicated nearly 10-fold more efficiently than the corresponding 6-mo virus (p<0.001). To determine whether loss of IFNα resistance was a common phenotype, we compared the replication potential of matched TF/6-mo pairs from 11 additional patients. In each case, TF viruses replicated more efficiently than the corresponding 6-mo viruses in the presence of IFNα. This difference was statistically significant (p<0.05) throughout the 11-day replication time course, with the greatest replication increase observed at day 7 post-infection (range 2.3 - 10.2 fold). This phenotype was reproduced in CD4+ T-lymphocytes from multiple human donors. Interestingly, we identified two distinct IFNα sensitivity profiles by varying the duration of pretreatment of target cells. For ten pairs, differential replication was observed when cells were pretreated from 4- 24 hours prior to infection, while two pairs only showed differential replication up to 16 hours of pretreatment, and not beyond. IFNα resistance mapped to nucleotide changes in different genes in two pairs.

Conclusions: These data demonstrate that antiviral genes up-regulated by IFNα exert significant selective pressure on the transmitted HIV-1 pool, resulting in the establishment of infection by variants that are relatively IFNα resistant. This IFNα resistance declines within 6 months of infection and is subtype independent. Multiple IFNα-stimulated genes likely contribute to this phenotype.
79LB Identification of IFI16 as HIV Restriction Factor

Amalio Telenti1, All Gawanbacht1, Dominik Hotter1, Christian Krapp2, Nitisha Pyndiah3, Greg Jordan3, Saren R. Paludan3, Martin R. Jakobsen3, Frank Kirchhoff2
1University of Lausanne, Lausanne, Switzerland, 2Institute of Molecular Virology, Ulm University Medical Center, Ulm, Germany, 3Institute of Molecular Virology, Ulm University Medical Center, Ulm, Germany, 4European Bioinformatics Institute, Cambridge, United Kingdom, 5Department of Biomedicine and Aarhus Research Center for Innate Immunology, Aarhus, Denmark

Background: Antiretroviral restriction factors are encoded by genes that are under strong positive selection pressure, induced in HIV-1 infection, and frequently interacting with viral proteins. Here, we used evolutionary genomics, transcriptomics, and protein interaction data to identify additional human genes showing these features and to characterize new restrictions factors.

Methodology: We first performed a genome-wide screen for genes under positive selection pressure in primates. The output was assessed in the context of orthogonal sets of transcriptome and protein interaction data. A cell-based assay was used to determine the impact of candidates on HIV-1 gene expression, virus production and virion infectivity. We monitored HIV-1 Gag and Env protein expression in the cells and in the culture supernatants by western blot analysis. Detailed analysis of the γ-interferon-inducible protein 16 (IFI16) included knockdown in primary cells, assessment of counteraction with viral accessory proteins and use of primate orthologs and a panel of viral strains and isolates. Silencing of IFI16, cGAS and STING was performed to distinguish between immune sensing activity and direct restriction.

Results: We identified 30 genes showing the signature of restriction factors. Overexpression of a strikingly high proportion of them inhibited transcription or translation of HIV-1, while a small subset impaired viral infectivity. Analysis of IFI16 demonstrated that this immune sensor of viral DNAs strongly reduces the production of infectious HIV-1 by interfering with LTR activity and Gag processing. This antiviral activity is conserved across different primate species, dependent on a nuclear localization signal, and counteracted by the viral Vpr protein. Silencing of IFI16 but not of other factors in the innate DNA sensing pathway, such as STING or cGAS, increased infectious virus production.

Conclusions: The number of human genes sharing the characteristics of known host restriction factors is very limited. The screen allowed the identification of IFI16 as an innate immunity factor that restricts HIV-1 independently of its DNA sensing activity.

80 Central Memory and Effector Memory CD4 T Cells From HIV Controllers Harbor Distinct HIV Strains

Eli Boritz1, Luke Swaszek1, Rebecca Hoh2, Jeffrey Martin1, Steven Deeks2, Daniel Douek1
1Human Immunology Section, Vaccine Research Center, Bethesda, MD, United States, 2Department of Medicine, University of California San Francisco, San Francisco, CA, United States, 3Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA, United States

Background: The distinct immunologic functions performed by CD4 T cells of central memory (CM) and effector memory (EM) phenotypes require distinct gene expression programs that could differentially affect HIV replication. We tested the difference between CM and EM cells as HIV hosts in vivo by quantifying and sequencing HIV genomes from these cellular subsets in a group of HIV-infected donors with spontaneous control of plasma HIV-1 RNA levels to <1,000 copies/mL in the absence of cART.

Methodology: CM and EM cells were sorted from PBMC of 6 HIV controllers by FACS. RNA genomes were extracted from plasma virions and reverse-transcribed. Env gene fragments were quantified and cloned from cell-associated DNA or virion cDNA using a novel, high-throughput single-genome amplification method termed fluorescence-assisted clonal amplification (FCA). Clonal sequences were checked for hypermutation using the Hypermut algorithm. Coreceptor specificities of clonal sequences were predicted using the Geno2pheno algorithm. Maximum-likelihood phylogenetic trees were reconstructed from alignments of non-hypermutant clonal sequences using the general time-reversible model of substitution with gamma distribution. Compartmentalization was assessed by Slatten-Maddison testing.

Results: Levels of HIV genomic DNA were indistinguishable in CM and EM cells from HIV controllers. By contrast, env DNA sequences from these two subsets diverged markedly, with genetic compartmentalization between CM and EM in all 6 controllers studied. No clonal sequence from any controller was predicted to be X4-tropic, and few sequences were hypermutant (CM median 3.9% of all sequences per donor, range 0-22.7%; EM median 2.15%, range 0-9.5%). Sequences from CM cells were more closely related to sequences from plasma virions than were sequences from EM cells, with CM/plasma compartmentalization in 3/6 controllers and EM/plasma compartmentalization in 6/6. Average genetic distances between groups of clonal sequences were smaller between CM and plasma than between EM and plasma. Phylogenetic trees from controllers but not from two untreated subjects with viral loads >20,000 copies/mL showed large clusters of matching sequences, often separated by large genetic distances. Several large clusters represented HIV clones with truncations in gp120, suggesting non-viable proviruses amplified by T cell clonal expansion.

Conclusions: The population of productively infected CD4 T cells in HIV controllers is very small. This is particularly true in the EM subset, where most cells harboring HIV DNA appear to have expanded from a few non-productively infected precursors. The key focus of ongoing HIV replication in controllers may be a tissue site containing CM-like cells.

81 Accelerated Viral Load Increase and CD4 Decline in HIV-1 Superinfected Women

Keshet Ronen1, Barbra Richardson1, Susan Graham1, Kishor Mandalaya2, Walter Jaeko1, Scott McClelland2, Julie Overbaugh1
1Fred Hutchinson Cancer Research Center, Seattle, WA, United States, 2University of Washington, Seattle, WA, United States, 3Coast Provincial General Hospital, Mombasa, Kenya, 4University of Nairobi, Nairobi, Kenya

Background: HIV superinfection (SI) has been detected at a substantial rate in several settings, but its impact on disease course remains poorly characterized. Understanding the consequences of SI has important implications for counseling HIV-infected individuals, as well as estimating transmission risk in epidemic modeling. Prior studies have suggested that SI may lead to a transient increase in viral load (VL) and sustained acceleration in VL increase
over time, however these studies were small (analyzing 2-12 cases of SI) or did not distinguish between coinfection and SI. We recently screened a cohort of HIV-infected high-risk women in Mombasa, Kenya, for superinfection. Among 145 women singly infected at baseline, 21 acquired SI during follow-up.

Methodology: Detailed clinical and laboratory data collected at quarterly intervals were used to compare disease progression between superinfected and singly infected women from the Mombasa cohort. Linear mixed effects models were used to compare post-acute VL and CD4 counts over time. Cox proportional hazards analysis was used to determine the effect of SI on time to clinical progression (CD4 < 200, ART initiation or death).

Results: Overall, 124 singly infected and 21 superinfected women contributed 925 person-years of follow-up, during which 1788 VL and 1532 CD4 counts were collected and 91 progression events occurred. VL increased more rapidly following SI than during single infection (increasing at 0.14 vs. 0.08 log10 copies/ml/year respectively, p=0.04). Conversely, CD4 counts decreased more rapidly in SI cases than singly infected women (at 1.57 vs. 0.97 √CD4 + cells/ml/year respectively, p=0.05). Prior to SI acquisition, there was a trend for ultimately superinfected women having lower setpoint VL than singly infected women (~0.37 log10 copies/ml, p=0.09). Adjustment for viral subtype, genital infection at HIV acquisition and HLA alleles reported to modify HI progression had negligible effect on the results. We did not detect a significant effect of SI on time to clinical events, though this may have been due to limited statistical power. We also did not detect transient changes in VL or CD4 at the time of SI detection, though sampling was not optimal for this analysis.

Conclusions: This is the largest study to date examining the effect of SI on HIV progression. Our findings suggest that SI may accelerate disease progression and, through elevated VL, increase infectivity, arguing for greater awareness among clinicians and patients of the consequences of SI. Additionally, the observation that VL setpoint may be lower pre-SI than in women who remain singly infected suggests that low initial viral replication may be associated with SI, prompting further investigation of viral fitness and immune responses in the setting of SI.

82 Selection for Active SAMHD1 Antagonism in Natural Infections of SIVagm
Chelsea Spragg1, Michael Emerman2
1Molecular and Cellular Biology, University of Washington, Seattle, WA, United States, 2Human Biology, Fred Hutchinson Cancer Research Center, Seattle, WA, United States

Background: The restriction factor SAMHD1, an effector of the innate immune response to viral pathogens, blocks retroviral reverse transcription in myeloid cells and resting CD4+ T-cells. Many retroviruses, including HIV-2 and other related Simian Immunodeficiency Viruses (SIVs), encode accessory genes that serve to counteract host SAMHD1 restriction by inducing the degradation of this antiviral factor. The viral accessory protein Vpr is responsible for SAMHD1 degradation in some lineages of lentiviruses, while in others, the related protein Vpx assumes this task. However, HIV-1 has no SAMHD1 degradation capability, leading to questions about whether or not there is a selective advantage to this activity.

Methodology: We used an evolutionary approach to examine the importance of SAMHD1 antagonism for viral fitness by studying adaptation to host in the context of natural SIV infections. Though African Green Monkeys (AGMs) comprise four related species, each population is infected with a distinct subtype of SIVagm, providing a unique opportunity to study the evolutionary forces governing virus-host interactions. We sequenced SAMHD1 from 50 AGMs representing four host species to identify SAMHD1 polymorphisms which could alter Vpr specificity. We then determined how Vpr proteins from different SIVagm subtypes are capable of mediating degradation of each of the different AGM SAMHD1 variants.

Results: We found multiple SAMHD1 haplotypes in AGMs which are differentially sensitive to degradation by Vpr from SIVagm subtypes. SIVagm Vprs are capable of inducing the degradation of the major SAMHD1 alleles found in their host population, but are often incapable of degrading SAMHD1 found in other populations. The specificity of Vpr for SAMHD1 involves both the N- and C-terminal regions of SAMHD1 and this specificity has evolved independently from adaptations of other Vpr proteins for their host SAMHD1.

Conclusions: We conclude that SIVagm has adapted to the SAMHD1 polymorphisms of the AGM population in which it is found. Evidence of viral adaptation to host restriction indicates that SAMHD1 antagonism is actively maintained in natural infections and that this function must be advantageous to viral fitness, despite its absence in HIV-1.

83 Probiotic and IL-21 Treatment Promotes Th17 Cell Recovery in ARV-Treatment of Pigtail Macaques
Alexandra M. Ortiz1, Zachary A. Klaase1, Kirby M. Carmack1, Carol L. Vinton1, Molly R. Perkins1, Francois Villinger1, Mirko Paiardini1, Jason M. Brenchley1
1LMM, NIH, Bethesda, MD, United States, 2Yerkes National Primate Research Center, Atlanta, GA, United States

Background: Loss of GI tract-resident, IL-17/IL-22-producing lymphocytes correlates inversely with HIV disease progression and often persists despite prolonged antiretroviral (ARV) therapy. Recent findings have indicated that incomplete immunological reconstitution following ARV-treatment stems from a persistent dysbiosis of commensal microbiota, which directly inhibits Th17 differentiation and maintenance. We have previously demonstrated that oral probiotics promote increased intestinal CD4+ T-cell reconstitution, but not Th17 recovery, during ARV treatment in a non-human primate model of HIV infection. In this study, we sought to promote Th17 cell recovery by administering IL21 to ARV-treated, probiotic-supplemented, SIV-infected macaques.

Methodology: We treated 11 SIVmac239-infected, pigtail macaques (PTM) at day 90 post-infection with the ARVs L812, PMPA and FTC and with or without probiotic (VSL#3) and IL21. We evaluated treatment efficacy by tracking SIV viremia by RT-PCR and systemic immune function by multi-parameter flow cytometry, ELISA and immunohistochemistry.

Results: Probiotic and IL21-supplementation of ARVs in SIV-infected PTMs promoted intestinal B-cell expansion, CD4+ T-cell reconstitution, and led to increased Th17 frequency and polyfunctionality. Our treatment was not associated with increased viral load nor was there evidence of increased immune activation. Importantly, treatment resulted in significantly fewer subclinical opportunistic infections and ARV-associated complications as compared to ARV-only control animals.
Conclusions: Our results are the first to demonstrate in vivo Th17 recovery in a non-human primate model of progressive HIV infection. By directly targeting microbial dysbiosis and defective Th17 differentiation, probiotic and IL21 supplementation to ARV treatment improved GI tract immunological functionality. Probiotic and IL21 supplementation of ARV treatment was well tolerated and further associated with reduced disease incidence as compared to ARV-only animals. We propose that combining ARVs with therapeutics aimed at restoring intestinal stasis will significantly improve disease prognosis of ARV-treated, HIV-infected, individuals.

Randomized Controlled Trials and Antiretroviral Resistance

84LB First-Line RAL + DRV/r Is Non-Inferior To TDF/FTC + DRV/r: The NEAT001/ANRS143 Randomised Trial
François Raffi1, Abdel G. Babiker2, Laura Richert3, Jean-Michel Molina4, Elizabeth C. George5, Andrea Antinori6, Jose Arribas7, Stefano Vella7, Geneviève Chêne7, Anton L. Pozniak7, NEAT001/ANRS143 Study Group
1University Hospital, Nantes, France, 2MRC Clinical Trials Unit at UCL, London, United Kingdom, 3INSERM U897, Bordeaux, France, 4St Louis Hospital, Paris, France, 5INMI L Spallanzani, Rome, Italy, 6Hospital La Paz, Madrid, Spain, 7Istituto Superiore di Sanità, Rome, Italy, 8Chelsea and Westminster Hospital, London, United Kingdom

Background: NEAT001/ANRS143 is a randomised, open-label, non-inferiority study comparing efficacy, safety and tolerability of darunavir/ritonavir (DRV/r) plus either raltegravir (RAL) or tenofovir/emtricitabine (TDF/FTC) in antiretroviral (ARV) treatment-näive HIV-infected adults. We present the final results from the trial, which involved 78 clinical sites from 15 countries.

Methodology: Primary outcome was time to first occurrence of failure defined as virologic (change of treatment before W32 because of HIV RNA viral load (VL) drop < 1 log10 copies/mL (c/mL) by W18 or VL ≥ 400 c/mL at W24, or confirmed VL ≥ 50 c/mL at or after W32) or clinical (death, AIDS, serious non-AIDS events) by W96. The pre-defined non-inferiority margin was an absolute difference of at most 9% for the failure rate of RAL vs TDF/FTC in the intent-to-treat (ITT) analysis estimated by Kaplan-Meier methods. Major secondary endpoints included safety, changes in CD4 and HIV RNA, and genotypic resistance.

Results: There were 805 patients (88% men), with median age 38 years, VL 4.77 log10 c/mL, CD4 333 cells/μL, and 123 weeks’ follow-up. Outcomes (RAL [n=401] vs TDF/FTC [n=404]) were as follows: 17.4% vs 13.7% met the primary endpoint (difference: 3.7%, 95% CI: -1.1%, 8.6%); 23.0% vs 19.8% either met the primary endpoint or stopped the randomised regimen for any reason (difference: 3.2%, 95% CI: -1.8, 8.2%); no significant difference in terms of serious adverse events (SAE) or grade 3 or 4 AE or treatment modifying AE (9.8 vs 8.0 per 100 person-years (py), log rank p=0.17; 9.5 vs 7.0 per 100 py, p=0.16; 4.1 vs 4.1 per 100 py, p=0.84, respectively). Percentage of participants achieving HIV RNA <50 c/ml over time from randomisation (ITT) is shown in the figure. Median CD4 increases at W96 were +267 (RAL) and +266 (TDF/FTC) cells/μL (p=0.92). Mean changes in creatinine clearance from baseline at W96 were +1.3 vs -4.1 mL/minute, p=0.004, and changes in total cholesterol/HDLc ratio were 0.0 vs 0.0, respectively (p=0.67). Treatment-emergent resistance was seen in 5/28 (RAL) vs 0/13 (TDF/FTC) patients with available genotype at failure.

Conclusions: The nucleotide/nucleoside-sparing regimen RAL + DRV/r was non-inferior to TDF/FTC + DRV/r in terms of W96 virological/clinical efficacy, with similar immunological reconstitution, safety and tolerability, in first-line ARV therapy.
85  Efficacy and Tolerability of Atazanavir, Raltegravir, or Darunavir With FTC/Tenofovir: ACTG 5257

1Center for Clinical AIDS Research & Education, University of California Los Angeles, Los Angeles, CA, United States, 2Harvard Center for Biostatistics in AIDS Research, Boston, MA, United States, 3Division of Infectious Diseases, Emory University, Atlanta, GA, United States, 4Janssen Therapeutics, Titusville, NJ, United States, 5Merck & Co, Whitehouse Station, NJ, United States, 6Gilead Sciences, Foster City, CA, United States, 7Bristol-Myers Squibb, Wallingford, CT, United States

Background: Non-nucleoside reverse transcriptase inhibitor (NNRTI) based antiretroviral therapy (ART) is not suitable for all HIV-infected persons. AS257, a randomized, open label trial, was designed to provide rigorous evaluation of virologic efficacy and tolerability of three NNRTI sparing preferred initial ART regimens.

Methodology: ART naïve persons ≥ age 18 years with HIV-1 RNA (VL) >1000 copies/ml (c/ml) without study regimen resistance were eligible. Subjects were randomized 1:1:1 to ATV (atazanavir 300 mg QD + ritonavir 100 mg QD [RTV]), RAL (raltegravir 400mg BID) or DRV (darunavir 800mg QD + RTV); all subjects received FTC/tenofovir QD. Subjects were followed until the last enrolled reached 96 weeks (w). The primary objective was to demonstrate regimen equivalence with regard to virologic efficacy and tolerability over 96w. The virologic endpoint was time to virologic failure (VF), defined from study entry to confirmed VL >1000 c/ml (w16 to before w24) or >200 c/ml (≥w24); time to tolerability failure (TF) was from entry to discontinuation of ATV, RAL or DRV for toxicity. 600 subjects per arm provided 90% power to show equivalence in pairwise comparisons. Equivalence was defined as a 2-sided 97.5% confidence interval (CI) on the difference in 96w cumulative incidence of VF entirely within ±10%; comparisons of TF and composite VF/TF were similarly defined. If equivalence was not shown, superiority was assessed by exclusion of 0 from the CI (pre-planned).

Results: 1809 eligible subjects enrolled: 34% non-Hispanic white, 42% non-Hispanic black, 22% Hispanic. 24% were women. Mean entry VL was 4.6 log10 c/ml; 69% had VL <100,000 c/ml. Mean baseline CD4 cell count was 308/mm3; CD4 was <200/mm3 for 30%. 92% of subjects completed 96w on study. ATV, RAL and DRV were equivalent with respect to VF (Fig a); VL was ≤50 c/ml in 88%, 94% and 89% for ATV, RAL and DRV, respectively at 96w (intent to treat). 14%, 1% and 5% discontinued ATV, RAL and DRV, for toxicity largely due to clinical jaundice and hyperbilirubinemia with ATV; other discontinuations were similarly distributed across arms. In comparisons of TF, ATV was inferior to RAL and DRV (b). For the composite VF/TF endpoint, RAL was superior to ATV and DRV; DRV was superior to ATV (c).

Conclusions: High and equivalent rates of virologic control were attained for all regimens. RAL was superior to both ATV (largely due to elevated bilirubin) and DRV (driven by both virology and differences in gastrointestinal toxicity) when considering TF and VF together.

86  Attachment Inhibitor Prodrug BMS-663068 in ARV-Experienced Subjects: Week 24 Analysis

Jacob Lalezari1, Gulam H. Latiff2, Cynthia Brinson1, Juan Echevarría1, Sandra Treviño-Pérez2, Johannes R. Bogner3, David Stock1, Samit R. Joshi1, George J. Hanna1, Max Lataliffe1, for the A438011 study team

1Quest Clinical Research, San Francisco, CA, United States, 2Maxwell Clinic, Durban, South Africa, 3Central Texas Clinical Research, Austin, TX, United States, 4Hospital Nacional Cayetano Heredia, Lima, Peru, 5Mexico Centre for Clinical Research, Mexico City, Mexico, 6Hospital of the University of Munich, Munich, Germany, 7Bristol-Myers Squibb, Wallingford, CT, United States, 8Bristol-Myers Squibb, Princeton, NJ, United States

Background: New antiretrovirals (ARVs) are needed for treatment-experienced (TE) HIV+ patients due to the development of resistance and the long-term safety and tolerability issues observed with existing agents. BMS-663068 is a prodrug of BMS-626529, an attachment inhibitor that binds directly to HIV-1 gp120, preventing the initial interaction between virus and host cell. This study is investigating the safety, efficacy and dose-response of BMS-663068 versus atazanavir/ritonavir (ATV/r) in TE HIV-1 infected subjects.

Methodology: A438011 is an ongoing Phase 2b, randomized, active-controlled trial, blinded to BMS-663068 dose. TE adults (≥1 week exposure to ≥1 ARV) with viral loads (VL) ≥1,000 c/ml and susceptibility to all study drugs (BMS-626529 IC50<100 nM) were randomized equally to four BMS-663068 groups (400 or 800 mg, BID; 600 or 1200 mg, QD) and a control group (ATV/r 300/100 mg QD), each with a background of raltegravir (RAL) 400 mg BID + tenofovir disoproxil fumarate (TDF) 300 mg QD. A lead-in monotherapy substudy was performed in approximately 10 subjects per BMS-663068 arm. The primary endpoints were the proportion of subjects with HIV-1 RNA <50 c/mL at Week 24 and the frequency of SAEs and AEs leading to discontinuations through Week 24.

Results: Overall, 254 subjects were randomized and 251 were treated across all arms. The median age was 39 years and 60% were male. The median VL was 4.85 log10 c/mL (43% of subjects had VL > 100,000 c/mL) and the median CD4 count was 230 cells/mm3 (38% had < 200 CD4 cells/mm3). Across
all arms, 20-40% had baseline NRTI/NNRTI resistance. Subjects electing to undergo 7 days of BMS-663068 monotherapy (n = 32) showed average VL reductions of 0.7 to 1.5 log_{10} c/mL at Day 8 (Table). Through Week 24, 69-80% of BMS-663068-treated subjects and 75% of ATV/r-treated subjects had HIV-1 RNA <50 c/mL (Table, modified Intent-To-Treat [mITT] FDA Snapshot). Similarly, 78-87% of subjects in the BMS-663068 arms had HIV-1 RNA <50 c/mL at Week 24 compared with 86% of subjects on ATV/r in the observed analysis (Table). All BMS-663068 doses were well tolerated and no SAEs or AEs leading to discontinuation were related to BMS-663068.

**Conclusions:** In a TE population, the attachment inhibitor BMS-663068, in combination with RAL and TDF, showed favorable safety and tolerability profiles, with similar efficacy in both mITT and observed analyses in comparison with ATV/r through Week 24. These results support the continued development of BMS-663068.

### 87 Sensitive Screening Reveals Widespread Underestimation of Transmitted HIV Drug Resistance

**Jin-fen Li, David Kim, Laurie Linley, Richard Kline, Walid Heneine, Jeffrey A. Johnson**  
Division of HIV/AIDS Prevention, CDC, Atlanta, GA, United States

**Background:** Our previous studies using sensitive testing to better assess transmitted HIV drug resistance were limited to a few large urban areas. Here we applied sensitive resistance screening on a population drawn from broader geographic regions and population densities in the United States.

**Methodology:** We used validated allele-specific PCR assays to screen 1070 de-identified plasma specimens collected in 2009-2011 within 3 months of HIV diagnosis from persons with no reported evidence of antiretroviral drug use. We focused on five RT mutations as sentinel markers of transmitted drug resistance, comprised of the historically frequently transmitted mutations, M41L, K103N, Y181C, and M184V, and a rare but clinically important mutation, K65R. The screening assays are capable of detecting resistant minority variants above random quasispecies noise at levels 10-100-times below what conventional bulk genotyping can detect. We determined the prevalence of transmitted resistance by demographic characteristics and used chi-square tests to compare percentages.

**Results:** Transmission prevalence of the five mutations with sensitive testing (16.6%) was 2.1-times that detected by conventional sequencing (7.9%) (p<0.0001). The increase was least for K103N (7.0% to 8.4%, 1.2-times), and greatest for K65R (0% to 1.7%). One-third of the K65R mutations were in samples with ≥1 of the other four mutations screened. The study population was 54% black, 29% white, 71% men who have sex with men (MSM), 14% female, and the major age group was 20-29 years (85% were black). By race/ethnicity, the prevalence of transmitted resistance by sensitive screening for whites (16.4%) and blacks (14.9%) were both significantly higher than for Hispanics/Latinos (6.4%) (p=0.005 and 0.013, respectively). By age, resistance prevalence was highest (23.1%) in those 13-19 years (85% were black) followed by 50-59 years (17.7%). Additionally, the 14.3% drug resistance prevalence identified in women (72% were black) was nearly the 15.1% prevalence observed for MSM (47% were black). Transmitted resistance prevalence in population densities of <50,000, 50,000-499,999, and ≥500,000 was 16.4%, 16.3%, and 13%, respectively (P=0.13).

**Conclusions:** The majority of transmitted resistance in this population was not detected by conventional testing. HIV transmission involving resistant virus was similar across genders and population densities. A substantial drug resistance burden was identified in the <20 year olds, who were predominantly black. The findings highlight the importance of sensitive testing for accurate drug resistance screening and underscore the importance of prevention efforts for at-risk youth.
Transmitted HIV-1 Drug Resistance Between Partner-Pairs

Joanne Stekler1, Rachel Payant1, Ingrid Beck3, Brandon Maust1, Sarah Holtz1,2, Janine Maenza1, Claire E. Stevens1, James I. Mullins1, Ann C. Collier1, Lisa M. Frenkel1,2
1University of Washington, Seattle, WA, United States, 2Seattle Children’s Hospital, Seattle, WA, United States, 3Fred Hutchinson Cancer Research Center, Seattle, WA, United States

Background: Population-based studies suggest that drug resistant HIV-1 is less likely to be transmitted than drug-susceptible viruses. We aimed to evaluate the likelihood of transmission of HIV-1 drug resistance between confirmed partner-pairs.

Methodology: Persons with primary HIV-1 infection have enrolled in an observational cohort at the University of Washington Primary Infection Clinic (PIC) since 1992. We attempted to identify sex partners of PIC enrollees. Partial gp120 env sequences were generated from transmitting and recipient partners, and relationships were confirmed by phylogenetic linkage and genetic distance analysis. Drug resistance mutations in pol encoding Pro and RT regions were assessed by pyrosequencing of >100 viral templates from plasma RNA and PBMC DNA from partner-pairs enrolled after 1995. We considered a mutation to be present if found in >1% of pyrosequences.

Results: Since 1992, 36 (72%) of 50 partner-pairs had genetically linked infections. Plasma RNA and PBMC DNA specimens for pyrosequencing were obtained from 31 male recipient partners a median of 23 (IQR 18-40) and 29 (IQR 21-52) days after infection, respectively. Plasma and PBMC specimens from the 30 male and one female transmitter were obtained a median of 22 (IQR 2-66) and 29 (IQR 2-94) days after the estimated date of HIV-infection of the recipient. 13 (42%) transmitters had 1-4 drug resistance mutations (total=25) detected at a median frequency of 6.0% (IQR 1.5-98.6%, range 1.0-99.5%). 11 of these 25 mutations were present in the HIV-1 population of the transmitter at a frequency >95%; 100% of these majority variants were detected in the recipient. 14 mutations were present as minority variants in the transmitter, ranging from 1.0-11.8% of the viral population; 2 (14%, 95% CI 1.8-42.8%) were detected in PBMCs of the recipient at levels above 1%. If drug resistance does not impact “transmission fitness” and if drug resistant variants are transmitted independently, then the probability of transmission would be dependent on the frequency of the variant in the viral population of the transmitter. In this case, the likelihood that two or more of the minority variants would have been identified in recipient partners is 5.3%, which is less than our point estimate but falls within the 95% CI. Requiring further investigation, 10 recipients had 12 mutations identified in PBMCs at a median of 2.0% (IQR 1.3-4.0, range 1.1-99.6%) that were not detected in plasma or PBMCs of the transmitter.

Conclusions: Drug-resistant HIV-1 variants are more likely to be transmitted when present as majority variants compared to those present as minority variants. This study does not support crude population-level data that HIV-1 drug resistance reduces “transmission fitness” compared to drug-susceptible viruses.

Silent Mutations in HIV-1 Subtype B Reverse Transcriptase Selected by ART Restore Viral Fitness

Sushama Telwatte1,2, Anna C. Hearps1,3, Adam Johnson1, Con Sonza4, Nicolas P. Sluis-Cremer5, Richard P. Harrigan5, Gilda Tachedjian1,2
1Centre for Biomedical Research, Burnet Institute, Melbourne, Australia, 2Department of Microbiology, Monash University, Melbourne, Australia, 3Department of Infectious Diseases, Monash University, Melbourne, Australia, 4Department of Microbiology and Immunology, University of Melbourne, Melbourne, Australia, 5Division of Infectious Diseases, University of Pittsburgh, Pittsburgh, PA, United States, 6Drug Treatment Program, BC Centre for Excellence in HIV/AIDS, British Columbia, BC, Canada

Background: Most mutations selected during antiretroviral therapy (ART) are non-synonymous (i.e. result in an amino acid change). However, silent mutations, K65K and K66K, in HIV-1 reverse transcriptase (RT) occur in over 35% of highly experienced patients and are among the most commonly selected mutations in subtype B strains. K65K/K66K are associated with thymidine analogue mutations (TAMs) including D67N+K70R and interrupt a homopolymeric nucleotide region introduced by D67N; however their impact in the context of HIV-1 replication is unknown. We hypothesise that silent mutations alleviate viral fitness defects conferred by D67N+K70R.

Methodology: The impact of K65K/K66K in the HIV-1 subtype B clone NL4.3 harboring the TAMs D67N+K70R on drug resistance and fitness was determined using in vitro drug susceptibility and growth competition assays. The mechanism of the fitness advantage conferred by K65K/K66K was assessed by analyzing virions produced by transfection and single-cycle infection assays, qPCR quantitation of intracellular reverse transcription products, and evaluation of cDNA synthesis efficiency by recombinant HIV-1 RT from RNA templates with D67N+K70R +/- K65K or K66K using a quantitative product enhanced reverse transcription (qPERT) assay.

Results: K65K/K66K did not alter susceptibility to zidovudine (ZDV), tenofovir (TFV), abacavir or nevirapine in MT-2 cells (p>0.05, n=4) or the infectivity of virus (normalized to p24) produced by transfection or from single-cycle infection assays. However, we found that K65K/K66K alleviated fitness defects conferred by D67N+K70R following multiple rounds of replication in the absence or presence of ZDV and TFV in MT-2 and in peripheral blood mononuclear cells. TAMs and silent mutations did not affect virion-associated RT activity or steady-state RT levels in virions produced by HIV plasmid transfection of MT-2 cells. No impact of K65K/K66K on early and late intracellular reverse transcription products in a single-cycle assay was detected. In contrast, using a highly sensitive qPERT assay, D67N+K70R in the RNA template resulted in an 8% decreased synthesis of a 111 nucleotide cDNA product compared to wild-type (WT) RNA (p=0.028, n=4) and this defect was restored by either K65K or K66K to WT levels.

Conclusions: Silent mutations in HIV-1 subtype B RT selected during ART alleviate fitness defects caused by TAMs and have no direct impact on drug susceptibility. The fitness advantage conferred by K65K/K66K is likely due to their ability to alleviate pausing by RT at homopolymeric stretches of nucleotides introduced by TAMs. Our study provides an explanation for why silent mutations are strongly selected in drug-treated individuals and supports their role as novel compensatory mutations in vivo.
90 Reduced In Vivo Replicative Capacity of Drug-Resistant SHIV During Acute Infection
Mian-er Cong, Chou-Pong Pau, Wald Heneine, J. Gerardo Garcia-Lerma
Division of HIV/AIDS Prevention, CDC, Atlanta, GA, United States

Background: Drug resistance mutations reduce replicative fitness in vitro but this impact remains poorly defined in vivo. To better understand the in vivo replicative capacity of drug-resistant viruses we used a macaque SHIV model and compared multiple viral markers of acute infection with either wildtype (WT) or drug-resistant SHIV containing the K65R or M184V resistance mutation.

Methodology: We measured plasma RNA (copies/ml) and proviral DNA (copies/10⁶ cells) during 10 consecutive weeks following peak viremia in macaques infected with site-directed SHIV162p3 mutants containing the M184V (n=4) or K65R (n=5) mutations associated with resistance to emtricitabine or tenofovir. Levels were compared with those seen in macaques infected with WT SHIV162p3 (n=5). Proviral DNA was quantified using a double-stranded primer assay coupled with co-amplification of RNase P gene as an internal PBMC control. Plasma RNA was quantified by an RT-PCR assay containing an internal normalizer. The correlation between log₁₀ transformed RNA and DNA levels was determined using the Pearson correlation coefficient. The slopes of the linear regressions were used to infer the ability of the viruses to initiate and spread infection. The effect of K65R and M184V on replicative capacity was evaluated in vitro using a competition assay with WT SHIV.

Results: SHIVK65R and SHIVM184V were rapidly outcompeted by WT SHIV in vitro with a decay half-life of 1.3 and 2.2 days, respectively. RNA and DNA levels correlated well during acute WT (r=0.98; p<0.0001), K65R (r=0.95; p<0.0001), or M184V (r=0.85; p=0.004) infections. Peak RNA but not DNA levels were significantly lower in K65R and M184V infections compared to WT infections (p<0.05). Viral RNA to proviral DNA ratios for K65R (1.8±0.2 log₁₀) and M184V (1.6±0.4 log₁₀) infections were also reduced by 90% and 93.7% relative to WT (RNA/DNA ratio of 2.8±0.2 log₁₀; p=0.006 and p=0.017, respectively).

Conclusions: In this well-controlled macaque model we show that measurement of viral RNA to proviral DNA ratios during acute infection reveals the in vivo effect of drug resistance mutations on virus fitness. Our findings documenting reduced acute replication of M184V and K65R mutants suggest that infection with these viruses has the potential to alter virus dynamics and influence disease progression.

91LB 744 and Rilpivirine as Two-Drug Oral Maintenance Therapy: LAI116482 (LATTE) Week 48 Results
David Margolis¹, Cynthia Brinson², Joseph Eron³, Gary Richmond⁴, Roger LeBlanc⁵, Marty St. Clair¹, Marita Stevens⁴, Peter Williams⁶, William Spreen¹
¹GSK, RTP, NC, United States; ²Central Texas Clinical Research, Austin, TX, United States; ³University of North Carolina, Chapel Hill, NC, United States; ⁴HIV Clinic, Ft. Lauderdale, FL, United States; ⁵Clinique Opus Inc, Montreal, QC, Canada; ⁶Janssen, Beerse, Belgium

Background: GSK1265744 (744) is an HIV integrase inhibitor (INI) under development as both an oral tablet and long-acting (LA) injectable. LATTE was designed to select an oral dose of 744 and to evaluate a two drug ART regimen with rilpivirine (RPV), as suppressive maintenance therapy. A separate study to evaluate 744 LA + RPV LA is planned.

Methodology: Phase 2b, multicentre, partially-blinded dose-ranging study in ART-naïve HIV infected adults, randomized 1:1:1:1 to the induction regimen of once daily 744 10 mg, 30 mg, 60 mg or efavirenz (EFV) 600 mg with TDF/FTC or ABC/3TC through W24, followed by a two drug oral maintenance regimen of 744 + RPV 25 mg through W96 (ongoing).

Results: 243 patients (Pts) were randomized and treated (ITT-E): 96% male, 38% non-white, 16%>100,000 c/mL HIV-1 RNA, 61% TDF/FTC. Plasma HIV-1 RNA declined rapidly across all 744 doses with no differences by NRTI. 744 Pts with a VL <50 c/mL immediately prior to W24 discontinued NRTIs and began RPV 25 mg; no change was made to the EFV arm. 207 Pts were treated in the ITT-Maintenance Exposed (ITT-ME) population. At W48, 82% of 744 + RPV Pts and 71% of EFV Pts were <50 c/mL by Snapshot (ITT-E). Amongst Pts who began 744 + RPV at W24, 93% were <50 c/mL by Snapshot at W48 (ITT-ME), with similar response rates for all 744 doses. Three virologic failures occurred during Maintenance (744 10 mg, 744 30 mg , EFV). One Pt on 744 10 mg + RPV, with very low 744 and RPV drug exposures, developed virologic failure at W48 with treatment-emergent INI (Q148R) and NNRTI (E138Q) resistance mutations. Drug-related AEs ≥ Grade 2 were reported by 14% and 19% of 744 and EFV Pts, respectively. Drug-related AEs ≥ Grade 2 during Maintenance were uncommon, 744 (4%) and EFV (4%). SAEs occurred in eleven 744 Pts (none related); and three EFV Pts (one related - suicide attempt). Fewer 744 Pts withdrew due to AEs (3%), than EFV Pts (13%). Treatment emergent max lab abnormalities ≥ Grade 3 occurred in 21% (744) and 31% (EFV) of Pts through W48. Rates of any graded ALT elevations were 17% (744) and 21% (EFV).

Conclusions: Oral 744 + NRTIs was well tolerated with good antiviral activity at all doses through W24. When used as maintenance therapy in virologically suppressed Pts, the two drug regimen 744 + RPV provided similar antiviral activity to EFV+NRTIs through the W48 primary analysis. 744 + RPV was safe and well tolerated across all 744 doses. These data support further development of 744 LA and the planned evaluation of 744 LA + RPV LA as an injectable regimen for HIV treatment.
**92LB Safety and Antiviral Effect of MK-1439, A Novel NNRTI (+FTC/TDF) in ART-Naive HIV-Infected Patients**

Javier O. Morales-Ramirez 1, Jose M. Gatell2, Debbie P. Hagins3, Melanie Thompson4, Keikawus Arastéh5, Christian Hoffmann6, Charlotte Harvey7, Xia Xu7, Hedy Teppler7

1Clinical Research Puerto Rico, San Juan, Puerto Rico, 2University of Barcelona, Barcelona, Spain, 3Chatham County Health Dept, Savannah, GA, United States, 4AIDS Research Consortium of Atlanta, Atlanta, GA, United States, 5EPIMED/Vivantes Auguste-Viktoria-Klinikum, Berlin, Germany, 6ICH Study Center, Hamburg, Germany, 7Merck, Whitehouse Station, NJ, United States

**Background:** MK-1439 is an investigational NNRTI active in vitro against both wild type HIV and most common NNRTI resistant variants at concentrations achieved with once daily (qd) dosing.

**Methodology:** Double-blind, randomized, dose-ranging study to examine the safety, tolerability and efficacy of 4 MK-1439 dose levels (25, 50, 100 and 200 mg qd) vs efavirenz (EFV) 600 mg qhs, each in combination with qd emtricitabine/tenofovir (FTC/TDF) in ART-naïve HIV-1 infected patients (pts) with baseline vRNA > 1000 c/mL, stratified by vRNA ≥ or <100,000 c/mL. The primary efficacy endpoint is the proportion of pts with vRNA <40 c/mL at week 24.

**Results:** Of 210 pts randomized, 208 were treated (n=40-43 per treatment group) and were of mean age 37 years, 91% male and 74% white; 12% had AIDS. Baseline vRNA was >100,000 c/mL in 28% of pts (median 4.6 log10 c/mL) and mean CD4 cell count was 417 cells/μL. Main week 24 results are shown below.

**Missing data approach:** Non-completer = Failure, Observed Failure

 Clinical adverse events (AEs) were reported by 135 (81%) of the 166 pts who received MK-1439 (any dose) and by 34 (81%) of the 42 pts who received EFV, and were considered drug-related (DR) in 35% and 57%, respectively. Serious AEs were reported in 3% and 7%, respectively; none were considered DR. The most common DR clinical AEs were abnormal dreams (9% of all MK-1439 pts; 7% of EFV pts), dizziness (3%; 24%), nausea (8%; 2%), fatigue (7%; 5%), and diarrhea (5%; 10%), and generally mild to moderate. The following DR AEs led to discontinuation in 2% of pts receiving MK-1439 (all doses) and 5% of pts receiving EFV: stupor, abdominal pain/nausea/insomnia, sleep disorder, and hallucinations (1 pt each) for MK-1439, and right-sided dysesthesia and hallucinations (1 pt each) for EFV. By week 8, CNS AEs (all causality) were seen in 18%, 35%, 14% and 15 %, in the 25mg, 50mg, 100mg, and 200mg MK-1439 groups (20% overall), and 33% in the EFV group. Grade 1 elevations in AST, ALT, LDL and total cholesterol were more common for EFV vs. any MK-1439 group.
Conclusions: In ART-naïve, HIV-1 infected pts, MK-1439 25, 50, 100, and 200 mg qd in combination with FTC/TDF demonstrated potent antiretroviral activity as compared with EFV, and was generally well tolerated at 24 weeks. No dose-response trend was observed for MK-1439; all MK-1439 dose groups had numerically greater virologic response rates than EFV. All groups showed increased CD4 counts. Safety and tolerability appeared comparable among the MK-1439 dosing groups, with fewer DR AEs compared with EFV.

TB and Other Coinfections

93 A Phase 2 Trial of a Rifapentine Plus Moxifloxacin-Based Regimen for Pulmonary TB Treatment
Marcus B. Conde1, Solange C. Cavalcante2,3, Margareth Dalcolmo1, Fernanda Melo1, Rafael Duarte1, Carla Loredo1, Valeria Rollo1, Betina Duromii1,3, Silvia Cohn1, Richard E. Chaisson1, Susan F. Dorman2
1Thoracic Diseases Institute, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil, 2Municipal Health Secretariat, Rio de Janeiro, Brazil, 3Instituto de Pesquisa Clinica Evandro Chagas, Rio de Janeiro, Brazil, 4Centro de Referencia Professor Hello Fraga, ENSP-Fiocruz, Rio de Janeiro, Brazil, 5Federal University of Rio de Janeiro, Rio de Janeiro, Brazil, 6The Johns Hopkins University School of Medicine, Baltimore, MD, United States

Background: Potent combination chemotherapy may allow reduction in duration of treatment required for drug-susceptible pulmonary TB. In the mouse model of TB treatment, intensive phase regimens containing rifapentine plus moxifloxacin have robust sterilizing activity. We assessed the antimicrobial activity, safety, and tolerability of a dual-substitution regimen containing rifapentine substituted for rifampin plus moxifloxacin substituted for ethambutol during the first 8 weeks (intensive phase) of pulmonary TB treatment.

Methodology: Adults with sputum smear-positive pulmonary TB were randomly assigned to an investigational regimen of rifapentine 7.5 mg/kg/day plus moxifloxacin 400 mg/day plus isoniazid and pyrazinamide (PMHZ), or a control regimen of rifampin 10 mg/kg/day plus ethambutol plus isoniazid and pyrazinamide (REHZ). Directly-observed treatment was administered 7 days/week for 8 weeks. Sputum was collected weekly for culture on solid Lowenstein Jensen (LJ) and liquid MGIT media. Outcomes were treatment discontinuations, adverse events, and stable culture conversion at the end of intensive phase. A modified intention-to-treat (MITT) group was comprised of participants with drug-susceptible TB, and a per-protocol group was comprised of MITT participants who in addition completed assigned treatment in ≥71 days and had an evaluable end-of-intensive phase culture.

Results: 121 participants were enrolled (69% male, 76% with cavitition on chest x-ray). Proportions of participants who discontinued assigned treatment for any reason were 9/62 (15%) in the PMHZ arm vs. 8/59 (14%) in the REHZ arm (p=0.88). Discontinuations due to toxicity were 4/62 (6%) in the PMHZ arm vs. 2/59 (3%) in the REHZ arm (p=0.44). A grade 3 or higher adverse event attributed to study treatment occurred in 6/62 (10%) in the PMHZ arm vs. 7/59 (12%) in the REHZ arm (p=0.70). Gastrointestinal, hepatic, and hematological toxicity did not differ between arms. In the MITT group, proportions with stable culture conversion at end of intensive phase on LJ medium were 51/60 (85%) in the PMHZ arm vs. 44/51 (86%, p=0.85) in the REHZ arm; and in MGIT medium were 39/46 (85%) in the PMHZ arm vs. 29/42 (69%, p=0.08) in the REHZ arm. In the per-protocol group, proportions with stable conversion at end of intensive phase in MGIT medium were 34/36 (94%) in the PMHZ arm vs. 27/37 (73%, p=0.01) in the REHZ arm.

Conclusions: The PMHZ regimen was well-tolerated and safe. The PMHZ regimen was more active than the REHZ regimen based on the surrogate endpoint of stable MGIT culture conversion at end of intensive phase. These results support evaluation of regimens containing rifapentine plus moxifloxacin for TB treatment shortening.

94 Tuberculosis Infection in Early Childhood in Uganda and the Influence of HIV Exposure
Carina Marquez1, Gabriel Chamie1, Jane Achan1, Anne F. Luettekemeyer1, Mary Kyeho1, Grant Dorsey1, Moses R. Kamya2, Edwin D. Charlebois1, Diane V. Havlir1
1University of California, San Francisco, San Francisco, CA, United States, 2Makerere University College of Health Sciences, Kampala, Uganda, 3Infectious Diseases Research Collaboration, Kampala, Uganda

Background: In high tuberculosis (TB) burden countries a significant proportion of the latent TB reservoir is established by age five; however, data on TB acquisition before age five is limited. Additionally, the risk of TB infection in HIV-exposed un-infected children (HEU), a growing group of children with a higher rate of mortality and impaired immune responses to infection compared to HIV-unexposed un-infected children (HUU), is unknown. We sought to address two knowledge gaps in the epidemiology of TB infection in early childhood: (1) the prevalence of TB infection in rural Uganda using an interferon gamma release assay (IGRA) and (2) the odds of TB infection in HEU vs. HUU children.

Methodology: We recruited children under 72 months from two well-characterized cohorts in Tororo, Uganda. We measured TB infection with the Quantiferon Gold in Tube IGRA (QFT-IT) and a tuberculin skin test (TST). A positive TST was defined as an induration greater than or equal to 10mm. QFT-IT positivity was not detected in children less than 11 months. QFT-IT positivity was 3% among children under 12 months, 12% among children 12-35 months, and 6% among children 36 to 72 months. HEU had a higher risk of TB infection as defined by positive TST or QFT-IT (OR 2.6 p=0.02) compared to HUU.

Results: The children's median age was 35.3 months (IQR: 14.1 –39.5). 76% of children had a BCG scar, and there was no difference when stratified by HIV-exposure. 21% of children had a positive TST, 7% had a positive QFT-IT, and 2% had an indeterminate QFT-IT. Discordance was high between TST and QFT-IT, κ=0.14. The proportion of TST positive children decreased with age (p=0.03): 32% among children under 12 months, 21% among children 12-35 months, and 13% among children 36 to 72 months. QFT-IT positivity was not detected in children less than 11 months. QFT-IT positivity was 3% among children under 12 months, 12% among children 12-35 months, and 6% among children 36 to 72 months. HEU had a higher risk of TB infection as defined by positive TST or QFT-IT (OR 2.6 p=0.02) compared to HUU.
Conclusions: HEU had an increased risk of TB infection compared to HUU. We detected positive QFT-IT results as early as 11 months, suggesting TB acquisition is detectable with this assay in early childhood. These data support intensified prevention efforts in early childhood, especially for HEU children.

95 Effect of Xpert MTB/RIF On Early Mortality in Adults With Suspected TB: A Pragmatic Randomized Trial
Gavin Churchyard1, Kerrigan McCarthy1, Katherine L. Fielding1, Wendy Stevens1, Violet Chithota2, Mark Nicol2, Norbert Ndijeka2, Alison D. Grant2, David Mametja2
1Aurum Institute, Johannesburg, South Africa, 2London School of Hygiene and Tropical Medicine, London, United Kingdom, 3National Health Laboratory Service, Sandringham, South Africa, 4University of Cape Town, Cape Town, South Africa, 5South African Department of Health, Pretoria, South Africa

Background: South Africa has phased in Xpert MTB/RIF, replacing sputum smear microscopy in laboratories, as the first-line diagnostic test for tuberculosis (TB). In a pragmatic cluster randomized trial, we evaluated the effect of Xpert on early mortality in persons with suspected TB.

Methodology: 20 laboratories in 4 provinces were randomized to intervention (immediate Xpert implementation) or control (microscopy, with Xpert implementation deferred) arms. At 2 primary health clinics served by each laboratory, a systematic sample of adults with suspected TB, identified by clinic staff, was invited to participate; demographic and clinical data relevant to TB and mortality risk were collected. Vital status after 6 months was determined by interview of participants or relatives and using the National Vital Status Register. The intervention effect on mortality risk was estimated using methods appropriate for cluster randomized trials with small number of clusters. An adjusted analysis was conducted to control for baseline differences of individual-level factors by study arm.

Results: Between June to November 2012, 4,972 persons with suspected TB were screened for the study. 4,712 (94.8%) were eligible and 4,665 (99.0%) contributed to the analysis. Of 4,665 participants (median age 36 years, 62% female, 93% South African), 76% (3,551) knew their HIV status, 62% (2,212/3,551) reported being HIV positive with a median self-reported CD4 count of 311 cells/mm³, 33% of whom reported ever being on ART, all similar by study arm. Participants in the intervention vs. control arm had lower socioeconomic indicators and were more likely to be asymptomatic (7.5% vs. 4.3%). Among 4,665 participants, 4,617 (99.0%) had known vital status at 6 months, with 208 deaths (4.5%). The 6 month mortality risk in the intervention and control arms were 3.9% (91/2,326) and 5.0% (117/2,339) respectively (risk ratio [RR] 0.86, 95% CI: 0.58, 1.27, p=0.42). After adjusting for age, sex, BMI, HIV status and factors imbalanced at baseline, the adjusted RR was 1.08 (95% CI: 0.73, 1.61; p=0.67). The 6 month mortality risk for self-reported HIV positive vs. –negative participants was 5.6% (124/2,212) and 1.9% (26/1,339) respectively (RR 2.63 (95%CI: 1.68, 4.12, p<0.001); and for HIV positive participants on vs. not on ART was 4.1% (30/730) and 6.3% (94/1,482) respectively (RR 0.63, 95% CI: 0.41, 0.97, p=0.03).

Conclusions: HIV prevalence and all-cause mortality were high among people with suspected TB, and mortality was not reduced by Xpert replacing smear microscopy in laboratories. Our data suggest that a sensitive diagnostic test needs to be supported by systems linking to appropriate care, particularly ensuring that people know their HIV status and those eligible, start ART promptly.

96LB Xpert as the First-Line TB Test in South Africa: Yield, Initial Loss To Follow-Up, Proportion Treated
Katherine L. Fielding1, Kerrigan M. McCarthy1, Helen Cox1, Linda Erasmus1, Sibuse Ginindza2, Anna Vassall2, Lindwe Msusi2, Chris Dye2, Alison D. Grant1, Gavin J. Churchyard1
1London School of Hygiene & Tropical Medicine, London, United Kingdom, 2Aurum Institute, Johannesburg, South Africa, 3University of Cape Town, Cape Town, South Africa, 4National Health Laboratory Service, Johannesburg, South Africa, 5South African Department of Health, Pretoria, South Africa, 6World Health Organization, Geneva, Switzerland

Background: South Africa has phased in Xpert MTB/RIF, replacing sputum smear microscopy in centralised laboratories, as the first-line test for tuberculosis (TB). In a pragmatic cluster-randomized trial, we evaluated the effect of Xpert implementation on yield, initial loss to follow-up and proportion treated.

Methodology: 20 laboratories in 4 provinces were randomized to intervention (immediate Xpert implementation) or control (microscopy; Xpert deferred) arms. At 2 primary health clinics per laboratory, a systematic sample of adults with suspected TB, identified by clinic staff, was enrolled. Laboratory results were obtained from the National Health Laboratory Service database, and TB treatment start dates from clinic registers or participant interview. Yield was defined as the proportion with a positive index Xpert or smear result. Initial loss to follow-up among participants with a positive index result was defined as not starting TB treatment within 28 days. The intervention effect was estimated using methods appropriate for cluster-randomized trials. An adjusted analysis controlled for baseline differences in individual-level factors.

Results: From June-November 2012, 4,972 persons were screened, and 4656 (93.6%) enrolled (median age 36yrs, 62% female). More participants in the intervention vs. control arm were asymptomatic (7.4% vs. 4.3%) and fewer had BMI<18.5 (8.7% vs. 12.3%). Among 4412 participants (94.8%) with a laboratory test result available, the yield was greater in the intervention vs. control arm (9.2% (200/2176) and 7.8% (174/2236) respectively, adjusted prevalence ratio 1.49 [1.00-2.32], p=0.05). Among 374 participants with a positive index test result, initial loss to follow-up was similar by study arm (intervention: 17% (34/200), control: 14.9% (26/174); adjusted risk ratio [aRR] 0.96, 0.48-1.93). Among 4656 participants, the proportion starting TB treatment by 6 months was similar by study arm (intervention vs. control: 10.8% (250/2324) vs 12.5% (291/2332) respectively, aRR 1.04 (0.76-1.43)).

Conclusions: Xpert increased the yield of TB by 49% but did not increase the proportion treated overall or reduce initial loss to follow-up. The increased yield has potential to be cost saving, and economic analyses are in progress. This analysis does not assess time to treatment rifampicin-resistant TB, which is a limitation. Maximising the benefit of Xpert scale-up requires strengthened health systems, particularly ensuring that people with positive test results start treatment promptly.
97LB 14 Day EBA Study of PA-824, Bedaquiline, Pyrazinamide and Clofazimine in Smear-Positive TB Patients

Andreas Diacon1, Rodney Dawson2, Christo Van Niekerk3, Jane Hutchings2, Stephen Murray3, Robert Schall1, Divan Burger1, Dan Evertt1, Carl Mendel1

1Department of Medical Biochemistry, Stellenbosch University, Cape Town, South Africa, 2Medicine, University of Cape Town Lung Institute, Cape Town, South Africa, 3Clinical Development, TB Alliance, Pretoria, South Africa, 4Clinical Development, TB Alliance, New York, NY, United States, 5Mathematical Statistics and Actuarial Science, University of The Free State, Bloemfontein, South Africa

Background: Bedaquiline (B) and PA-824 (PA) have demonstrated potent bactericidal activity in combination with clofazimine (C) and pyrazinamide (Z) in murine models of TB. C is currently in use for multi-drug resistant TB, but its efficacy has not been established in controlled clinical trials. This study evaluated the 14 day early bactericidal activity (EBA) of C and Z alone and in combination with B and PA.

Methodology: This prospective, randomized, open label trial randomized subjects with newly diagnosed smear positive pulmonary DS-TB into 7 parallel treatment arms of equal size: 1) Isoniazid, rifampicin, pyrazinamide and ethambutol (H-R-Z-E); 2) C; 3) Z; 4) PA-B-Z; 5) PA-B-Z-C; 6) PA-B-C; 7) B-Z-C. C was administered as 300 mg/day x 3d, then 100 mg/d x 11d. Subjects were evaluated through daily overnight sputum collections. Sputum was cultured on solid agar (CFU) and in liquid culture (TTP). The primary endpoint was the EBA CFU (0-14) as determined by the rate of change in logCFU per ml sputum over days 0-14 and the secondary endpoint was the rate of change in log TTP over days 0-14, both analyzed by a Joint Bayesian Non-linear Mixed Effects Regression Model (JB-NLME). Minimum inhibitory concentrations (MIC) for B, PA and C were determined by microtiter assay on isolates from baseline sputum samples. The time over MIC (TMIC) was determined using day 14 pharmacokinetic (PK) data with and without correction for plasma protein binding.

Results: 105 subjects (11 HIV+) were enrolled. H-R-Z-E had bactericidal activity similar to prior studies, with an EBA CFU (0-14)/day of 0.151, 95% CI [0.070; 0.231]. The PA-B-Z combination had an EBA CFU (0-14)/day of 0.167, 95% CI [0.078; 0.256]. C had no EBA by CFU or TTP and did not add to the bactericidal activity of the studied combinations. The MIC90 of the isolates from baseline were similar to prior reports, with B = 0.029 ug/mL in all arms, PA = 0.06-0.125 ug/ml and C = 0.125 - 0.25 ug/ml. The TMIC, calculated both with and without taking into account plasma protein binding for B and PA was 100% for the majority of patients. The TMIC for C, calculated without taking into account plasma protein binding was 100%, but taking into account plasma protein binding was 0%, for the majority of patients.

Conclusions: The PA-B-Z combination had robust EBA and will be taken in to a trial of longer duration. C did not have demonstrable EBA alone or in combination over 14 days of therapy. These results are consistent with the finding that the TMIC was nearly 100% for all subjects across arms for B and PA, but was 0% for most subjects for C, when plasma protein binding was accounted for.

98 CTX Prophylaxis Discontinuation Among ART-Treated Adults: A Randomized Non-Inferiority Trial

Christina S. Polyak1, Krista Yuhas2, Benson Singa3, Monica Khaemba3, Judd Walson2, Barbra Richardson2, Grace John-Stewart2

1Military HIV Research Program, Walter Reed Army Institute of Research, University of Washington, Bethesda, MD, United States, 2Global Health, University of Washington, Seattle, WA, United States, 3Kenya Medical Research Institute/ University of Washington, Nairobi, Kenya

Background: Cotrimoxazole (CTX) prophylaxis is recommended by the WHO for all HIV-infected individuals in settings with high prevalence of HIV and infectious disease. These guidelines were developed prior to scale-up of antiretroviral therapy (ART). Following ART, the threshold for CTX discontinuation after ART initiation remains undefined in resource-limited settings. We conducted a randomized clinical trial among adults on ART to determine whether discontinuation of CTX was non-inferior to continued CTX prophylaxis in decreasing morbidity.

Methodology: From February 2012 to September 2013, we conducted a non-blinded non-inferiority randomized clinical trial of CTX prophylaxis cessation versus continuation among HIV-infected adults who had been on ART for >18 months and had CD4 >350mm3 (Clinical trials registration NCT01425073). The study was conducted in a large HIV Treatment Program in Homa Bay, Western Kenya, a region with endemic malaria. Participants were randomized to continue or discontinue CTX using block randomization and followed 3-monthly for 12 months with systematic ascertainment of malaria, diarrhea and pneumonia morbidity. Malaria was defined as rapid diagnostic test (RDT) or smear positive with fever. Primary endpoint was a composite of morbidity (malaria, pneumonia, and diarrhea) and mortality. A secondary endpoint was severe adverse events (SAEs) grade 3 or higher. Incidence rate ratios (IRR) were estimated using Poisson regression with robust error variance. Analyses were intent-to-treat.

Results: Of 538 adults screened, 500 were eligible, enrolled and randomized; 250 to each arm. Median age was 40 years, 361 (72%) were women, and 442 (86%) of participants reported bednet use. Median enrollment CD4 count was 595 cells/mm3 and median ART duration was 4.5 years. These baseline characteristics did not significantly differ between arms. Retention was high with 245 (98%) participants completing 12-month follow-up in each group. Combined morbidity/mortality was significantly higher in the CTX discontinuation arm (IRR=2.27, 95% CI: 1.52-3.38; p<0.001), driven by malaria morbidity. There were 34 cases of malaria, 33 in the CTX discontinuation arm (IRR=33.02, 95% CI: 4.52-241.02; p=0.001). Diarrhea and pneumonia rates did not differ significantly between arms (IRR=1.36, 95% CI: 0.82-2.27, and IRR=1.43, 95% CI: 0.54-3.75, respectively). Rates of SAEs ≥Grade 3 did not differ significantly between arms (IRR=2.00, 95% CI: 0.90-4.44), with limited power to detect a difference.

Conclusions: CTX discontinuation among ART-treated adults in a region with endemic malaria results in increased incidence of clinical malaria but not pneumonia, diarrhea or combined severe SAEs compared to those who continue CTX.
**HIV and Elevated Cancer-Specific Mortality Following Cancer Diagnosis in the United States**

Anna E. Coghill, Meredith S. Shiels, Eric A. Engels
Division of Cancer Epidemiology and Genetics, National Cancer Institute, Washington, DC, United States

**Background:** HIV-infected individuals remain at increased cancer risk, despite advances in HIV treatment. In fact, prolonged life expectancy due to effective HIV treatment has resulted in greater numbers of HIV-infected persons reaching ages where cancer incidence is elevated. The combination of this increased opportunity to develop cancer at older ages as well as the established etiologic link between HIV and cancer incidence has resulted in an increasing number of individuals diagnosed with both diseases. This warrants examination of the role HIV may play in altering cancer patient survival, a question inadequately answered to date.

**Methodology:** We identified cancer cases from 5 U.S. cancer registries participating in the HIV/AIDS Cancer Match Study. HIV status of cancer patients was determined through linkage with HIV registries. We assessed cancer-specific mortality by HIV status, with survival time calculated from cancer diagnosis to either cancer death, censoring due to death from other causes, or last date of registry follow-up. Cox models included HIV as a time-varying covariate and adjustment for age, gender, year of cancer diagnosis, and cancer stage.

**Results:** The number of cancer cases with HIV infection ranged from 137 for kidney cancer to 2,884 for non-Hodgkin lymphoma (Table 1). Following cancer diagnosis, cancer-specific mortality was significantly elevated in HIV-infected compared to HIV-uninfected patients for most cancers. This adverse association was present for AIDS-defining cancers, i.e. non-Hodgkin lymphoma (hazard ratio=1.25) and cervical cancer (1.36), as well as for commonly diagnosed non-AIDS-defining cancers, i.e. colorectum (1.41), lung (1.24), breast (3.75), and prostate (2.50).

**Conclusions:** HIV-infected cancer patients experienced higher cancer-specific mortality than HIV-uninfected cancer patients, a trend observed across multiple cancer types, independent of cancer stage. HIV infection could affect cancer mortality through biological effects on the tumor environment. Additionally, HIV-infected individuals may receive sub-optimal cancer treatment. As the number of HIV-infected patients diagnosed with cancer continues to increase, whether HIV results in excess cancer mortality is an increasingly relevant question. Our study was the largest and most comprehensive investigation of HIV and cancer mortality to date and suggests that future research into this relationship is warranted.

100 Impact of Kaposi Sarcoma On Survival in HIV-Infected African Adults On Antiretroviral Therapy
Stephen B. Asiimwe1,2, Miriam Laker-Oketta1,3, John Bennett4, Adrienne Mocello5, David Glidden6, Jessica Haberer6, Mwebesa Bwana1, Peter Hunt1, David Bangsberg4, Edward Mbiisse1, Jeffrey Martin1
1Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA, United States; 2Department of Internal Medicine, Mbarara Regional Referral Hospital, Mbarara, Uganda; 3Infectious Diseases Institute, Kampala, Uganda; 4Department of Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, MA, United States

Background: In sub-Saharan Africa (SSA), Kaposi’s sarcoma (KS) remains one of the most common malignancies amongst HIV-infected adults. In resource-rich areas, we now know that survival after KS diagnosis has markedly improved in the ART era, and, in fact, ART alone is often initiated for KS in the absence of immediately life-threatening complications. In SSA, ART alone is also often administered for persons with KS, but we know little of the effectiveness of this strategy.

Methodology: We performed a cohort analysis of HIV-infected adults initiating ART in Uganda from 2007 to 2011. Subjects with KS were derived from the Antiretrovirals for Kaposi’s Sarcoma clinical trial, which enrolled ART-naïve patients with biopsy-confirmed KS who did not urgently require chemotherapy. The comparator group was subjects without KS from the Uganda AIDS Rural Treatment Outcomes Cohort, based in Mbarara, Uganda; these were consecutive patients initiating ART for indications other than KS. Measurements on both groups were obtained using the same questionnaires and laboratories. Observation was from ART initiation to either death, loss to follow-up, or administrative closure at 4 years.

Results: We evaluated 467 subjects (224 with KS/243 without). Median values for the combined population at the time of ART initiation were: age 34 years (IQR: 28-40), CD4+ T-cell count 135/mm^3 (IQR: 59-230), and plasma HIV RNA 147,993 copies/ml (IQR: 52,164-352,420). Subjects were observed for a median of 3.6 years (IQR 1.9-4.0) with 6.9% lost to follow-up. In an unadjusted analysis, cumulative mortality at 4 years was 30% in the KS group compared with 6.5% in the non-KS group (Figure). In proportional hazards regression models adjusting for age, sex, socio-economic status, mental and physical health status, history of opportunistic infections, body mass index, hemoglobin, CD4 count, and plasma HIV RNA level at ART initiation, patients with KS had a 4.0-fold (95% CI: 1.6-9.7; p =0.003) higher rate of death in the first year after ART and a 2.8-fold higher rate (95% CI: 0.92-8.2; p = 0.07) thereafter.

Conclusions: Among HIV-infected adults initiating ART in Uganda, those with KS experienced substantially higher mortality than those without KS, indicating that treatment with ART alone for all comers with KS is suboptimal. The findings call for improved prognostic staging, and increased access to potent chemotherapy, or development of new adjunctive therapy for KS in resource-poor settings.

101 Prospective Characterization of Kaposi Sarcoma Herpesvirus Inflammatory Cytokine Syndrome
Mark N. Polizzotto1, Thomas S. Uldrick1, Kathleen M. Wyvili3, Karen Aleman1, Vickie Marshall1, Denise Whitby2, Stefania Pittaluga3, Seth Steinberg4, Irini Sereti5, Robert Yarchoan6
1HIV and AIDS Malignancy Branch, National Cancer Institute, Bethesda, MD, United States; 2Viral Oncology Section, Frederick National Laboratory for Cancer Research, Frederick, MD, United States; 3Laboratory of Pathology, National Cancer Institute, Bethesda, MD, United States; 4Biostatistics and Data Management Section, National Cancer Institute, Bethesda, MD, United States; 5HIV Pathogenesis Unit, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

Background: Kaposi sarcoma herpesvirus (KSHV) is the cause of Kaposi sarcoma (KS), primary effusion lymphoma (PEL), and a form of multicentric Castleman disease (MCD), each associated with HIV. Recently a novel KSHV-associated inflammatory syndrome distinct from KSHV-MCD was described: KSHV inflammatory cytokine syndrome (KICS). We report characteristics of the first ten patients prospectively studied with KICS, separate from the original six, and compare them with control cohorts.

Methodology: We evaluated adults with clinical abnormalities potentially due to KICS, including FDG-PET/CT and biopsy to exclude alternate explanations such as KSHV-MCD. Those meeting the protocol case definition were followed and compared with two prospectively characterized control cohorts: 20 HIV/KSHV-coinfected adults and 20 HIV-infected adults not known to be KSHV-infected, each stratified by HIV viremia (10 with HIV VL ≤50copies/mL and 10 with >10,000 in each). Comparisons were made by Wilcoxon rank-sum for continuous parameters and Cochran-Armitage for symptom severity; given multiple comparisons p <0.005 was taken as significant and 0.005 <p <0.05 trend toward significance. Study registered as NCT1419561.
Quadrivalent HPV Vaccine Demonstrates Immune Memory in HIV-1-Infected Men

Timothy Wilkin*, Shelly Lensing†, Mark Einstein‡, Jeannette Lee§, Stephen Goldstone∥, Elizabeth A. Stier∥, Michael Berry∥, Naomi Jay∥, Ronald Mitsuyasu∥, Joel Palefsky∥

*Division of Infectious Diseases, Weill Cornell Medical College, New York, NY, United States; †Department of Biostatistics, University of Arkansas for Medical Sciences, Little Rock, AR, United States; ‡Department of Obstetrics & Gynecology and Women’s Health, Albert Einstein College of Medicine and Montefiore Medical Center, New York, NY, United States; §University of Arkansas for Medical Sciences, Little Rock, AR, United States; ∥Icahn School of Medicine at Mount Sinai, New York, NY, United States; ¶Department of Obstetrics and Gynecology, Boston University Medical Center, Boston, MA, United States; ‡Department of Medicine, University of California San Francisco, San Francisco, CA, United States; ∥University of California San Francisco, San Francisco, CA, United States; ¶UCLA CARE Center, University of California Los Angeles, Los Angeles, CA, United States

Background: HIV-1-infected men are at a highly increased risk of HPV-related cancers. Prior studies have shown that HPV vaccination is safe and immunogenic in this population. The duration and quality of the immune response in the setting of HIV is unclear. Immune memory from a vaccine is a vigorous immune response upon re-exposure to the relevant antigen. This confers long-term protection against the pathogen.

Methodology: 103 HIV-1-infected adult men received a standard 3-dose series of the quadrivalent HPV vaccine at weeks 0, 8 and 24. 73 participants consented to an extension protocol and received a 4th vaccine dose at week 128. Serum neutralizing antibody concentrations were measured using a competitive Luminex assay at week 0, week 28 (4 weeks after completing 3-dose series), week 76, week 128 (just prior to 4th dose), week 129 and week 132.

Results: All 10 KICS subjects were HIV infected males; median (range) age 36 (22-60); HIV VL 72copies/mL (<50-74375; <50 in 5/10), CD4 88/μL (7-1308); KS in 10/10; PEL in 2/10. Number clinical abnormalities present 8 (6-11), worst symptom CTCAE grade 3 (2-4). Symptoms included: gastrointestinal (present in 9/10); edema (9/10); respiratory (6/10); effusion (5/10); adenopathy (4/10); neurologic (3/10); fever (2/10). Lab abnormalities included anemia (all); hypoalbuminemia (all); thrombocytopenia (6/10); leukopenia (4/10) and elevated CRP (all). None developed MCD over 2-36 months; 6 died (4 of KSHV-associated tumors), 4 remitted with therapy. KICS subjects compared with both HIV stratifications within each control group had more severe symptoms; lower hemoglobin and albumin; higher CRP; elevated KSHV VL; and elevated IL-6 and IL-10 (see table).

Conclusions: KICS subjects demonstrated diverse severe clinical abnormalities, a high rate of intercurrent KSHV-associated tumors, and high mortality. KSHV VL and an IL-6/IL-10 cytokine signature were elevated even compared with HIV viremic controls. KICS may be an important unrecognized cause of morbidity and mortality, including some symptoms previously ascribed to HIV, and warrants further exploration of KSHV-directed therapy.

102 Quadrivalent HPV Vaccine Demonstrates Immune Memory in HIV-1-Infected Men
**HIV-1 Infection Alters Intestinal Expression of Antiretroviral Drug Transporters and Enzymes**

Olena Kis1, Md. Tozammel Hoque1, Sharon L. Wamsley1,2, Sumathi Sankaran-Walters3, Satya Dandekar4, Reina Bendayan1

1Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada, 2University of Toronto, Toronto, ON, Canada, 3Division of Infectious Diseases, University Health Network, Toronto, ON, Canada, 4Medical Microbiology and Immunology, University of California, Davis, CA, United States

**Background:** HIV-1 infection is associated with intestinal tissue pathology and inflammation, which may alter the functional expression of drug transporters and metabolic enzymes known to be involved in antiretroviral drug disposition and intestinal absorption. This study investigated the effect of HIV-1 infection and/or chronic antiretroviral therapy on the expression of intestinal drug transporters and metabolic enzymes.

**Methodology:** Human intestinal biopsy tissues were obtained from i) HIV+ patients receiving atazanavir-based antiretroviral treatment (viral load <50 copies/mL), N=7; ii) HIV+ patients, therapy-naive (VL &gt;10,000 copies/mL, CD4+ &lt;500 cells/μL), N=7; and iii) age-matched healthy individuals, N=7. Expression of intestinal drug transporters, such as P-glycoprotein (Pgp), multidrug-resistance associated proteins (MRPs), breast cancer resistance protein (BCRP), and organic anion transporting polypeptides (OATPs), as well as cytochrome P450 enzymes (CYP3A4, CYP2B6) was examined by real-time qPCR, immunoblotting, and immunohistochemistry analysis.

**Results:** Compared to uninfected subjects, antiretroviral-naive HIV+ patients had significantly lower mRNA expression (2-4 fold) of CYP3A4, MRPP (ABCC2), and OATP2B1 (SLCO2B1) genes. Several other genes (e.g., Pgp (ABCB1), BCRP (ABCG2)) also showed a trend towards downregulation. In antiretroviral-treated group, CYP3A4, Pgp, MRPP, and BCRP expression was partially restored to healthy levels; however, high inter-individual variability in expression was observed in this group. Immunohistochemistry analysis of CYP3A4 and MRPP expression in paraffin-embedded tissue slices confirmed downregulation of these genes in HIV-infected patients.

**Conclusions:** Expression of drug-metabolizing enzymes and drug transporters differs between antiretroviral-naive HIV+ patients and uninfected subjects. These findings are in agreement with studies reporting regulation of these drug transporters and drug-metabolizing enzymes by HIV-1 associated pathogenesis and inflammation in other organs and blood-tissue barriers. Since many antiretroviral drugs are substrates of CYP3A4 (Pis, NNRTIs, maraviroc), Pgp (Pis, NRTIs, integrase inhibitors, maraviroc), MRPs (Pis, NRTIs), and BCRP (NRTIs, raltegravir), these data suggest that the pharmacokinetics of these drugs may differ in HIV-infected patients when compared to healthy volunteers. Overall, antiretroviral pharmacokinetics data and drug-drug interactions assessed in healthy volunteers should be interpreted with caution as they may not reflect antiretroviral drug disposition in HIV-1 infected patients. This study is supported by the Canadian Foundation for AIDS Research.

**Tenofovir-Emtricitabine Directly Observed Dosing: 100% Adherence Concentrations (HPTN 066)**

Craig W. Hendrix1, Adriana Andrade1, Angela D. Kashuba2, Mark Marzinke1, Peter L. Anderson3, Ayana Moore4, Vanessa Elharrar1, Lei Wang5, Kenneth H. Mayer4, Kristine B. Patterson4

1The Johns Hopkins University, Baltimore, MD, United States, 2University of North Carolina (Chapel Hill), Chapel Hill, NC, United States, 3University of Colorado, Aurora, CO, United States, 4FHI 360, Durham, NC, United States, 5National Institutes of Health, Rockville, MD, United States

**Background:** Oral pre-exposure prophylaxis trials have yielded disparate efficacy results attributable largely to variable adherence. Objective adherence benchmarks are needed. HPTN 066 was conducted to establish drug concentrations associated with 100% adherence by using directly observed tenofovir (TFV) disoproxil fumarate (TDF)/emtricitabine (FTC) dosing with variable frequency.

**Results:** The median age of participants was 45 years (interquartile range [IQR] 37-51). 63% were White, 17% Hispanic, 13% Black, 5% Asian. 84% were receiving ART; 83% had a plasma HIV RNA &lt;200 copies/mL; the median CD4 was 517 cells/mm3 (IQR 423-68). Antibodies to HPV types 6, 11, 16, and 18 were detected in 39%, 30%, 26% and 18% prior to the first HPV vaccine increasing to 97%, 98%, 99%, and 96% at week 28. The seropositivity declined to 95%, 96%, 95% and 63% over the next two years. Four weeks after the 4th vaccine dose, antibodies were detected in 100%, 100%, 100% and 94%, and the geometric mean titers (GMT) were significantly higher than those of week 28 for HPV 16 and 18 (P=.002 and P=.001, respectively) suggesting a strong anamnestic immune response. Anti-HPV GMT titers during study follow-up are shown in Figure 1.

**Conclusions:** The quadrivalent HPV vaccine induces an anamnestic response in HIV-1-infected men. Antibody concentrations declined for two years after completing vaccination, but responded quickly after a challenge of a repeat vaccination. This suggests the development of immune memory, which often correlates with long-lasting protection for other vaccines.
**Methodology:** Healthy, HIV- men and women were randomized 1:1:1:1 to 4 oral TDF 300 mg/FTC 200 mg regimens: 1 tab daily, 2 tabs twice weekly, 1 tab twice weekly, or 1 tab weekly, each for 5 weeks with all doses observed. Trough plasma TFV and FTC, peripheral blood mononuclear cell (PBMC) TFV-diphosphate (TFV-DP) and FTC-triphosphate (FTC-TP) were assessed by UPLC-MS/MS from blood collected prior to the 2nd dose, weekly for 5 weeks, and 2 weeks after the final dose. Tissue biopsies for TFV, FTC, TFV-DP, and FTC-TP concentrations were collected on week 5 and 7 in half the participants.

**Results:** Thirty-nine participants were evaluable. Steady-state concentrations (Table, median [interquartile range]) were achieved with the 2nd dose for plasma TFV/FTC and by 7 days for PBMC TFV-DP/FTC-TP. Colon tissue concentrations were greater than vaginal tissue concentrations for all moieties and arms except for FTC-TP. Two weeks following the final dose: only PBMC TFV-DP was detected in blood from weekly and twice weekly arms; all drug moieties were detected in blood in most participants in the daily arm; in tissue, detection of any drug moiety was rare except for the daily regimen and in colon tissue. Steady-state weekly-dose-adjusted concentrations did not demonstrate dose-proportionality for TFV-DP and FTC-TP (ANOVA p<0.05). Steady-state daily dosing inter- and intra-subject coefficient of variation (CV%) ranged from 33% - 63% and 14% - 34%, respectively, across all drug moieties and increased with less frequent dosing.

**Conclusions:** Steady-state TFV-DP concentration was established earlier than predicted and dose-proportionality was not demonstrated in the phosphorylated moieties. Steady-state plasma TFV concentrations from daily dosing were consistent with concentrations reported in the Partners, TDF2 and Thai IDU PrEP studies (high levels of HIV protection); higher than in iPrEx (moderate protection), and far higher than in FEM-PrEP and VOICE (no protection). Therefore, HPTN 066 data can be used to benchmark adherence estimates in oral TFV PrEP trials, and assist in interpreting clinical outcomes.

Steady-state plasma TFV concentrations from daily dosing were consistent with concentrations reported in the Partners, TDF2 and Thai IDU PrEP studies (high levels of HIV protection); higher than in iPrEx (moderate protection), and far higher than in FEM-PrEP and VOICE (no protection). Therefore, HPTN 066 data can be used to benchmark adherence estimates in oral TFV PrEP trials, and assist in interpreting clinical outcomes.

**Background:** AIDS Clinical Trials Group (ACTG) Study A5279 is a phase III clinical trial (N=3000) comparing 4 weeks (wk) of daily rifapentine + isoniazid for the prevention of active TB in HIV-infected individuals. RPT is a known CYP inducer, while EFV is a CYP substrate leading to concern for decreased EFV exposure and risk of virologic failure. The pharmacokinetics (PK) of this combination have not been evaluated. An objective of A5279 was to evaluate the effect of RPT/INH on EFV PK in the first 90 participants who enrolled on a stable EFV-containing regimen.

**Methodology:** Participants receiving ART containing EFV (600mg PO QD) randomized to the weight based RPT/INH (RPT, ≈10mg/kg; INH, 300mg) treatment arm of A5279 were evaluated. Mid interval plasma samples were collected at wk 0 (pre-RPT/INH) and wks 2 and 4 during concomitant RPT/INH. EFV apparent oral clearance (CL/F) was modeled using Bayesian estimation (ADAPT). Wk 2 and 4 EFV concentrations were combined to estimate EFV CL/F on RPT/INH. EFV PK were evaluated in real time. The geometric mean ratio (GMR) and 90% confidence interval (CI) of the pre and during RPT/INH EFV CL/F values were calculated. EFV PK data were to be judged acceptable if ≥80% of participants had EFV concentrations ≥1 mg/L.

**Results:** Demographic and baseline data from the 86 evaluable participants were: female, 47 (55%); Black Non-Hispanic, 47 (55%); median age, 35y (13-61); median BMI, 23.2; 78 (93%) had undetectable HIV-1 RNA at randomization; median CD4+ count, 500 cells/mm3 (164-1570). The table gives EFV PK data. The GMR (90% CI) of EFV CL/F was 1.04 (0.98-1.11). The numbers of participants with EFV concentrations ≥ 1 mg/L were: wk 0, 84 (98%); wk 2, 80 (93%); wk 4, 77 (90%); wks 2 and 4, 74 (86%). Median (IQR) RPT concentrations were 9.18 mg/L (6.21-12.7 mg/L).

**Conclusions:** Overall, the CL/F of EFV with and without RPT/INH was equivalent, as judged by the GMR and 90% CI. A decrease in the percentage of participants with EFV concentrations \(\geq 1\) mg/L during RPT/INH therapy suggests induction of EFV CL/F, presumably from RPT. Importantly, the proportion did not cross below the pre-specified threshold of >80%. Assessments of plasma HIV-RNA levels post RPT/INH are ongoing. These drug-drug interaction data provide support that RPT/INH for 4 weeks can be co-administered with EFV-containing ART, and provide the necessary PK evidence for continuing the efficacy assessment of RPT/INH ultra-short therapy for the prevention of TB in HIV-infected individuals.

**Pharmacokinetic Variability in TB Therapy: Associations With HIV and Effect On Outcome**

1Malawi Liverpool Welcom Trust Clinical Research Programme, Blantyre, Malawi; 2University of Liverpool, Liverpool, United Kingdom; 3Liverpool School of Tropical Medicine, Liverpool, United Kingdom; 4College of Medicine, University of Malawi, Blantyre, Malawi

**Background:** Inter-individual variability in exposure to anti-tuberculous drugs is well-described during therapy. However, relationships between pharmacokinetic parameters and clinical outcomes are poorly understood, particularly in HIV-endemic regions of southern Africa. Clinical pharmacokinetic-pharmacodynamic (PK-PD) studies are required to evaluate these associations and inform the development of shorter treatment regimens.

**Methodology:** Adults with a first presentation of smear ‘++’ or ‘+++’ pulmonary TB were treated with standard 6 month therapy. HIV status, CD4 count and prior ART were documented at baseline. Plasma was sampled at 0, 2 and 6 hours post-dose on day 14 or 21 to assay concentrations of all four first-line anti-TB drugs. Mixed effects modelling of liquid culture Time to Positivity (TTP) and Serial Sputum Colony Counting (SSCC) data was used to generate individual patient estimates of the bacillary elimination rate during the first 8 weeks. Patients were followed until 1 year post-treatment and final outcomes were defined as favourable (sustained cure) or unfavourable (failure/relapse). Relationships between PK parameters and PD measurements of treatment response were assessed by logistic regression.

**Results:** 75/133 (56%) patients were HIV-infected (median CD4 count: 166 [range 6-783] cells/μl) and 24 (18%) were on ART. Although 95% patients reported excellent adherence, 98/113 (87%) had a low rifampicin Cmax, 59/118 (50%) had a low isoniazid Cmax, 46/118 (39%) had a low pyrazinamide Cmax and 24/104 (23%) had a low ethambutol Cmax compared to published reference ranges. HIV associated factors did not explain inter-individual variability in the PK parameters of any first-line drug, although there was a trend towards a lower Cmax of rifampicin amongst those who were HIV-infected (p=0.09). A low AUC0-6h of isoniazid was associated with slower bacillary clearance in TTP and SSCC models (p=0.038 and 0.040 respectively), a lower likelihood of 2 month sputum culture conversion (p=0.045) and a higher likelihood of unfavourable final outcomes (p=0.035).

**Conclusions:** The frequent finding of a low rifampicin Cmax advocates for acceleration in the conduct of rifamycin dose escalation studies in HIV-endemic populations. The association between low isoniazid exposure and all PD measures of treatment response has not been previously described and highlights the importance of clinical PK-PD studies in unravelling the determinants of early and late TB outcomes.
Oral Abstracts

phenotypes. The unique mycobacterial cell wall contains unusual, complex lipids which contribute to the permeability barrier that underlies the intrinsic antibiotic resistance of most mycobacteria. Multiple tuberculosis drugs target cell wall structures, and many known resistance genes code for enzymes in cell wall lipid pathways. Two of the newly identified genes (murD and ponA1) contribute to the biosynthesis and homeostasis of the cell wall component peptidoglycan. Functional analysis of PonA1 mutants demonstrated an in vitro growth advantage in the presence of the drug rifampicin.

Conclusions: Three of the five genes (ppsA, pks12 and pks3) participate in the biosynthesis and translocation of surface-exposed lipids. Previous work showed that MICs are reduced in pks12-deficient M. avium and that targeted pks12 deletion in BCG leads to increased ethidium bromide uptake and antibiotic sensitivity. Recently, we used an unbiased metabolomics approach to analyze a set of progressively resistant strains from a human patient who developed high level drug resistance, identifying 96 molecules whose intensity changed coincident with the acquisition of resistance. Among these was the lipid product of Pks12, which increased consistent with a gain of function phenotype.

Is Latent TB Infection Really Latent?
Petros C. Karakousis
The Johns Hopkins University School of Medicine, Baltimore, MD, United States

Background: Global tuberculosis (TB) eradication efforts are hampered by the vast reservoir of persons with latent TB infection (LTBI). Although the lifetime risk of reactivation is 5-10% among immune competent persons, HIV-infected persons have a ~10% annual risk of reactivation. For this reason, it is recommended that those with HIV infection are tested for LTBI and treated if positive. However, currently available regimens are lengthy (daily isoniazid for 9 months) or pose significant drug-drug interactions with antiretroviral therapy (rifampin for 4 months). Therefore, new strategies to treat LTBI, especially in the setting of HIV co-infection, are urgently needed. A major obstacle to this end is our limited understanding of how Mycobacterium tuberculosis (Mtb) is able to persist in the infected host for years or even decades, exhibiting tolerance to anti-TB drugs. The traditional view is that LTBI represents a paucibacillary population of non-replicating organisms with reduced metabolism, likely as an adaptive response to the unfavorable milieu within caseous granulomas. Several regulatory pathways, including the stringent response, have been implicated in bacillary growth arrest and phenotypic drug tolerance. Challenging this classical paradigm, recent studies using clinically relevant animal models have reported accumulation of Mtb mutations during LTBI, suggesting continued bacillary replication, while other studies have highlighted the importance of bacterial efflux pumps in mediating mycobacterial antibiotic tolerance.

Conclusions: LTBI does not refer to a single entity, but rather represents an array of microbiological and immunohistological findings giving rise to a clinical spectrum spanning LTBI and active TB. An improved understanding of the host-pathogen interactions underlying LTBI is expected to yield: 1) Novel potential drug targets for persistent bacilli, with the goal of shortening the duration of TB chemotherapy; 2) Novel diagnostic markers specific to the latent stage of infection and to reactivation disease; and 3) Novel attenuated vaccine candidates with an inability to reactivate, which is particularly important in the setting of HIV/AIDS.

Quantifying TB Treatment Response Using PET/CT
Clifton E. Barry III
National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Background: Definitive clinical trials of new chemotherapy for tuberculosis (TB) treatment require following subjects until at least six months after they discontinue taking medicine to assess durable cure, making these trials expensive and lengthy. Surrogate endpoints relating to treatment failure and relapse are currently limited to sputum microbiology, which is neither very sensitive nor very specific.

Conclusions: In this study we prospectively assessed radiographic changes using positron emission tomography (PET) and computed tomography (CT) at two (PET and CT) and six (CT only) months in a cohort of subjects with multidrug-resistant (MDR) TB who were treated with second-line TB therapy for two years and then followed up for an additional six months. CT scans were read semi-quantitatively by radiologists and computationally evaluated using custom software to provide volumetric assessment of TB-associated abnormalities. CT scans assessed by readers were predictive at six months but not two months and changes in computed abnormal volumes were predictive at both time points. Quantitative changes in FDG uptake two months after starting treatment were found to be highly predictive.
of long-term outcome. These radiologic markers were all more predictive than conventional sputum microbiology in distinguishing successful from unsuccessful treatment. Lesions on CT with higher radiodensity were most predictive of long-term outcome for subjects in this study. These results support the potential of radiologic biomarkers (“radiomarkers”) as possible surrogate endpoints in clinical trials of new TB drug regimens.

110 Population-Level Control of HIV-Related TB
Peter Godfrey-Fausset
Joint United Nations Programme on HIV/AIDS (UNAIDS), Geneva, Switzerland

Background: TB is still among the most common causes of death of people living with HIV (PLWH). TB remains out of control in Southern Africa where rates can be more than 1000/100,000 population per year (compared to less than 10 in some high income countries).

Conclusions: To control HIV-related TB we need social, structural and programme actions that: reduce the burden of HIV at the population level; reduce the susceptibility of PLWH to develop TB and reduce transmission of TB. Despite exciting breakthroughs in HIV prevention over the past decade, 2.3 million people were infected with HIV in 2012. Both antiretroviral therapy (ART) and isoniazid preventive therapy (IPT) reduce the risk of TB. ART also reduces the transmission of HIV. However, PLWH on ART continue to have raised rates of TB compared to the general population and the increased longevity achieved with ART expansion and the challenges in maximising and maintaining immune restoration may even increase the burden of TB over the next decades. Interrupting transmission of TB thus remains crucial. Our understanding of the HIV epidemic relies on a battery of tools that include increasingly reliable markers of recent infection as well as burden and progression of disease. In stark contrast, existing tools present a major challenge to our understanding of TB transmission dynamics. Molecular epidemiology is only available for those who progress from infection to culture positive disease. Infection assays are cumbersome, expensive, or inaccurate, and give information on cumulative infection unless individuals are followed over time. Recent studies have attempted to document contact patterns in population settings and to use markers of “shared air” as proxies for transmission risk.

The large scale community randomised trials and associated studies conducted by CREATE confirmed that IPT works well to reduce the risk of TB in the individual and, in Rio, led to benefits to the whole community of PLWH using routine services. Widescale use of IPT to both HIV-positive and -negative South African gold miners did not reduce incidence or prevalence of TB. A community based approach to enhance case-finding and treatment was inadequate to alter the epidemiology of TB in Zambian and South African communities. However, a household-based approach aimed to reduce HIV transmission, susceptibility of PLWH to TB, and TB transmission probably had a useful impact on both population level transmission of TB and prevalence of TB. Population-based control of HIV-related TB requires ongoing quality assured expansion of ART and IPT combined with greater investment in the full range of HIV prevention approaches. However it also requires refocus on TB as an infectious disease and to understand the transmission dynamics and interrupt it.

111 An Ingenious Cloak for Subterfuge: The HIV Capsid Structure
Angela M. Gronenborn
University of Pittsburgh, Pittsburgh, PA, United States

Background: HIV and other retroviruses use a Trojan horse style of infection, taking advantage of a cloak that shields its genome till the time is ripe to open the shield. Once HIV gets inside the cell, it takes over the cellular machinery, turning it into a factory for its own reproduction. This entails first to derail the normal host defense pathways, rendering HIV resistant to cell-mediated destruction responses.

Conclusions: In mature HIV-1 particles a conical-shaped capsid encloses the viral RNA genome. Previous structural analysis of two- and three-dimensional arrays provided a molecular model of the capsid protein (CA) hexamer and revealed three interfaces in the lattice. Using the high-resolution NMR structure of the CA C-terminal domain (CTD) dimer and in particular the unique interface identified, it was possible to reconstruct a model for a tubular assembly of CA protein that fit extremely well into the cryoEM density map. A novel CTD-CTD interface at the local three-fold axis in the cryoEM map was confirmed by mutagenesis to be essential for function. More recently, the cryo-EM structure of the tube was solved at 8Å resolution and this cryo-EM structure allowed unambiguous modeling and refinement by large-scale molecular dynamics (MD) simulation, resulting in all-atom models for the hexamer-of-hexamer and pentamer-of-hexamer elements of spheroidal capsids. Furthermore, the 3D structure of a native HIV-1 core was determined by cryo-electron tomography (Cryo-ET), which in combination with MD simulations permitted the construction of a realistic all-atom model for the entire capsid, based on the 3D authentic core structure.

112 Structure of a Soluble, Cleaved HIV-1 Env Trimer and Its Interaction With Broadly Neutralizing Antibodies
Ian A. Wilson
The Scripps Research Institute, La Jolla, CA, United States

Background: The discovery and isolation of highly potent, broadly neutralizing human antibodies (bnAbs) that recognize a broad diversity of HIV-1 isolates has opened up tremendous opportunities for enhancing our understanding of how HIV-1 can be neutralized. However, it has not been possible until recently to map these antibody responses onto the three-dimensional structure of the HIV-1 Envelope glycoprotein (Env), which enables viral entry into cells, as it has been extraordinarily challenging to produce stable soluble Env trimers with near native antigenicity. Such structural information is essential for rational design of HIV-1 vaccine candidates.
Conclusions: We have recently determined the x-ray structure of a soluble cleaved Env trimer that enabled greater understanding of its function in receptor binding and membrane fusion. Furthermore, mapping of the key neutralizing epitopes in the context of the Env trimer has shown that they are much larger and more complex than previously defined. Many of these antibodies have unique features that enable them to penetrate the glycan shield and bind epitopes that consist of both glycan and protein components. Using a combination of structural and biophysical techniques, we have uncovered various modes of binding and mechanisms of neutralization. Thus, elucidation of the structure and function of the Env trimer and complexes with bnAbs now provides valuable insights for structure-assisted vaccine design.

This work was done in collaboration with the labs of Andrew Ward, John Moore and Dennis Burton and was supported by NIH grants P01 AI082362 (HIVRAD), UM1 AI100663 (the Scripps Center for HIV/AIDS Vaccine Immunology and Immunogen Design (CHAVI-ID), R01 AI084817, U54 GM094586 (PSI:Biology) and the International AIDS Vaccine Initiative (IAVI).

Recognition of the HIV-1 Env trimer by glycan-dependent bnAbs as revealed by x-ray crystallography. (image created by Jean-Philippe Julien, The Scripps Research Institute)
our data further show the binding promiscuity of other dNTPs at the allosteric site. These findings suggest an intricate regulation system that may have a profound effect on the balancing of cellular dNTP pools. These results provide the basis for a mechanistic understanding of SAMHD1 function in HIV restriction, the pathogenesis of AGS, and regulation of cellular dNTP levels.

Know Your Epidemic: From Data To Action

115 Population Surveys: What Do They Show?
Peter D. Ghys
Joint United Nations Programme on HIV/AIDS (UNAIDS), Geneva, Switzerland

Background: Since 2001, a large number of national surveys with measurement of HIV status have been conducted, most of them in sub-Saharan Africa (35 countries), but also in selected countries in Asia (2 countries) and in the Caribbean (2 countries). Many of these surveys are conducted within the Demographic and Health Survey programme, others are conducted as AIDS Indicator Surveys supported by international or national organisations. Typical surveys have been limited to the 15-49 year age range for women and 15-54 or 15-59 for men.

Conclusions: Population surveys provide many advantages over traditional surveillance systems. These include that they include men as well as women, and that they are nationally representative and in recent years also designed to inform at subnational level (typically state or province). Their representative design has been critical for adjusting biases in estimated prevalence from antenatal clinic data. For example Ethiopia and the Democratic Republic of the Congo revised their national prevalence dramatically down on the basis of national surveys which showed much lower prevalence than the ANC surveillance data. The HIV prevalence information from surveys has informed epidemiological patterns used in the estimation of national epidemics, including for the sex and age pattern of prevalence, and to adjust prevalence levels from antenatal clinics in countries without survey.

Another important benefit from population-based surveys is the ability to link HIV status with socio-demographics and behaviours, allowing cross-sectional bivariate and multivariate analyses of determinants and impacts. Examples of how this has changed our understanding of HIV include the ability to map HIV prevalence to wealth status, geographic location, and behaviours.

Limitations include the possibility of biased estimates of HIV prevalence related to survey participation, their infrequent conduct (often once every 5 years), and their relatively high cost (several million USD).

Recently, the inclusion of novel laboratory methodologies is starting to enable direct estimates of HIV incidence (while validation of the optimal assay algorithms is ongoing, and confidence intervals are large) and exposure to antiretroviral treatment (ART). In the future, surveys may be also be used to assess community-based viral load and to inform the epidemiology of small geographic areas of particular interest. Expanding the age range of the sampled population, surveys can provide additional information on the HIV epidemiology among children (to date few surveys have included children) and among people over 50 years of age.

116 MSM in the UK: Prevention Effects of ART in Perspective
Andrew Phillips
University College London, London, United Kingdom

Background: Rates of new HIV infection in men who have sex with men (MSM) have in the UK and elsewhere increased in recent years, despite high levels of ART coverage and the majority of people on ART having a suppressed viral load to very low levels. It has been suggested that the beneficial effects of ART on HIV transmission have likely been counteracted by a small but significant increase in overall levels of condom-less sex in MSM in general. A further factor which needs to be considered is that a high proportion of new infections probably arise from people undiagnosed with HIV, many of whom are in primary infection. Clearly, one challenge for realization of the maximum benefits of ART in preventing transmission is to be able to diagnose people sufficiently early after infection, and ideally while in the acute stage of infection. It is not intuitively clear how high rates of HIV diagnosis and ART coverage, and how limited any increases in condom-less sex need to be, in order to bring down rates of new infections to a very low level.

The talk will mainly consist of presentation of insights into these questions from the UK MSM HIV Synthesis model, an individual-based simulation model of the epidemic in MSM in UK. The fit of the model to the UK epidemic is informed by data on sexual behaviour, HIV testing, HIV diagnoses, AIDS, death, CD4 count at diagnosis, recent infection at diagnosis, viral load and CD4 count profile of treated people, and levels of drug resistance. The model was used to reconstruct the epidemic in order to study the potential effects of future increases in HIV testing, changes in eligibility criteria for ART initiation, and changes in overall levels of condom-less sex. These results will be compared to those obtained from other MSM epidemics. Areas of uncertainty in model parameters for which additional information is required will be highlighted. These include the individual health benefits of very early ART initiation, changes in levels of condom-less sex induced by HIV diagnosis, and the effect of ART-induced viral suppression on reducing transmission through anal sex.

Conclusions: Antiretroviral treatment and condom use are both exerting a substantial limiting effect on the HIV epidemic in MSM in the UK and elsewhere and we should seek appropriate ways to maximise these effects. In particular, it is critical that the importance of condom use is continuously emphasized as a key element of prevention, with information made widely available on the specific circumstances in which risk of transmission of HIV and other infections is sufficiently low to consider lack of condom use.
117 Understanding Networks of HIV Transmission
Stéphane Helleringer
Columbia University, New York City, NY, United States

Background: HIV is transmitted through sexual or drug injection networks that connect the members of a population. The extent, structure and timing of such networks are thus important determinants of epidemic dynamics and the success of preventive interventions. In this presentation, I describe approaches to collecting network data; I provide a brief overview of the key concepts of network analysis (i.e., mapping, measuring and analyzing patterns of relationships between individuals at risk of HIV infection), and I review recent and ongoing work on HIV risks and transmission networks. In doing so, I focus on studies of heterosexual networks in HIV endemic settings of eastern and southern Africa. In such populations, networks are often characterized by a low average number of partnerships. Nonetheless, dense and decentralized networks still emerge from the formation and dissolution of multiple and possibly concurrent partnerships. Coupled with high infectivity during acute infection, these networks often expose large numbers of individuals to the risk of acquiring HIV.

Conclusions: I identify two gaps in our understanding of HIV transmission networks:
1. A narrow understanding of the complex interactions between network dynamics and the scale-up of biomedical HIV prevention;
2. Limited data on key network parameters that are not easily captured in standard sexual behavior surveys.

Finally, I describe emerging opportunities to learn about HIV transmission networks through sociocentric network studies, data routinely collected by health services during partner notification, or phylogenetic studies.

118 From Evidence To Policy: Experience From Swaziland
Velephi J. Okello
Swaziland National AIDS Programme, Mbabane, Swaziland

Background: The use of evidence to inform health policy is vital. However, generation of such evidence is frequently challenging as low and middle income countries (LMIC) are unable to fund in-country research. As a result, policies are frequently developed based on assumptions, often resulting in failure of policies to achieve desired impact on population health. However, opportunities exist to utilize available epidemiologic data as well as data generated from international settings to inform policy in LMIC. The effectiveness of evidence in informing policies relies on the capacity of the policy makers to cull available the evidence and to adapt it to real-life settings.

Conclusions: Evidence from surveillance and research studies can be utilized to identify issues for policy action and to determine types of actions. Policy makers should partner in the process of evidence generation, in prioritizing research topics and in interpretation of findings. Researchers should focus on questions relevant to key policy issues. Policy makers at the same time need to balance the many social and economic factors that influence adoption of new policies.

119 HIV-1 Infection and Type-1 Interferon
Michael H. Malim
King’s College London, London, United Kingdom

Background: The type-1 interferons (IFNs) are pro-inflammatory cytokines that are effective suppressors of HIV-1 replication, are produced at elevated levels during acute HIV-1 infection, and are associated with increased viral loads during chronic infection. This presentation will review the biology of type-1 IFN and its interplay with HIV-1 infection in humans. Drawing upon data gleaned from assorted virus infections, the following subjects will be discussed:
the pathways of IFN induction in response to infection, the mechanisms by which IFN mobilises an anti-viral state, strategies used by viruses to evade IFN-mediated inhibition, and the processes that may be affected by IFN to provoke inflammation and immunopathology.

Session PL6 Plenary
9:00 AM – 9:30 AM Auditorium

120 PEPFAR/Global Fund at 10 years: Past, Present, and Future
Stefano M. Bertozzi
University of California Berkeley School of Public Health, Berkeley, CA, United States

**Background:** The presentation will review the achievements and major lessons learned from the implementation of President’s Emergency Plan for AIDS Relief (PEPFAR) and the Global Fund to Fight AIDS, Tuberculosis and Malaria over the past ten years. It will explore in greater detail the question “are we getting our money’s worth?” and look at the evolution of the efficiency of the AIDS response in both treatment and prevention over the past decade. It will discuss areas for future improvement and options for how they might be addressed.

Session 0-9 Oral Abstracts
10:00 AM – 12:15 PM Room 312

**Interferon and Antibody at the Interface of Innate and Adaptive Immunity To HIV**

121 Cryo-EM Structures of the HIV-1 Env Trimer Reveal the Full Extent of Neutralizing Antibody Epitopes
Andrew B. Ward1, Dmitry Lyumkhis1, Natalia de Val1, Jean-Philippe Julien1, Albert Cupo2, Per Johan Klasse2, Rogier Sanders1, John Moore2, Ian Wilson1
1Integrative Structural and Computational Biology, The Scripps Research Institute, La Jolla, CA, United States, 2Weill Cornell Medical College, New York, NY, United States

**Background:** The Envelope glycoprotein (Env) on the surface of HIV-1 mediates cell entry and is the sole target for the adaptive immune system. Broadly neutralizing antibodies (bNAbs) that recognize Env and disarm HIV-1 provide hope that passive treatment or active vaccination strategies can be used to combat this disease. While X-ray crystallography has generated a molecular understanding of how bNAbs interact with Env, studies have been conducted mainly on minimal monomeric gp120 constructs or gp120 outer domain alone. Thus, these studies provide an incomplete picture of the interaction that occurs on native trimeric Env.

**Methodology:** We used cryo-electron microscopy to determine structures of the cleaved, soluble SOSIP gp140 trimer alone and in complex with bNAbs at sub-nanometer resolution. The combination of this work with additional biophysical studies of the SOSIP trimer, including isothermal titration calorimetry, reveals a detailed picture of Env recognition by bNAbs.

**Results:** The cryo-EM reconstructions illustrate the secondary structure elements of the Env trimer in relationship to various broadly neutralizing antibodies, while a 5.8 Å structure enabled building of a near complete model of the trimer. This model illustrates for the first time the relationship of the variable loops between gp120 protomers, the gp120/gp41 interface, and the fold of gp41. We find that the Env trimer is stabilized by extensive interactions between gp41, which is a three-helix bundle in the middle of the trimer, as well as inter-protomer contacts in the variable loops. Our model of the Env trimer is consistent with a wide body of Env literature and provides insights into the mechanism of receptor engagement and the conformational changes associated with viral fusion.

**Conclusions:** Our structural studies provide the first models of intact Env trimer at sub-nanometer resolution, revealing extensive details about the relative arrangement of gp120 and gp41 subunits. Our models also provide a full description of the quaternary nature of bNAb epitopes, the complexity of which were not appreciated from previous studies with monomeric gp120. The models can now be used to directly design new Env antigens for testing as HIV-1 vaccines as well as potentially improve existing bNAbs to be used for passive vaccination strategies.

122LB Immunogenicity of Cleaved, Soluble BG505 SOSIP.664 Native-Like Trimers in Rabbits
John P. Moore
Microbiology/Immunology, Weill Medical College, New York, NY, United States

**Background:** An HIV-1 Env vaccine should induce broadly neutralizing antibodies (bNAbs). One approach is to create soluble mimics of the native Env trimer that expose multiple bNAb epitopes, while occluding non-NAbs epitopes. The cleaved SOSIP.664 gp140 trimers based on the subtype A founder virus, BG505, closely approximate the desired antigenicity properties. These trimers are also highly stable and homogeneous, closely resemble native virus spikes when viewed by negative stain EM, and their high-resolution X-ray diffraction and cryoEM structures have been determined.

**Methodology:** We immunized rabbits intramuscularly with native-like BG505 SOSIP.664 gp140 trimers (or, for comparison, gp120 monomers) in ISCOMATRIX adjuvant. The trimers were produced in 293T or 293S cells and with or without glycosidase digestion. We measured the autologous and heterologous NAb responses in the sera using the Tzm.bl cell assay, and assessed NAb epitope specificities using mutant viruses and specific competitors such as Env proteins and peptides.

**Results:** The trimers induced strong (titers of 50-3000) and consistent (16 of 16 animals) NABs against the autologous, neutralization-resistant (Tier-2) BG505.T332N virus, much more so than the corresponding monomeric gp120. Heterologous Tier-1 NABs were also induced efficiently, but other Tier-2 viruses were neutralized only weakly and inconsistently. The autologous NAB responses in the trimer-immunized rabbits were similar in magnitude to those found in the HIV-1 BG505 infected-infant, but over time the infant developed broader, heterologous responses not seen in the rabbits. The most
Identification of a New Neutralization Target at the N262/N448 Glycosylation Sites On HIV-1 gp120

Xueling Wu1, Tongqing Zhou1, Helin S. Georgiev2, Sijy O'Dell3, Mark Louder4, Dennis R. Burton5, Wayne C. Koff6, Mark Markowitz7, Peter D. Kwong8, John R. Mascola3

1Aaron Diamond AIDS Research Center, New York, NY, United States, 2Vutara Inc., Salt Lake City, UT, United States

Background: Currently isolated broadly neutralizing antibodies (bnAbs) against HIV-1 demonstrate unusual genetic features such as restricted immunoglobulin (ig)-gene usage, unusual CDR3 lengths and extremely high levels of somatic hypermutation, imposing potential elicitation barriers. Alternatively, it may be beneficial to induce anti-viral antibodies by balancing the feasibility for elicitation and the requirements for anti-viral function, as suggested by the recent findings from the RV144 trial that certain gp120-binding antibodies correlate with reduced infection risk.

Methodology: Using the resurfaced stabilized gp120 core protein, RSC3, to preserve and expose the site for CD4 attachment, we previously identified VRC01 and its class of anti-HIV-1 bnAbs targeting the CD4-binding site (CD4bs) of gp120. Taking the advantage of the fact that RSC3 also preserves the surface glycans on gp120, we used RSC3 to probe IgG+ memory B-cells to identify monoclonal antibodies (mAbs) that may target glycans on gp120.

Results: From a RSC3-probed B-cell sort, we identified the VRC01-class mAbs VRC-PG04 and VRC-PG04b from the IAVI protocol G participant #74. Additionally, we identified a new mAb VRC-PG05 from the same donor and the same B-cell sort. VRC-PG05 by itself neutralized 29% of 178 tested Env-pseudoviruses; when combined with VRC-PG04, it complemented VRC-PG04 to enhance neutralization coverage and potency. The atomic-level structure of VRC-PG05 do not appear to be unusual in the human antibody repertoire, and its levels of somatic hypermutation are moderate, only 1/3 of those of VRC01 and VRC-PG04. We used a VRC-PG05 highly-sensitive strain, AC10.29, to derive monomeric gp120 recombinant proteins with point mutations to screen plasmas from 85 HIV-1 seroconverters. Using gp120 mutants lacking a glycan at either N262 or N448, we identified 17 (20%) with characteristics of VRC-PG05 do not appear to be unusual in the human antibody repertoire, and its levels of somatic hypermutation are moderate, only 1/3 of those of VRC01 and VRC-PG04. We used a VRC-PG05 highly-sensitive strain, AC10.29, to derive monomeric gp120 recombinant proteins with point mutations to screen plasmas from 85 HIV-1 seroconverters. Using gp120 mutants lacking a glycan at either N262 or N448, we identified 17 (20%) with antibodies targeted to the N262/N448 glycan-specificity. In comparison, using the D368R gp120 mutant, we identified only 2 (2%) with antibodies directed to the CD4bs.

Conclusions: Our results suggest that in HIV-1-infected individuals, antibodies targeting the N262/N448 glycan-specificity are more prevalent than those to the CD4bs. This property, along with the ability for co-elicitation with the CD4bs-directed VRC01-class and the moderate somatic hypermutation of VRC-PG05, renders this antibody specificity a new and attractive target for HIV-1 envelope-based immunogen design.

CD169 Mediates HIV-1 Evasion From Detection by α-gp120 Neutralizing Antibodies in Dendritic Cells

Hisashi Akiyama1, Nora G. P. Rainier2, Manasa Gudhe3, Suryaram Gummuru4

1Microbiology, Boston University School of Medicine, Boston, MA, United States, 2Vutara Inc., Salt Lake City, UT, United States

Background: A hallmark of chronic HIV-1 infection is constitutive immune activation associated with elevated serum levels of proinflammatory cytokines, mainly induced by microbial translocation across the gut mucosa. We have previously demonstrated that dendritic cells (DCs) matured in the presence of interferon-α (IFNα) neutralize HIV-1 through CD169+ compartments not only preserves virus infectivity but also provides evasion from detection and neutralization by CD4+ T cells. In this study we tested the hypothesis that CD169-mediated HIV-1 capture and retention in unique non-lysosomal compartments was accessible to surface-applied α-gp120 bNAbs.

Methodology: To characterize HIV-1+ compartments in mature DCs, CD14+ monocyte-derived DCs, stimulated with IFNα or LPS, up-regulate a myeloid cell-specific receptor CD169 or Siglec1, the predominant DC receptor responsible for HIV-1 capture and transfer to CD4+ T cells. Our previous results have also demonstrated the relative inability of α-gp120 broadly neutralizing antibodies (bNAbs) to inhibit mature DC-mediated HIV-1 transmission to CD4+ T cells. In this study we tested the hypothesis that CD169-mediated HIV-1 capture and retention in unique non-lysosomal compartments not only preserves virus infectivity but also provides evasion from detection and neutralization by α-gp120 bNAbs.

Results: IFNα and LPS stimulation of DCs greatly enhanced CD169 expression and HIV-1 trans-infection of CD4+ T cells. Super-resolution microscopy revealed intimate association of CD169 with HIV-1 in DCs, forming densely packed HIV-1+ clusters within surface-exposed plasma membrane invaginations, some of which are at a depth of up to 1μm from the cell surface, especially in LPS-matured DCs. Interestingly, virus particles in these compartments were inaccessible to surface-applied α-gp120 bNAbs in the absence of membrane permeabilization. Moreover, CD169+ DC-mediated HIV-1 trans-infection to CD4+ T cells was significantly more resistant to neutralization by VRC01, but not to a small molecular weight inhibitor, sCD4-183, compared to that observed with cell-free infection, suggesting that virus particles retained in surface-exposed CD169+ compartments in DCs are protected from detection by α-gp120 bNAbs.
Conclusions: These results suggest that capture of HIV-1 by CD169 in DCs not only results in trafficking and retention of virus particles in non-degradative compartments but can also provide HIV evasion from humoral responses. Since serum IFNα and LPS levels are elevated in patients chronically infected with HIV-1, this CD169-dependent evasion mechanism may contribute to HIV-1 persistence in vivo.

125 Tetherin Antagonism by Vpu Protects HIV-Infected Cells From ADCC
Juan F. Arias1, Lisa N. Heyer1, Benjamin von Bredow1, Kim L. Weisgrau1, Brian Moldt2, Dennis R. Burton3, Eva G. Rakasz2, David T. Evans1

Background: HIV-1 Vpu facilitates virus replication by downmodulating at least three different cellular proteins: Tetherin (BST-2 or CD317), a restriction factor that interferes with the detachment of nascent virions from infected cells, CD4, the primary receptor for virus entry, and NTB-A, a co-stimulatory molecule required for natural killer (NK) cell activation. While the mechanisms of these Vpu activities have been studied in detail, their role in immune evasion is not well understood.

Methodology: Using an assay recently developed in our laboratory to measure the ability of antibodies to direct the killing of HIV-infected cells by antibody-dependent cell-mediated cytotoxicity (ADCC), we compared the effects of IFNα treatment, mutations that differentially affect functional activities of Vpu, and RNAi-knocking down of tetherin, CD4 and NTB-A, on the susceptibility of HIV-infected cells to Env-specific antibodies.

Results: Treatment with increasing concentrations of IFNα resulted in a dose-dependent increase in the susceptibility of HIV-infected cells to ADCC, which corresponded to a dose-dependent increase in cell-surface expression of tetherin, but not NTB-A or CD4. Mutations in Vpu that specifically impair tetherin antagonism, without affecting CD4- or NTB-A-downmodulation, increased the susceptibility of HIV-infected cells to ADCC. Conversely, RNAi-knockdown of tetherin, but not NTB-A or CD4, decreased the susceptibility of virus-infected cells to ADCC.

Conclusions: Our results reveal that Vpu protects HIV-infected cells from ADCC as a function of its ability to counteract restriction by tetherin. These observations suggest that by preventing the accumulation of nascent virions on the cell surface, the anti-tetherin activity of Vpu reduces the exposure of HIV-infected cells to antibodies that might otherwise result in their elimination by antibody-dependent immune responses. By serving as link between innate and adaptive immunity, the antiviral activity of tetherin may be augmented by virus-specific antibodies, and hence much greater than previously appreciated based solely on its ability to inhibit virus replication in cell culture assays.

126 HIV Nef and Vpu Protect HIV-infected CD4+ T Cells From ADCC Through Downmodulation of CD4 and BST2
Tram N. O. Pham1, Sabelo Lukhele1, Fadi Hajjar1, Jonathan Richard1, Rajesh M. Valanparambil2, Halima Medjahed3, Mathieu Coutu3, Andres Finzi3, 4, Eric A. Cohen1, 4

Background: HIV accessory proteins like Nef and Vpu are capable of modulating host proteins such as CD4 and BST2 to evade ultimately host’s immune defenses. Indeed, the CD4 receptor is down-regulated by Nef, and to a lesser extent, by Vpu and envelope (Env). BST2 retains new virions at the cell surface restricting their release; and this action is antagonized by Vpu via BST2 downregulation. In recent years, Fc-mediated effector functions including antibody-dependent cell-mediated cytotoxicity (ADCC) have been increasingly recognized as a potentially powerful host response against HIV. Latest evidence has suggested that the epitopes that are recognized by ADCC-potent anti-HIV antibodies (Abs) (e.g., A32) are transiently exposed upon CD4-Env interaction, the first step of the HIV entry. Thus, we hypothesized that by down-modulating CD4 and BST2 expression at the cell surface, Nef and Vpu could protect HIV-infected CD4+ T cells from ADCC by alleviating exposure of Env epitopes targeted by ADCC-competent Abs.

Methodology: Primary and CEM.NKR CD4+ T cells were infected with CCR5-tropic GFP-marked HIV-1 NL4.3 ADA virus or derivatives lacking Nef (N-), Vpu (U-) or both (N-U-), and examined by FACS for Env expression using anti-Env Abs including A32 and broadly-neutralizing 2G12. Infected cells were evaluated for their susceptibility to ADCC (FACS-based assay) by peripheral blood mononuclear cells (PBMC) using A32 and 2G12 as model Abs.

Results: A32 staining was consistently, markedly highest on CD4+ T cells infected with N-U- virus compared to those infected with the other viruses. The enhanced recognition of the A32, but not of the 2G12, epitope was intimately dependent on cell-surface CD4 expression, and correlated with heightened ADCC activity. CD4-Env interaction was required for this process since the use of the N-U- Env D368A mutant, which blocks CD4-Env engagement, significantly reduced the magnitude of A32 staining and ADCC. Depletion of BST2 from target cells abolished the residual ADCC activity observed with the N-U- Env D368A mutant. Both natural killer cells and monocytes/macrophages within the PBMC population were found to contribute to cell lysis by ADCC.

Conclusions: Our findings strongly suggest that CD4 and Env interaction during virus gene expression induces conformational changes on the Env such that ADCC-competent anti-HIV Abs can bind to their epitopes on infected CD4+ T cells and mark them for lysis by immune cells. By cross-linking nascent virions at the plasma membrane, and hence, increasing the Env density at the cell surface, BST2 further enhances the efficiency of this process. Collectively, our data unveil a potential molecular mechanism by which HIV Nef and Vpu function synergistically to spare infected T cells from ADCC and promote viral persistence.
Identification of HIV-infected CD4+ T Cells Using HIV RNA and Broadly Neutralizing Antibodies

Joseph P. Casazza1, Alexander C. Vostal1, Irene R. Primmer1, David R. Ambrozak1, Amarendra Pegu2, Eli Boritz3, Mark K. Louder3, Daniel C. Douek3, John R. Mascola1, Richard A. Koup1

1Immunology Laboratory, NIAID, Bethesda, MD, United States, 2Virology Laboratory, NIAID, Bethesda, MD, United States, 3Human Immunology Section, NIAID, Bethesda, MD, United States

Background: HIV envelope proteins are expressed on the surface of HIV-infected CD4 T cells prior to and during viral budding. The manufacture of multiple broadly neutralizing antibodies has raised the possibility of using these biologics as immunotherapeutic agents in chronic HIV infection. We have used these agents and real time PCR of HIV RNAs to identify individual HIV-infected cells.

Methodology: In vitro BAL infected CD4 T cells were used to screen MPER, V1V2, V3 glycan and CD4bs antibodies for their ability to identify HIV-infected cells. HIV-infection was confirmed by either p24 staining, or quantitation of spliced Tat- and Rev-associated RNA and Gag RNA. Anti-envelope antibodies capable of identifying in vitro infected CD4 T cells were identified for V1V2, V3 glycan and CD4bs antibodies. To detect HIV-expressing cells ex vivo, live CD8 T cells from individuals not on antiretroviral therapy were sorted into CD4 bright, dim and null populations and the frequency of cells actively transcribing HIV RNA determined using limiting dilution analysis. Individual cells from the CD4 dim population that did or did not stain with anti-env antibodies were index sorted and characterized with respect to maturational and activation phenotype.

Results: Surface staining with PG9, PGT121 and VRC07 easily identified live, in vitro HIV-infected CD4 T cells. CD4 T cells positively stained for env proteins actively transcribed HIV RNA and produced p24. Ex vivo, the greatest number of T cells actively transcribing HIV RNA was found in the CD4 bright population, but the highest frequency of cells transcribing HIV RNA was found in the dim population. Median intracellular copy number of HIV RNAs was significantly higher in the CD4 dim population than in the CD4 bright population; in some individuals the frequency of cells actively transcribing viral RNA approached 2%. The frequency of CD4 null cells was so low that we could not accurately measure this value in most subjects. Down-regulation of surface expression of CD4 in individual cells actively transcribing HIV RNA ex vivo was rarely more than one log, whereas down regulation of CD4 surface expression in vitro was often greater than 2 logs. Ex vivo surface staining of env proteins by PG9, PGT121 and VRC 07 was marginal with no clear population of env staining cells identified in the dim population.

Conclusions: Env staining is less bright ex vivo than in in vitro infected CD4 T cells and should make the targeting of HIV-infected CD4 T cells by monoclonal antibodies more difficult ex vivo than in vitro. Nonetheless the identification of individual HIV-infected cells ex vivo is important for targeted elimination strategies.

Type I Interferon Signaling Is Critical for Early Control of Immune System Damage

Netanya G. Sandler4, Steven E. Bosinger5, Jacob D. Este4, Eli Boritz2, Brandon F. Kea2, Jerome A. Langer2, Jeffrey D. Lifson3, Srini S. Rao1, Gideon Schreiber6, Daniel C. Douek4

Background: Whether type I IFN (IFN-I) is beneficial in HIV infection by inducing antiviral genes or detrimental by driving immune activation is controversial. IFN receptor antagonist (IFN-1ant) treatment during acute SIV infection accelerated progression to AIDS and death. Its mechanism and the consequences of exogenous IFN-I treatment during acute infection are unknown.

Methodology: 6 rhesus macaques (RMs) received IFN-1ant and 9 RMs placebo starting at challenge through 4 weeks post-infection (wpi). 6 RMs received pegylated IFNα2a weekly from 1 week before challenge through 4 wpi and 3 RMs IFNα2b but no challenge. All challenges were done with high dose rectal SIVmac251. We evaluated SIV+ cells by in situ hybridization, APOBEC3G and TRIM5α by immunohistochemistry (IHC), lymphocyte activation and responses by flow cytometry and transcriptional profiles by mRNA deep sequencing (mRNAseq). P-values were calculated by Kaplan-Meier survival curves and differences between groups by the Mann-Whitney U test.

Results: IFN-1ant RMs had delayed and reduced upregulation of IFN-stimulated genes (ISGs, see figure) and lower lymph node (LN) levels of the IFN-inducible restriction factors APOBEC3G and TRIM5α compared to placebo. They had more SIV+ cells in their LN at 12 wpi and greater LN CCR5+ CD4 T cell depletion at 4 (P=0.02) and 12 wpi (P=0.03). IFN-1ant RMs had decreased frequencies of LN HLA-DR+ CD4 (P=0.009) and CD8 (P=0.02) T cells and peripheral blood (PB) CD16+ NK cells (P=0.01) but not SIV-specific CD4 or CD8 T cells at >12 wpi. IFNα2a RMs required more challenges to be infected than placebo (P=0.0002) and had fewer transmitted/founder variants (P=0.04). After infection, IFNα2a RMs had lower peak ISG
levels, more PBMC-associated SIV gag DNA at 10, 14 and 28 dpi (P=0.04, 0.04, 0.002) and greater LN CCR5+ CD4 T cell depletion at 4 (P=0.02) and 12 wpi (P=0.03). PB CD16+ NK cells (P=0.03) but not SIV-specific T cells were decreased in IFNα2a RMs at >12 wpi. SAMHD1, TRIM22 and TRIM5 expression were transiently increased in PBMCs and rectal biopsies from unchallenged RMs treated with IFNα2a.

Conclusions: Delayed and decreased ISG expression during acute SIV infection in IFN-1ant RMs resulted in increased LN virus burden and CD4 T cell depletion, suggesting that IFN-α is critical for early control of immune system damage. While increased IFN signaling can stimulate antiviral genes and protect against infection, it may result in less ISG upregulation after infection and accelerated disease progression.

129 miR-422a: A Solitary MicroRNA Biomarker of Interferon-α Anti-HIV-1 Activity In Vivo
Mohamed Abdel-Mohsen1, Xutao Deng1, Teri Liegler1, Andri Rauch1, Bruno Ledergerber2, Huldrych F. Günthard3, Joseph K. Wong4, Satish K. Pillai1, 2
1Medicine, University of California, San Francisco, San Francisco, CA, United States, 2Blood Systems Research Institute, San Francisco, CA, United States, 3Infectious Diseases, Bern University Hospital and University of Bern, Bern, Switzerland, 4Infectious Diseases and Hospital Epidemiology, University Hospital Zurich, University of Zurich, Zurich, Switzerland, Division of Infectious Diseases and Hospital Epidemiology, University Hospital Zurich, University of Zurich, Zurich, Switzerland, 5Medicine, San Francisco Veterans Affairs Medical Center, San Francisco, San Francisco, CA, United States

Background: The cytokine interferon-α (IFN-α) potently suppresses HIV-1 in vitro and in vivo. IFN-α therapy was also recently associated with significant reduction in the size of the HIV-1 latent reservoir. We hypothesized that microRNAs (miRNAs) contribute to the IFN-α-mediated suppression of HIV-1.

To inform the development of novel miRNA-based antiretroviral strategies, we investigated the effects of exogenous IFN-α treatment on global miRNA expression profile, HIV-1 viremia, and potential regulatory networks between miRNAs and cell-intrinsic anti-HIV-1 host factors in vivo.

Methodology: Longitudinal PBMC samples were obtained from seven HIV/HCV-coinfected, ART-naïve individuals enrolled in the Swiss HIV Cohort Study before, during, and after pegylated interferon-α/ribavirin therapy (IFN-α/riba). The expression of 754 cellular miRNAs, the Drosha, Dicer1 and DGR8 miRNA machinery genes, and 34 anti-HIV-1 restriction factors was measured in PBMC using real-time PCR. False discovery rates (FDR) were calculated to account for multiple comparisons in statistical analyses. We identified potential regulatory networks between miRNAs and restriction factors by analyzing inverse expression relationships and sequence homology between miRNA seed sequences and restriction factor mRNA 3′-UTRs.

Results: IFN-α/riba decreased HIV-1 viral load by 0.80 (±0.33) log10 copies/ml. Of all 754 miRNAs measured, only one miRNA, miR-422a, was significantly modulated by IFN-α/riba in vivo (p<0.0001, paired t test; FDR<0.037). miR-422a log fold-reduction was significantly correlated with HIV-1 log viral load reduction during IFN-α/riba (r2 = 0.72; p<0.015). IFN-α/riba did not significantly affect expression levels of miRNA machinery genes. Out of 62 inverse-correlated miRNA-miRNA pairs, 38 exhibited significant sequence homology between miRNA and restriction factor mRNA. This frequency (38/62) was significantly higher than the background (8455/25636), estimated by examining random miRNA-mRNA pairs (p = 8.0*10e-6, odds ratio = 3.2 [C.I. = 1.9 to 5.6], Fisher’s exact test). In particular, miR-422a exhibited potential regulatory relationships with TRIM19, TRIM22, HERC5, and IFITM3.

Conclusions: Our data suggest that the specific suppression of miR-422a contributes to the anti-HIV-1 capacity of IFN-α in vivo, possibly via regulation of multiple retroviral restriction factors. Taken within the context of recent clinical trials demonstrating the effectiveness of miRNA targeting to treat HCV infection, miR-422a may represent a promising pharmacological target to treat or eradicate HIV-1 infection. Moreover, our regulatory network analysis presents additional candidate miRNAs that may be targeted to enhance anti-HIV-1 restriction factor expression in vivo.

130 Increased Arterial Inflammation Relates to High-Risk Coronary Plaque Morphology in HIV+ Patients
Ahmed Tawakol1, Markella V. Zanni1, Janet Lo2, Ezinne J. Ihenachor2, Allison Han1, Megan MacNabb1, Bryan Wai1, Udo Hoffmann1, Suhny Abbara2, Steven Grinspoon2

Background: CVD is increased in HIV, but specific mechanisms remain unknown. Among HIV+ patients, independent studies demonstrate increased arterial inflammation (by 18F-FDG-PET) and increased high risk morphology (HRM) coronary atherosclerotic plaque (by coronary CT angiography, CTA). However, the critical interrelationship between these features in HIV+ patients has not been assessed. We hypothesized that arterial inflammation and HRM coronary plaque would be closely related when simultaneously assessed among HIV+ patients.

Methodology: 41 HIV+ patients on stable ART without a history of CVD but found to have coronary plaque on coronary CTA were evaluated with 18F-FDG-PET. HIV+ patients were stratified into two groups based on relative degree of arterial inflammation (aortic TBR) on PET. High risk coronary atherosclerotic plaque morphology features (low attenuation plaque and positive remodeling) - along with demographic/CVD risk/HIV-specific parameters - were compared between the groups with relatively higher and lower arterial inflammation.

Results: The HIV+ patients with higher and lower TBR’s were similar with respect to traditional CVD risk factors and HIV-specific parameters such as duration of HIV, ART use, and viral load. Among HIV+ patients with higher TBR, there was an increased percentage of patients with at least one low attenuation coronary atherosclerotic plaque (40% vs. 10%, p=0.02) and one coronary atherosclerotic plaque characterized by both low attenuation and positive remodeling (35% vs. 10%, p=0.04). Moreover, in the higher TBR group, both the number of low attenuation plaques/subject (p=0.02) and the number of high risk features in the most high risk plaque (p=0.02) were increased. In multivariate modeling among the entire HIV+ group,
Arterial Inflammation in HIV as Measured by FDG-PET/CT Is Associated With Splenic Activity

Priscilla Y. Hsue1, Megan Machnabb, Rebecca Kaplan1, Elaine Nitta1, Steven Deeks2, Jeffrey Martin1, Miguel Pampaloni1, Peter Ganz2, Ahmed Tawakol2

1Cardiology, University of California San Francisco, San Francisco, CA, United States, 2Massachusetts General Hospital, Boston, MA, United States

Background: HIV-infected individuals have increased arterial inflammation and higher risk of cardiovascular disease (CVD), likely related to chronic monocyte/macrophage (MΦ) activation. Arterial inflammation as assessed by 18fluorodeoxyglucose (FDG) PET/CT correlates with MΦ activity and is predictive of CVD risk. Since MΦ that participate in atherosclerosis originate in the bone marrow and transiently reside in the spleen, we sought to evaluate the relationship between arterial inflammation and bone marrow and spleen activity in HIV using FDG-PET/CT.

Methodology: 20 HIV-infected men and 20 non-infected controls (matched for age, gender and Framingham Risk Score) were studied. For the HIV group, 11 (55%) were treated and had an undetectable HIV viral load, and 9 were untreated (45%). Individuals underwent PET-CT imaging and FDG uptake was quantified as standardized uptake values, (SUV) in the bone marrow, spleen, wall of the ascending aorta, and control tissues (muscle and subcutaneous fat). For between-subject comparisons, SUV was corrected for blood background (SUVc).

Results: The mean age (±SEM) of the participants was 54±2. Arterial inflammation was higher among HIV infected individuals vs. controls (SUV: 3.07±0.17 vs. 2.05±0.06, p<0.001). Similarly SUVc in both the bone marrow and spleen were higher among in HIV (2.87±0.28 vs 1.73±0.07 p=0.002 and 2.10±0.20 vs 1.56±0.05 p=0.006, respectively). Aortic SUV was strongly related to splenic SUV (r= 0.69, p<0.001, Figure 1) and bone marrow SUV (r=0.62, p<0.001) but was not associated with SUV of muscle (r=0.26, p=0.11) or fat (r=0.24, p=0.20).

Conclusions: We demonstrate that arterial inflammation is increased in HIV-infected individuals and is significantly associated with bone marrow and splenic activity. In contrast, FDG-uptake in control tissues does not correlate with arterial inflammation. Thus, upregulation of immune cell activity in the bone marrow and splenic reservoir may contribute to arterial inflammation in the setting of HIV infection.

Replicative Senescence of Circulating Osteogenic Cells and Low BMD in Perinatally Infected Men

John S. Manavalan, Stephen Arapdi, Jayesh Shah, Chiyuan A. Zhang, Marc Foca, Natalie Neu,斯塔罗乌拉·科乌斯提，Michael T. Yin

Columbia University Medical Center, New York, NY, United States

Background: We have previously demonstrated that men infected with HIV early in life have 6-19% lower volumetric bone mineral density (vBMD), markedly abnormal trabecular plate and cortical microarchitecture, and decreased whole bone stiffness by High Resolution peripheral Quantitative CT (HRpQCT) of the radius and tibia. We hypothesize that early HIV infection is associated with accelerated replicative senescence and exhaustion of the cellular proliferative capacity of bone cell precursors, which negatively impacts bone formation.

Methodology: A cross-sectional study was performed in 30 HIV-infected men on stable ART and 15 HIV-uninfected men aged 20-25 years utilizing HRpQCT and flow cytometry to identify circulating osteogenic cells in peripheral blood mononuclear cells (PBMCs). Among HIV-infected men, 15 were perinatally-infected (PNI) and 15 were infected during adolescence (ADI). Runx2, osteocalcin (OCN) and CD34 antibodies, were used to identify specific osteogenic cell populations in lineage (LIN) negative PBMCs enriched for stem and progenitor cells. Our previous studies suggest that OCN+CD34+ cells are more mature osteogenic cells than OCN+CD34+ cells, since they have lost the hematopoietic CD34 marker and express higher mRNA levels of Runx2, and alkaline phosphatase. Relative average telomere length was measured in sorted osteogenic cells (LIN-/OCN+/Runx2+) using qPCR, and expressed as the relative ratio of telomere (T) to nuclear DNA (S) copies.

Results: Percentage of circulating osteogenic cells (LIN-/OCN+/Runx2+) in PBMCs was lower in both the PNI group (0.15+/-0.10%) and the ADI group (0.22+/-0.12%) than in uninfected controls (0.39+/-0.26%; p<0.05); but did not differ between HIV-infected groups. In contrast, the PNI group had a significantly lower percentage of mature osteogenic cells (LIN-/OCN+/Runx2+/CD34+; 55.6+/-27.3%) than both the ADI group (73.2+/-11.4%; p<0.05) and uninfected controls (67.2+/-6.8%; p<0.05). Similarly, the PNI group had shorter telomere lengths (T/S ratio: 2.3+/-0.2) in LIN-/OCN+ cells than both
the ADI group (T/S ratio: 2.5+/-0.2; p<0.05) and uninfected controls (T/S ratio: 2.6+/-0.4; p<0.05). Percentage of OCN+RUNX2+ cells correlated with total vBMD at the radius (r=0.442, p=0.005), as well as cortical and trabecular vBMD, and cortical and trabecular thickness; but not with tibial HRpQCT parameters.

Conclusions: These data suggest that HIV infection early in life, especially perinatal infection, is associated with replicative senescence and decreased numbers and maturation of circulating osteogenic cells, which may result in decreased number and function of osteoblasts and contribute to reductions in BMD and microarchitectural deficiencies.

133 High-Dose Vitamin D and Calcium Attenuates Bone Loss With ART Initiation: Results From ACTG A5280

Edgar T. Overton1, Ellen S. Char2, Todd T. Brown3, Pablo Tebas4, Grace A. McComsey5, Kathleen M. Melbourne6, Andrew Napoli7, Royce Hardin8, Heather J. Ribaudo9, Michael T. Yin9, ACTG A5280 Study Team

1University of Alabama School of Medicine, Birmingham, AL, United States, 2Harvard School of Public Health, Boston, MA, United States, 3The Johns Hopkins University, Baltimore, MD, United States, 4Hospital of the University of Pennsylvania, Philadelphia, PA, United States, 5Pediatrics, Case Western Reserve University, Cleveland, OH, United States, 6Gilead Sciences, Foster City, CA, United States, 7Virology, Bristol-Myers Squibb, Plainsboro, NJ, United States, 8Duke University Community Advisory Board, Durham, NC, United States, 9Harvard School of Public Health, New York, NY, United States

Background: Low bone mineral density (BMD) is common among HIV-infected persons, and the initiation of ART (particularly tenofovir-containing regimens) is associated with 2-5% loss in BMD. Vitamin D deficiency is common among HIV-infected and uninfected individuals; further, efavirenz decreases vitamin D levels. Vitamin D and calcium supplementation have well-described beneficial effects on bone health.

Methodology: This 48-week prospective, randomized, double-blind, placebo-controlled study evaluated the effect of high dose vitamin D3 (4000 IU daily) plus calcium supplementation (1000 mg calcium carbonate daily) on BMD in HIV-infected subjects initiating ART with efavirenz/emtricitabine/tenofovir. The primary endpoint was percentage change in total hip BMD over 48 weeks. Group comparisons by intent-to-treat analysis (ITT) used exact Wilcoxon rank sum tests stratified by screening 25(OH) vitamin D level.

Results: Of 165 eligible subjects enrolled (79 Vitamin D/calcium (Vit D/Cal); 86 placebo), 142 subjects had evaluable DXA data at baseline and week 48 and were included in ITT analysis. The study arms were well-balanced, including reported dietary calcium and vitamin D intake (813 mg and 131 IU daily, respectively). The population was 90% male; 37% non-Hispanic white, 33% non-Hispanic black, 25% Hispanic. Median age was 33 years, BMI 24.4 kg/m2, CD4 count 341 cells/mm3, HIV-1 RNA level 4.5 log10 copies/mL, and 25(OH) vitamin D 23 ng/mL. Vitamin D/calcium supplementation was well tolerated; only 3 subjects discontinued due to toxicities (1 vit D/cal, 2 placebo); grade 3 or 4 events were reported in 22% in Vit D/cal arm and 23% in placebo arm. At week 48, 90% of subjects had HIV-1 RNA < 50 copies/mL. Subjects receiving vitamin D/calcium supplementation had less decline in total hip BMD (median: -1.46%; 1st-3rd quartile (Q1, Q3): -3.16%, -0.40%) than placebo (-3.19%; -5.12%, -1.02%) (p=0.001). BMD loss at lumbar spine was similarly reduced with vitamin D/calcium supplementation (-1.41%; -3.78%, 0.00% vs. -2.91; -4.84%, -1.06%) but failed to achieve statistical significance (p=0.085).

Conclusions: Vitamin D/calcium supplementation mitigated the loss of BMD seen with initiation of efavirenz/emtricitabine/tenofovir, particularly at the total hip, which is the site of greatest concern for fragility fracture. Future research will evaluate the potential of this safe, low-cost preventive measure to attenuate bone loss associated with other ART regimens.

134 Rosuvastatin Improves Hip Bone Mineral Density But Worsens Insulin Resistance

Grace A. McComsey1, Ying Jiang1, Kristine M. Erlanson2, Sara M. Debanne1

1Case Western Reserve University, Cleveland, OH, United States, 2University of Colorado Anschutz Medical Campus, Aurora, CO, United States

Background: The effect of statin therapy on bone mineral density (BMD) in HIV-infected subjects on antiretroviral therapy (ART) is unknown. Also, there are conflicting reports on statin increasing the risk of diabetes in HIV-infected subjects.

Methodology: The 96-week Stopping Atherosclerosis and Treating Unhealthy bone with RosuvastatiN in HIV (SATURN-HIV) trial is a randomized, double-blind, placebo-controlled trial to evaluate the effect of statins on markers of cardiovascular risk and skeletal health in HIV. Subjects were ≥ 18 years, on stable ART, with HIV-1 RNA <1000 copies/mL, LDL-cholesterol <130 mg/dL and evidence of immune activation (defined as having CD8+CD38+HLA-DR+ >19% and/or hsCRP >2 mg/L). Subjects were randomized 1:1 to daily rosuvastatin 10 mg or matching placebo, and stratified by protease inhibitor use and presence/absence of osteopenia (t score at lumbar spine or total hip < -1). The primary bone endpoint was DEXA-measured changes in total hip BMD. Primary analyses were intent-to-treat. Statistical tests included multivariable linear regression.
**Results:** 147 subjects enrolled; 78% male, 70% blacks. Median age was 47 years and CD4 count 613 cells/µL; 49% were on PI therapy with median ART and PI duration of 64 and 42 months, respectively; 89% were on TDF; 23% were osteopenic at the hip and 22% at the spine; 78% had HIV-1 RNA <50 copies/mL. Study arms were well balanced. At week 48, statin therapy was associated with a significant increase in total hip BMD (mean ± SD 0.6% ± 2.3%) vs. a decrease in placebo (-0.6% ± 2.9%); p=0.017. Changes in trochanter BMD was also significantly better with statin (0.9% increase vs. 0.7% decrease in placebo; p=0.042). Changes in spine BMD were similar between treatment groups (p=0.66). In addition to the significant statin effect, larger increases in hip BMD were independently and significantly associated with lower baseline soluble tumor necrosis factor-receptor I (sTNFR-I), but not other inflammation markers, and greater 96-week increases in BMI and sTNFR-I (but not other inflammation markers). Within the statin group, the mean (SD) percent increases from baseline in insulin and HOMA-IR were 52% (116%) and 72% (173%), respectively (differences between groups p<0.01 for both). One subject (in placebo group) with entry fasting glucose of 87 mg/dL developed overt diabetes at week 48.

**Conclusions:** Rosuvastatin therapy increased total hip and trochanter BMD in HIV-infected subjects on ART, regardless of baseline bone density and concomitant PI therapy. Markers of insulin resistance worsened significantly after statin therapy. Follow up to 96 weeks is continuing and will assess the longer term changes in these endpoints.

**Effects of Tesamorelin On Hepatic Fat in HIV Patients: A Randomized, Placebo-Controlled Trial**

**Takara Stanley,** Meghan Feldpausch, Jinhee Oh, Karen Branch, Martin Torriani, Steven Grinspoon  
Massachusetts General Hospital, Boston, MA, United States

**Background:** Hepatic fat is often increased in HIV-infected patients with abdominal fat accumulation and may contribute to metabolic abnormalities. Currently, no strategies exist to reduce fat in this critical depot among HIV-infected patients. Tesamorelin, a growth hormone releasing hormone analogue, is FDA-approved for reduction of visceral fat in HIV, but its effects on hepatic fat are unknown. The purpose of this study was to investigate the effects of tesamorelin on hepatic fat in HIV patients. In addition, we investigated novel effects on other fat depots, detailed measures of insulin sensitivity, and cardiovascular risk markers, including carotid intima-media thickness (cIMT).

**Methodology:** Fifty antiretroviral-treated HIV-infected men and women with abdominal fat accumulation (waist > 95 cm and waist:hip > 0.94 for men; waist > 94 cm and waist:hip > 0.88 for women) were randomized to receive tesamorelin 2mg vs. placebo SC daily for 6 months. Primary endpoints were change in liver fat as measured by magnetic resonance spectroscopy and change in visceral adipose tissue (VAT) as measured by computed tomography. Secondary endpoints included intramyocellular lipid (IMCL), measures of glucose and insulin sensitivity, and cIMT.

**Results:** Tesamorelin significantly reduced VAT over 6 months (Δ -34±9 vs. 8±11 cm², P = 0.005) and hepatic lipid (Δ -2.0 [-6.4, 0.1] vs. 0.9 [-0.6, 3.7] lipid-to-water %, median [IQR], P = 0.004, tesamorelin vs. placebo) over 6 months, yielding a median 40% decrease in baseline liver fat in the treated group. Reduction in VAT was significantly associated with decrease in liver fat (p = 0.31, P = 0.047). Trunk fat also decreased (-0.4 [-1.4, 0.7] vs. 0.6 [0.1, 1.7] kg, tesamorelin vs. placebo, P = 0.01), whereas subcutaneous adipose tissue (SAT) and IMCL did not significantly change between groups. Fasting glucose increased in the tesamorelin group at 2 weeks (change from baseline 9 ± 10 vs. 2 ± 12 mg/dL, tesamorelin vs. placebo, P = 0.03), but changes in fasting and 2 hour glucose and fasting insulin at 3 and 6 months were not significantly different between tesamorelin and placebo. By euglycemic hyperinsulinemic clamp, insulin-stimulated glucose disposal, a measure of insulin sensitivity, worsened after 3 months but returned to baseline after 6 months. cIMT decreased by 4% over 6 months within the tesamorelin group (-0.03 ± 0.02, P = 0.04) but did not change in the placebo group (0.00 ± 0.02, P = 0.89) (between group P-value = 0.15). IGF-I increased as expected in the tesamorelin group vs. placebo (P<0.001).

**Conclusions:** Tesamorelin significantly reduces hepatic fat in association with VAT reduction among HIV-infected patients with abdominal fat accumulation with no significant changes in glucose homeostasis after 6 months of treatment.

**Early Treatment in Acute SIV Infection Limits the Size and Distribution of the Viral Reservoir**

Afam A. Okoye1, Mukta Rohankhedkar1, Matthew Reyes1, Joseph Clock1, Derrick Duell1, Yoshinori Fukazawa1, Richard Lum1, Haesun Park1, Jeffrey D. Lifson1, Louis J. Picker1  
1Vaccine & Gene Therapy Institute and the Oregon National Primate Research Center, Oregon Health & Science University, Beaverton, OR, United States, 2Frederick National Laboratory for Cancer Research, SAIC-Frederick, Inc, Frederick, MD, United States

**Background:** Recent reports suggest that early treatment intervention during primary HIV infection has a profound impact on the viral reservoir. Indeed, the case of the Mississippi baby and the VISCONTI cohort suggests that reservoirs established early during acute HIV replication may be quantitatively and qualitatively different from reservoirs established later in chronic infection and perhaps be more amenable to cure. Here we sought to investigate the effect of early treatment on the viral reservoir in SIV-infected rhesus macaques (RM) when antiretroviral therapy (ART) is initiated either prior to peak viral replication, at or near peak viral replication, or in early chronic infection.

**Methodology:** To test the effect of timing of treatment on viral reservoir, RM infected intravenously with SIVmac239 were subjected to multi-drug ART consisting of tenofovir, emtricitabine, dolutegravir and darunavir boosted with ritonavir starting day 7 (group A), day 10 (group B) or day 42 (group C) post-challenge. Plasma viral loads (pVL) and cell-associated viral loads of peripheral blood mononucleocytes (PBMC), bone marrow (BM), small intestinal mucosa (GUT) and lymph node (LN) biopsy samples were assessed by real-time quantitative PCR/RT-PCR at various time points.

**Results:** In group A (n=2), pVL continued to rise after therapy was initiated, peaking by day 12 to an average of 71000 SIV RNA copies/ml then declined below the limit of detection (<30 copies/ml) after just 6 weeks of ART. In group B (n=2), pVL peaked on day 12 to an average of 1.8x10^6 copies/ml and
required 18 weeks of ART to decline below the limit of detection. In group C (n=18), peak pvl was reached between days 12-14 to an average of 1.4x10^7 copies/ml but complete virus suppression was not achieved in all RM even after 20 weeks of ART. SIV DNA per 10e6 PBMC were on average 1020, 8606, 43914 copies in groups A, B and C, respectively, at 17 weeks post-challenge and a combined analysis showed there was a significant correlation between peak plasma SIV RNA and the levels of total SIV DNA in PBMC (p=0.03). In addition, SIV DNA in LN, BM and GUT were lower, on average 497, 1929 and 324 copies/10e6 cells, respectively, in group A, compared with an average of 9647, 4069 and 35090 copies/10e6 cells, respectively, in group B 17 weeks post-challenge.

Conclusions: These results demonstrate that early ART, when initiated prior to peak virus replication, limits systemic virus dissemination and seeding of the reservoir in peripheral and extra lymphoid mucosal compartments. A delay as short as three days during the “hyperacute” phase can result in over a log higher tissue-based reservoir size, once therapy is started and maintained. Aggressive monitoring for acute infection with immediate introduction of ART could profoundly influence treatment outcomes.

137 CD4 T-Cell Subset Composition of HIV Reservoirs in Gut, Lymph Node, and Blood During HAART

Steven A. Yukl1, 2, Teri Liegler1, Mohamed Abdel-Mohsen1, Elizabeth Sinclair1, Hiroyu Hatano1, Frederick Hecht1, Ma Somisouk1, Sarah Palmer1, 4, Steven G. Deeks1, Joseph K. Wong1, 2

1University of California San Francisco, San Francisco, CA, United States, 2Seattle Children’s Hospital, Seattle, WA, United States, 3Fred Hutchinson Cancer Research Center, Seattle, WA, United States, 4Karolinska Institute, Stockholm, Sweden, 5Westmead Millennium Institute for Medical Research, Sydney, Australia

Background: Central and transitional memory CD4 T cell maturation subsets comprise the largest fraction of the HIV reservoir in peripheral blood but less is known about the cellular composition of HIV reservoirs in those lymphoid tissues that disproportionately harbor HIV during suppressive ART.

Methodology: 8 subjects on ART (5 started treatment during chronic infection, 3 during early infection, ART duration >3years, VL<50c/ml, CD4>350) underwent leukapheresis, lymph node biopsy and rectal biopsy. Following cell isolation, flow-based sorting was used to isolate naïve (Nv), central- (CM), transitional- (TM) and effector- (EM) memory populations. Cellular HIV DNA and RNA were measured using previously published real time PCR assays and were normalized by simultaneous measurement of TERT and GAPDH, respectively. Infection frequencies and HIV expression was compared among sites and T cell subsets.

Results: HIV DNA was measurable from a majority of CD4 T cell maturation subsets from all three sites. The highest HIV DNA concentrations were in EM cells in rectum (median 2289 [IQR 1269-6424] c/10^8, p=0.008 for comparison with concentrations in EM, TM and CM from blood). HIV DNA levels in TM/CM cells in rectum were also higher than in CM or TM (p=0.016) and EM (p=0.16) in blood. HIV+ cell concentrations were intermediate for T cell subsets in lymph node. As expected, Nv cells had low infection frequencies. Paradoxically, HIV expression per infected cell (expressed as ratio of HIV RNA to DNA) was lower in all subsets in rectum compared to blood; expression levels were intermediate in lymph node cells. The contribution of each T cell subset to the total HIV reservoir differed strikingly by site. Infected EM comprised 80% of the total T cell reservoir in rectum, 40% of the reservoir in lymph node but <20% in blood. With the caveat of a small study size, infection frequencies tended to be lower in early treatment subjects compared to chronic treatment subjects while the distribution of infection among T cell subsets were not appreciably different between subject groups.

Conclusions: The distribution of the reservoir is tissue dependent, with rectal tissues notable for a high frequency of HIV DNA in EM cells, but low levels of HIV RNA expression in these and other memory cells. The majority of the infected cells in rectum and ai sizable minority of infected cells in lymph node are found in EM cells, while most of the infected cells in blood are in CM/TM cells. These data suggest that the local host environment affects HIV expression and how latently infected cells take up residence. The impact of potentially curative interventions on HIV persistence is expected to be different across anatomic sites.

138 Proliferation of Cells With HIV Integrated Into Regulatory Genes Is a Mechanism of Persistence

Thor A. Wagner1, 2, Sherry McLaughlin1, 2, Kavita Garg3, Hannah Huang3, Sheila Strychak1, James I. Mullins1, Lisa M. Frenkel1, 2

1University of Washington, Seattle, WA, United States, 2Seattle Children’s Hospital, Seattle, WA, United States, 3Fred Hutchinson Cancer Research Center, Seattle, WA, United States

Background: Understanding the mechanisms of HIV persistence during ART is important for developing curative strategies. Our previous work suggests that proliferation of HIV-infected cells helps sustain the HIV DNA reservoir during ART. To confirm that HIV-infected cells proliferate and investigate how specific HIV-infected cells persist during suppressive ART, viral integration sites and the associated envelope sequences were determined.

Methodology: PBMC DNA from participants on long-term suppressive ART was diluted to a single HIV template per PCR. The chromosomal integration site and the associated HIV env (C2-V5) was sequenced. Integration sites were identified with BLAST. For integration sites located within a gene, the biological function of the gene (gene ontology) and statistical enrichment of genes associated with defined biological processes was evaluated with Bioconductor.

Results: 538 integration sites were determined following single-template PCR of DNA diluted from 9 specimens from 3 participants after ~2, ~6, and ~10 years of suppressive ART. Multiple identical HIV integration sites were detected within each individual; these replicates accounted for 39.6% (213/538) of integration sites. Linked HIV env sequences were amplified from 68 integration sites. All env sequences amplified from the same integration site (32 env sequences from 13 integration sites) were identical, whereas only one env sequence was shared between 37 different integration sites (Fischer’s exact, 13/13 vs 1/37, P<0.0001), a distribution consistent with infected cell proliferation. 372 different integration sites were identified, of which 63.7% (237/372) were located in genes. The integration site recovered most frequently (32 times) was in MDC1, which has a known role in cell cycle arrest and apoptosis.

These results demonstrate that proliferation of HIV-infected cells persist during suppressive ART. Increased viral integration sites and the associated envelope sequences were determined.
cell cycle, such as cell activation, differentiation, and proliferation. These results strongly suggest that the specific gene disrupted by HIV integration may impact cellular proliferation and survival.

Conclusions: A disproportionate number of integrations at identical sites in the human chromosome spanning many years and linked to identical HIV env sequences indicates that proliferation of infected cell contributes to the persistence of HIV cellular reservoirs. Furthermore, HIV integration into specific sites in the human chromosome may modify gene function, allowing proliferation and prolonged persistence of specific infected cells.

139 Novel Ex Vivo Approaches Distinguish Effective and Ineffective Drugs for Reversing Latency In Vivo
Gregory M. Laird, C. Korin Bulleen, Janet D. Siliciano, Robert F. Siliciano
The Johns Hopkins University School of Medicine, Baltimore, MD, United States

Background: HIV-1 persists in a latent reservoir (LR) despite antiretroviral therapy (ART). This reservoir is the major barrier to HIV-1 eradication. Current approaches to purge the LR involve pharmacologic induction of HIV-1 transcription and subsequent killing of infected cells by cytolytic T lymphocytes or viral cytopathic effects. Agents that reverse latency without activating T cells have been identified using in vitro models of latency, however their effects on latently infected cells from infected individuals remain largely unknown.

Methodology: We evaluated the effects of candidate latency reversing agents (LRAs) on resting CD4+ T cells (rCD4s) from HIV-1 infected patients on suppressive ART. Disulfiram, JQ1, bryostatin-1 and the HDAC inhibitors vorinostat, romidepsin, and panobinostat were tested at clinically relevant concentrations that effectively reversed latency in a primary cell in vitro model. Two novel independent assays were developed for ex vivo evaluation of the leading candidate LRAs. We first tested LRAs for their ability to induce viral outgrowth from latently infected patient cells. Next, we evaluated the ability of LRAs to induce increases in intracellular HIV-1 mRNA in patient rCD4s.

Results: We treated purified rCD4s from patients on ART with individual LRAs for 18 hours and then cultured them with MOLT-4/CCR5 cells for 14 days to allow viral outgrowth. Surprisingly, none of the LRAs induced viral outgrowth from cells from any patient tested. Vorinostat, romidepsin, panobinostat, disulfiram, and JQ1 all failed to increase intracellular HIV-1 mRNA in patient rCD4s after 18 hours treatment. Only the PKC agonist bryostatin-1 caused significant increases, though the effect was only seen in some patients. Similar results were observed after 6 hours of LRA treatment. While a previous study reported modest increases in transcripts containing HIV-1 gag sequence in patient rCD4s after ex vivo and in vivo vorinostat treatment (Archin et al., Nature 2012), we show that such small increases are likely a result of host promoter initiated read-through transcription of the integrated HIV-1 provirus.

Conclusions: The novel assays presented herein facilitated the first comparative ex vivo evaluation of candidate LRAs. None of the candidate non-T cell activating LRAs tested disrupted the LR ex vivo. The striking discordance between the effects of non-T cell activating LRAs in models of HIV-1 latency and the ex vivo effects we observed in rCD4s from patients on ART indicates that these in vitro models do not fully capture all mechanisms governing HIV-1 latency in vivo. We conclude that these compounds are unlikely to drive the elimination of the LR in vivo when administered individually, as has been proposed.

140 Effect of Vorinostat On Host Gene Expression in HIV Infected Patients On Antiretroviral Therapy
Khader Gnineim1, Jeff Atlhers1, Julian Elliott1, Miranda Smith1, Fiona Whitehorn1, Ajantha Solomon1, Miles Prince2, Steven Deeks3, Rafick Sekaly2, Sharon Lewin2
1VGTI-FL, Port Saint Lucie, FL, United States, 2Department of Infectious Diseases, Monash University, Melbourne, Australia, 3Department of Medicine, University of California, San Francisco, CA, United States

Background: Histone deacetylase inhibitors (HDACi) activate HIV production in latently infected T-cells in vitro. Recently, the HDACi vorinostat was shown to significantly increase cell associated unspliced (CA-US) HIV RNA in HIV infected subjects on suppressive antiretroviral therapy (ART). However, the effects of vorinostat on host gene regulation and the relationship of these changes to efficacy in activation of HIV transcription is unknown. The main aim of this study was to determine the effects of multi-dose vorinostat on host gene expression in HIV infected patients on ART.

Methodology: We evaluated differential gene expression in blood from 20 HIV infected patients on ART who received vorinostat (400mg/day) for 14 days. Gene expression was analyzed at baseline and two time points on vorinostat (d1 and d14) and post-cessation of vorinostat (d84). Differential gene expression was assessed using a (moderated) t test. For data mining and functional analyses, the genes selected satisfied a false discovery rate (FDR) corrected p-value ≤ 0.05.

Results: There was clear difference in gene expression for all patients at d1, d14 and d84 compared to baseline. At d1, there was a distinct pattern of response in 7/20 patients with marked up-regulation of genes and enrichment of pathways involved in transcription, chromatin remodeling, translation elongation and cell survival. We could also observe the selective upregulation of genes involved in the regulation of HIV latency including CDK9, HEXIM2 and RELA. Transcriptional activity associated with chromatin remodeling disappeared by day 14 in all patients but there was persisting differential gene expression at day 14 and day 84 compared to baseline. At day 14, the major differentially expressed genes were associated with reduction of oxidative stress/inflammation and genes associated with DNA repair. At day 84, the major differentially expressed genes were alpha defensins. Regression analysis of gene expression and CA-US HIV RNA revealed distinct transcriptomic profiles correlating with high and low levels of CA-US HIV RNA at day 1.

Conclusions: These results suggest that the effects of vorinostat on chromatin largely occur within the 1st day after the first dose of drug and that after 14 days of continuous dosing, there are compensatory mechanisms associated with transcriptional repression and cell survival. These results will guide future interventions testing SAHA’s capacity to purge the HIV reservoir.
141 Cyclophosphamide Enhances SB-728-T Engraftment To Levels Associated With HIV-RNA Control

Gary Blick1, Jay Lalezari2, Ricky Hsu3, Edwin DeJesus4, Trevor Hawkins2, Ronald Mitsuya6, Steven Deeks2, Gary Lee2, Winson Tang3, Dale Ando5
1Circle Care Center, Norwalk, CT, United States; 2Quest Clinical Research, San Francisco, CA, United States; 3Private Practice, New York, NY, United States; 4Orlando Immunology Center, Orlando, FL, United States; 5Southwest Care, Santa Fe, NM, United States; 6UCDAVID Geffen School of Medicine, Los Angeles, CA, United States; 7UCSF School of Medicine, San Francisco, CA, United States; 8Sangamo BiSciences, Richmond, CA, United States

Background: SB-728-T is a zinc finger nuclease-mediated, CCR5-modified autologous CD4 T-cell product that can provide a reservoir of CD4 T-cells that are resistant to HIV entry. Studies in ART-treated CCR5Δ32 heterozygote HIV subjects showed VL reductions from peak during treatment interruption that correlated with estimated circulating bi-allelic CCR5-modified CD4 T-cells (maximal at ~200 cells/μL), supporting the importance of achieving this level of transferred T-cells. We have now evaluated cyclophosphamide (CTX) conditioning prior to infusion of SB-728-T in HIV subjects. CTX enhances the engraftment and activity of adoptively transferred anti-cancer T-cells by homeostatic proliferation of the transferred T-cells, an increase in endogenous cytokines (e.g. IL-7 and IL-15) and promotion of homing to lymphoid organs.

Methodology: A dose escalation study of IV CTX, 200 mg (n=3); 500 mg/m² (n=6) and 1 g/m² (n=3) administered 1-3 days prior to SB-728-T infusion was performed in aviremic, ART treated HIV subjects with CD4 T cell counts > 500.

Results: CTX was well tolerated at all doses, except for low grade GI side-effects which were treated with anti-emetics. No clinically significant decreases in neutrophils, WBC, platelets or Hgb/Hct were seen. A dose-related increase in total CD4 count and engraftment of CCR5 modified cells was observed (median estimated bi-allelic modified CD4 cells and median increase in total CD4 at six weeks post infusion of 14/μL and 299/μL at 200 mg, 74/μL and 771/μL at 500 mg/m² and 148/μL and 2077/μL at 1 g/m², respectively). By comparison, total CD8 cell count at wk 6 was not affected by the CTX dose administered (median of 783/μL at 200mg, 536/μL at 500 mg/m² and 679/μL at 1 g/m²). Engraftment of estimated bi-allelic CCR5 modified CD4 cells with the 1 g/m² CTX dose was near levels associated with anti-viral effects in CCR5Δ32 heterozygote HIV subjects. A 1.1 to 1.5-log VL reduction from peak was seen in 2 subjects at the 500mg/m² dose level and in another subject at the 1 gram/m² dose level during a 16 week TI. The latter subject had an increase of CD4 T-cells of 3496 cells /μL at wk 1, and estimated bi-allelic modified CD4 T-cells of 148 cells/μL at six weeks post infusion with VL reduction from 235K to 79 K (VL set pt 35,500).

Conclusions: CTX pre-treatment is well tolerated up to 1 g/m² in ART treated HIV subjects with no adverse effects on hematologic parameters. A dose-related increase in engraftment of SB-728 T-cells occurred to levels obtained in CCR5Δ32 heterozygote HIV subjects who have achieved unmeasurable VL during TI. CTX conditioning may be a useful strategy to 1) maximize the engraftment and anti-viral effects of SB-728-T adoptive T cell therapy in HIV subjects and 2) may be an important immunomodulatory chemotherapeutic agent for immunotherapy in HIV.

142 Stimulation of Subdominant CTL Response Is Required for the Elimination of HIV-1 Latent Reservoir

Kai Deng, Mihaela Pertea, Liang Shan, Robert Siliciano
The Johns Hopkins University, Baltimore, MD, United States

Background: HAART can control viral replication in HIV-1 infected individuals, but can’t eliminate the virus due to viral persistence in latent reservoirs. Eradication strategies have focused on reactivation of latent HIV-1 in the reservoir without global T cell activation. Our recent study suggested reactivation of latent HIV-1 alone might not be enough, and stimulation of HIV-1-specific CTL response facilitated clearance of the latent reservoir. However, plasma HIV-1 develops CTL escape mutations to evade immune response. CTL escape of HIV-1 has been studied extensively through the analysis of plasma virus, but little is known regarding the potential presence of CTL escape variants in the latent reservoir. This raises a critical issue for CTL-based eradication strategies: if CTL escape variants are archived in the latent reservoir, the host CTL response may fail to recognize and clear infected cells after latency is reversed.

Methodology: Proviral DNA from HAART-treated patients was extracted, Gag was amplified by PCR and deep-sequenced in search for CTL escape mutations. Latent HIV-1 was recovered from patients’ resting CD4+ T cells using a viral outgrowth assay. Gag from the outgrown viruses was sequenced and compared with the proviruses. Outgrown viruses were used to infect CD4+ T cells from the same patients. Autologous pre-stimulated or non-stimulated CD8+ T cells were cocultured with infected CD4+ T cells to access killing.

Results: CTL escape variants dominate in the latent reservoirs of chronic phrase-treated patients, but not in acute phase-treated patients. After reactivation, outgrown viruses still carried the same CTL escape variations with provirus in the reservoir. CD4+ T cells infected by these escape variants were insensitive to the relevant epitope-specific CTL clones, but can be killed by broad spectrum CTL response. More importantly, we were able to identify and stimulate subdominant CTL clones in chronically infected patients which can recognize and kill autologous target cells infected with these escape variants.

Conclusions: Our study demonstrates that the dominant presence of CTL-resistant viruses in the latent reservoir poses great hurdles to the viral eradication. Boosting broad spectrum or more specifically, subdominant CTL responses is required for the elimination of viral latent reservoir.

143 Dendritic Cell-Based HIV Therapeutic Vaccine Increases Residual Viremia in Individuals On ART

Bernard J. Macatangay1, Mariam B. Lawani2, Sharon A. Ridder3, Nicole D. Wheeler2, Margaret A. Bedison2, Charles R. Rinaldo2, John W. Mellors3
1University of Pittsburgh School of Medicine, Pittsburgh, PA, United States; 2Infectious Disease and Microbiology, University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA, United States

Background: We evaluated the impact of therapeutic vaccination with an autologous dendritic cell (DC) vaccine pulsed with autologous, inactivated HIV-1-infected apoptotic cells on the level of residual plasma viremia in individuals on suppressive antiretroviral therapy (ART) and following analytic treatment interruption (ATI).
Methodology: Autologous HIV-1 was obtained from 10 ART-naive subjects prior to starting ART. The vaccine was composed of monocyte-derived DCs (matured with TNFα, IL-1β, IFNγ, Poly I:C) pulsed with apoptotic cells generated from autologous lymphocytes infected with autologous HIV-1. After at least 12 weeks of virologic suppression, subjects received 3 doses of vaccine (10^10 DC/dose, 2 weeks apart). Six weeks after the third vaccination, subjects underwent ATI with a 4th vaccine dose given 2 weeks into ATI. Plasma samples from Pre-ART, 3 time points pre-ATI, and 2 and 4 weeks post-ATI were assayed for residual viremia by single copy assay targeting HIV-1 integrase (SCA). PBMCs were obtained at baseline and right before ATI to evaluate levels of immune activation (HLA-DR+CD38+) and regulatory T cell (Treg) frequencies (CD4+CD25+Foxp3+).

Results: After at least 8 weeks of HIV RNA suppression <50 cps/ml (Roche Amplicor v1.5), 6/9 subjects had residual viremia detected by SCA ranging from 2.0-49.5 cps/mL. In 10/10 subjects, levels of residual viremia increased 2.9- to 41.8-fold (mean=14-fold) after vaccination and before ATI despite the continuous ART. CD4+ and CD8+ T cell activation increased after the 1st vaccine dose but returned to pre-vaccine levels before ATI, whereas residual viremia in the 4 subjects continued to increase. There was no correlation between residual plasma viremia and activation of CD4+ (r=-0.44; p=0.23) or CD8+ cells (r=-0.30; p=0.41). Treg frequencies did not change and did not correlate with levels of residual viremia. Two weeks after ATI, 8 subjects were undetectable by the Roche assay, but 6 of 8 had detectable viremia by SCA (range=19.9 to 3322 cps/mL; median=145.9 cps/mL). Plasma viremia measured by both assays rebounded to pre-ART levels by week 6 of ATI in 7/10 subjects.

Conclusions: Vaccination with an autologous DC-HIV vaccine did not prevent viral rebound after ATI and increased residual viremia in 40% of subjects despite continuous ART. The increase in residual viremia was not associated with changes in T cell activation or Treg frequency. Therapeutic vaccination may increase HIV-1 replication or expression from latent reservoirs.

144LB HIV-1 Rebound Following Allogeneic Stem Cell Transplantation and Treatment Interruption
Timothy J. Henrich1, Emily Hanhausen2, Michael N. Sirignano3, Jonathan Z. Li4, Mathias Lichterfeld5, Francisco M. Marty6, Philippe Armand7, Robert J. Soiffer8, Marcus Attelev9, Daniel R. Kritzes1
1Brigham and Women’s Hospital, Harvard Medical School, Cambridge, MA, United States, 2Brigham and Women’s Hospital, Cambridge, MA, United States, 3Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, 4Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States, 5Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, 6Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, United States

Background: We reported the loss of detectable HIV-1 reservoirs in 2 individuals following reduced-intensity conditioning allogeneic hematopoietic stem cell transplantation (HSCT) from HLA wild-type donors. HIV-1 remained undetectable from blood and rectal tissue on ART despite the testing of large numbers of PBMCs or CD4+ T cells in the setting of full donor chimerism. As a result, analytical treatment interruption (ATI) was performed, and we now provide an in-depth analysis of HIV-1 viral/immune dynamics during ATI and after viral rebound.

Methodology: ATI was performed in consenting patients with weekly to biweekly monitoring of viral load (VL) and proviral DNA by clinical assays. Large-volume blood draws, leukapheresis, and cerebral spinal fluid sampling was performed before, during and/or after ATI to perform: 1) quantification of HIV-1 DNA in PBMCs and in sorted CD4+ T lymphocyte subsets (central memory, effector memory, stem cell memory, terminally differentiated, and naive cells), 2) plasma RNA quantification by single copy assay (SCA), 3) characterization of HIV-specific T cell immunity and viral rebound and decay following ART re-initiation, and 4) single-genome analysis of full-length HIV-1 env sequences from DNA prior to HSCT and post-rebound plasma RNA.

Results: During ATI, patient A had no detectable plasma RNA or cell-associated HIV-1 DNA for 3 months and patient B had no detectable virus for 8 months after ART cessation prior to eventual rebound. Patient B also had negative PBMC DNA (<0.07 copies/10^6 PBMCs) and viral RNA by SCA (<0.4 copies/mL) by ultrasensitive assays 5 and 18 weeks into ATI. Once detected, plasma RNA increased rapidly, reaching 2-4x10^6 copies/ml within 2-3 weeks; rebound plasma viremia was mono/oligophyletic. Both patients developed symptoms of acute retroviral syndrome, including aspetic meningitis and new NNRTI resistance in one patient that developed early after ART-initiation. Symptoms rapidly resolved with initiation of active ART and subsequent viral suppression in both patients. Patient A had detectable but low-level HIV-1 DNA in pre-ATI terminally differentiated lymphocytes isolated from 200x10^6 PBMCs from post-hoc testing after rebound, but from no other subsets; patient B had no detectable HIV-1 DNA.

Conclusions: Our results suggest that allogeneic HSCT may lead to loss of detectable HIV-1 from blood and gut tissue, but viral rebound can occur despite up to a 3-4 log10 reduction in reservoir size. Long-lived tissue reservoirs, including host macrophages that may be replaced more slowly than T-lymphocytes following HSCT may have contributed to viral rebound. More sensitive assays for detecting HIV persistence are needed; ATI remains the most reliable measure of viral persistence following therapeutic intervention.

Antiretroviral Scale-Up in Sub-Saharan Africa: Challenges and Opportunities

145 Age-Disparate Relationships and HIV Incidence Amongst Rural South Africa Women
Guy Harling1, Marie-Louise Newell1,2, Frank Tanser1, Ichiro Kawachi4, SV Subramanian4, Till Bārnhagens1,2
1Global Health and Population, Harvard School of Public Health, Boston, MA, United States, 2University of Southampton, Southampton, United Kingdom, 3Africa Centre for Health and Population Studies, Mtubatuba, South Africa, 4Social and Behavioral Sciences, Harvard School of Public Health, Boston, MA, United States

Background: Age-disparate relationships are considered risky for young women due to older men having higher levels of both incident and prevalent HIV, and more social and economic power to coerce women into riskier sex. Both these effects are likely to be weaker for older women. Several public health campaigns have been run to discourage young women from relationships with older men. However, longitudinal evidence relating sex-partner age-disparity on HIV acquisition is lacking.
Methodology: We analyzed a population-based cohort of women in rural KwaZulu-Natal, South Africa who were HIV seronegative at first interview between January 2003 and June 2012. We stratified our cohort by age into younger (15-29 years; n=2,444) and older (30-50 years; n=1,737). Using proportional hazards models, we measured whether the age-disparity of a woman’s most recent sexual partner at each annual round of HIV testing was associated with subsequent HIV acquisition.

Results: Amongst younger women, 458 HIV seroconversions occurred over 5,913 person-years of follow-up (incidence rate [IR]: 7.75 per 100 person-years). The age-disparity of women’s partners was not associated with HIV acquisition when measured either continuously (hazard ratio [HR] for a one-year increase in partner’s age: 1.00, 95% confidence interval [CI]: 0.97-1.03) or categorically (man ≥5 years older: HR 0.98, 95%CI 0.81-1.20; man ≥10 years older: HR 0.98, 95%CI 0.67-1.43).

Amongst older women, 116 seroconversions occurred in 5,714 person-years of follow-up (IR: 2.03 per 100 person-years). As partner age rose, HIV incidence risk fell significantly: a five-year older partner was associated with a one-third reduction (HR: 0.63, 95%CI: 0.52-0.76) and a ten-year older partner with a one-half reduction (HR: 0.48, 95%CI: 0.35-0.67), compared to a same-aged partner.

Results for both age groups were robust to adjustment for known socio-demographic and behavioural HIV risk factors, and did not vary significantly by women’s age, marital status, education attainment, or household wealth. Associations did not vary significantly by woman’s age within each age-group.

Conclusions: In this rural KwaZulu-Natal setting with very high HIV incidence, older partner age did not predict HIV acquisition amongst young women, and appeared protective for older women. Campaigns to reduce age-disparate sexual relationships may not be a cost-effective use of HIV-prevention resources for the young, and may be inappropriate or even harmful for older women.

One Year Outcomes Following Community-Based HIV Self-Testing: A Prospective Study in Malawi
Augustine T. Choko1, Peter MacPherson2, 3, Emily L. Webb1, Helena Ball1, Rodrick Sambakunsi1, Aaron Mido2, Simon D. Makombe4, Nicola Desmond1, 2, Richard Hayes1, Elizabeth L. Corbett1, 3
1Malawi Liverpool Wellcome Trust Clinical Research Programme, Blantyre, Malawi, 2Liverpool School of Tropical Medicine, Liverpool, United Kingdom, 3London School of Hygiene & Tropical Medicine, London, United Kingdom, 4HIV Unit, Ministry of Health, Lilongwe, Malawi

Background: HIV testing and counselling (HTC) is key to care and prevention, but only ~25% of adults in sub-Saharan Africa report testing for HIV in the preceding 12 months. HIV self-testing (HIVST) is a novel approach that could promote increased coverage and frequency of HTC. We investigated HIVST including subsequent linkage into care.

Methodology: 16,660 adult (≥16 years) residents of 14 high-density neighbourhoods (HIV prevalence 18.5%) were included in a cluster randomised trial. Two residents were trained in each neighbourhood to provide HIVST from their homes (one test per resident per year). Clients received written and verbal information to promote linkage into HIV care coupled with home-initiation of HIV care if requested. Population-level uptake was estimated from enumeration denominators. Accuracy of HIVST was assessed through quality assurance (QA) re-testing (2 parallel rapid tests) with a 10% random sample of self-testing.
clients asked to retest. A strong community-based reporting system was in place for monitoring adverse events. Data were analysed using summary statistics and logistic regression adjusted for clustering.

**Results:** Overall, 13,966 self-test kits were distributed with 89% returned as used kits with feedback forms. Uptake was 76% (12,658/16,660), including 5,846 (67%) of all men. The highest uptake was in the youngest age group (16-19 years: 2,360/2,539, 93%) falling to 41% (298/733) in men ≥50 years. Early HIVST adopters (2,658 in 1st month) were significantly more likely to be female, adjusted odds ratio (aOR) 1.20 (95% CI 1.06-1.36); younger Ptrend<0.001, and not in a couple aOR 2.22 (95% CI 1.54-3.16). In total, 851/16,660 (9%) residents confirmed positive HIVST results with 25% already on ART and 500/638 (78%) accessing HIV care (pre-ART or ART). QA showed 99.1% agreement with self-reported HIVST results (sensitivity 93.8% [95% CI 85.0-98.3%], specificity 100% [95% CI 100-100%]). No suicides or assaults were reported, but coercion was reported by 147 (3.7%) and 119 (2.2%) female respondents; p-value<0.001, mostly from partners.

**Conclusions:** Uptake of HIVST, subsequent linkage into care, and accuracy were high with this strategy. Uptake of HIVST, subsequent linkage into care, and accuracy were high with this strategy. Coercive testing and retesting on ART are concerning aspects of HIVST that need to be anticipated and discouraged. Community-based HIVST offers high potential to increase knowledge of HIV status, assisting with increasing access to HIV care and prevention when combined with proactive linkage strategies. Community-based HIVST offers high potential to increase knowledge of HIV status, assisting with increasing access to HIV care and prevention when combined with proactive linkage strategies.

**148 Community HIV Testing and Linkage To Care Reduces Population Viral Load in South Africa and Uganda**

Ruanne V. Barnabas1,2, Heidi van Rooyen1, Elioda Tumwesigye4, Melgham Krown1, Pam Murnane1, Hilton Humphries1, Bosco Turyamureeba1, James P. Hughes2,5, Jared Baeten6, Connie Celem5

1Global Health and Medicine, University of Washington, Seattle, WA, United States, 2Fred Hutchinson Cancer Research Center, Seattle, WA, United States, 3HIV/AIDS, STIs and Tuberculosis (HAST) Programme, Human Sciences Research Council, Sweetwaters, South Africa, 4Integrated Community Based Initiatives, Kabwohe, Uganda, 5Global Health and Epidemiology, University of Washington, Seattle, WA, United States, 6Global Health, Epidemiology and Medicine, University of Washington, Seattle, WA, United States

**Background:** High coverage of HIV counseling and testing (HCT) through community campaigns and linkage of HIV+ people to care has the potential to decrease HIV incidence if most eligible people initiate antiretroviral therapy (ART) and are virally suppressed.

**Methodology:** We conducted community-wide home-based HCT in KwaZulu-Natal, South Africa, and Mbarara, Uganda, from September 2011 to May 2013. Resident adults within a geographically defined community were offered HCT. HIV+ persons received point-of-care CD4 results (PIMA), counseling about HIV and ART, referral for HIV care, and follow-up visits at months 1, 3, 6, 9 and 12. HIV viral load was measured among all (N=570) HIV+ persons at baseline, 6 and 12 months.

**Results:** 3,546 adults from 1,549 households were enrolled and 636 HIV+ persons were identified - 404 in South Africa (32% prevalence) and 232 (11% prevalence) in Uganda. Of the 636 HIV+ persons identified, 230 (36%) were newly-identified. The median CD4 count was high: 456 (IQR, 289-633). At baseline 254/636 (40%) of HIV+ persons were on ART, and 126/636 (20%) were not on ART but were ART eligible by national guidelines (CD4≤350 cells/μL). Mean viral load among all HIV+ persons who reported not being on ART at baseline was 3.86 log10 copies/mL.

By month 12, >97% of HIV+ persons visited an HIV clinic and 142 initiated ART, including 94/126 who were eligible for ART at baseline (CD4≥350 cells/μL). 570 (90%) of HIV+ persons had a month 12 viral load, including 114/126 (90%) of ART eligible participants at baseline. From baseline to month 12, mean HIV viral load decreased 0.55 log10 copies/mL (p<0.001) among all (N=570) HIV+ persons, 0.93 log10 copies/mL (p<0.001) among 331 HIV+ persons not on ART at baseline, and 1.96 log10 copies/mL (p<0.001) among 114 ART eligible persons who were not on ART at baseline. The proportion of HIV+ persons with a viral load of <1,000 increased from 50% to 65% (p<0.001). In multivariate analysis, higher baseline viral load was associated with increasing access to HIV care and prevention when combined with proactive linkage strategies. Community-based HIVST offers high potential to increase knowledge of HIV status, assisting with increasing access to HIV care and prevention when combined with proactive linkage strategies.

**Conclusions:** Uptake of HIVST, subsequent linkage into care, and accuracy were high with this strategy. Coercive testing and retesting on ART are concerning aspects of HIVST that need to be anticipated and discouraged. Community-based HIVST offers high potential to increase knowledge of HIV status, assisting with increasing access to HIV care and prevention when combined with proactive linkage strategies.

**149 Enhanced HIV Surveillance To Evaluate the National Response To HIV/AIDS in Kenya**

William Maina1, Davies Kinanga1, Ibrahim Mohammed1, Mamo Umuro1, Macdonald Obudho2, George Kichamu1, Patrick Mureithi2, Willis Akhwale1, Kevin M. De Cock1, Andrea A. Kim1

**Background:** Kenya has conducted two AIDS Indicator surveys (AIS) to monitor HIV prevalence and the impact of HIV care, treatment, and prevention services in the country. The first AIS was conducted in 2007 (KAIS 2007) and the second in 2012 (KAIS 2012).

**Methodology:** KAIS 2012 used a two-stage stratified cluster sampling design to achieve a nationally representative sample. Questionnaires were administered to persons aged 15-64 years, and blood was collected from persons aged 18 months-64 years for HIV, CD4, and viral load testing. All analyses were weighted to account for the sampling design and non-response. Estimates from KAIS 2012 were compared with estimates from KAIS 2007 to measure programmatic progress from 2007 to 2012. A z-test was used to test for differences in proportions between the two surveys.
**Results:** Overall, 16,383 persons aged 15-64 years and 6,302 children aged 18 months-14 years were eligible in KAIS 2012. HIV prevalence was 5.6% (95% confidence interval [CI] 4.9-6.3) among persons aged 15-64 years and 0.9% (CI 0.5-1.3) among children. In 2007, HIV prevalence was 7.2% (CI 6.6-7.9) among persons aged 15-64 years. In 2012, 72% had ever been tested for HIV compared to 34% in 2007 (p<0.001). Among HIV+ persons, 47% correctly reported their HIV+ status compared to 16% in 2007 (p<0.001). The percentage of circumcised men increased from 85% in 2007 to 91% in 2012 (p<0.001), with the largest increase observed in Nyanza, from 48% in 2007 to 66% in 2012 (p<0.001). Among women who gave birth in the past five years and were diagnosed with HIV during their last pregnancy, 90% received prevention of mother-to-child transmission interventions. Among HIV+ persons aware of their infection, 89% were taking cotrimoxazole compared to 76% in 2007 (p<0.001). Overall, 59% of HIV+ persons were eligible for antiretroviral therapy (ART) based on the national ART guidelines (CD4≤350 cells/μL, tuberculosis disease, or current ART use). Among those eligible, 61% were receiving treatment, and of those, 75% were virally suppressed. Based on the 2013 World Health Organization (WHO) treatment guidelines (CD4≤500 cells/μL, tuberculosis disease, pregnant or breastfeeding women, discordant couples, or current ART use), 77% were eligible for ART, and of those, 46% were receiving ART.

**Conclusions:** KAIS 2012 provides evidence that significant progress has been made in Kenya in the areas of HIV prevention, care, and treatment. Should Kenya adopt the new WHO treatment guidelines, need for ART increases by nineteen percentage points and coverage decreases by fifteen percentage points, representing an additional 214,000 persons who will need to be reached. These data will be instrumental to inform implementation of strategies and new national policies for HIV control in Kenya.

**Unequal Benefits From ART: A Growing Male Disadvantage in Life Expectancy in Rural South Africa**

Till Barnighausen1, 2, Abraham J. Herbst3, Frank Tanser2, Marie-Louise Newell1, 3, Jacob Bor4

1Global Health and Population, Harvard School of Public Health, Boston, MA, United States, 2Africa Centre for Health and Population Studies, Mtubatuba, South Africa, 3University of Southampton, Southampton, United Kingdom, 4Department of International Health, Boston University School of Public Health, Boston, MA, United States

**Background:** Women have suffered the disproportionate burden of HIV infection in South Africa. However, with the scale-up of antiretroviral therapy (ART), women have been found to perform better throughout the “cascade of care”, including: higher rates of HIV testing, earlier ART initiation, better adherence and retention, and better clinical prognosis. To date, no study has assessed the implication of ART scale-up on sex-disparities in all-cause and HIV-specific mortality at the population level.

**Methodology:** Demographic data on 54,477 women (6508 deaths from all causes and 3925 HIV-related deaths) and 46,809 men (6552 deaths from all causes and 3722 HIV-related deaths) were collected by health and demographic surveillance at the Africa Centre for Health and Population Studies for the period 2000-2011 for all members of all households in a 438 km² surveillance area in rural KwaZulu-Natal. Cause of death was ascertained by verbal autopsy. Data were linked at the individual level to clinical records from the public-sector HIV treatment and care program. Annual rates of HIV-related and all-cause adult mortality were assessed separately for men and women. Annual female-to-male rate ratios were estimated in Poisson regression, with detailed controls for age. Trends in adult life expectancy and HIV-cause-deleted adult life expectancy were calculated. Finally, to illuminate opportunities for intervention, we assessed the proportion of HIV deaths in 2011 that accrued to men and women who never sought care for HIV in the public sector.

**Results:** Following the beginning of ART scale-up in 2004, HIV mortality declined among both men and women. The female-to-male rate ratio for HIV mortality declined from 1.05 (95%CI 0.91-1.21) in 2004 to 0.75 (0.58-0.96) in 2011. Adult life expectancy improved for both men and women during the period of study (by 9.0 and 13.2 years respectively); however, the gap between female and male adult life expectancy nearly doubled (from about 4.5 years in 2004 to nearly 9 years in 2011). For men (women), 57% (41%) of HIV-related deaths occurred among persons who never sought care for HIV.

**Conclusions:** ART scale-up has led to a much larger reduction in HIV mortality among women than among men, at the population level. A critical source of this disparity is the high number of deaths occurring among men who never seek clinical care for HIV. Further efforts to recruit men into HIV care and treatment are needed.
A New Paradigm for Evaluating the HIV Care Cascade
Margaret L. McNairy, Matthew Lamb, Batya Elul, Elaine Abrams, Wafaa El-Sadr, The Identifying Optimal Models of HIV Care in Africa Study
ICAP Columbia University, New York, NY, United States

Background: The traditional HIV care cascade may underestimate program performance by focusing on ART retention as the primary outcome, with the exclusion of pre-ART outcomes and the timeliness of achievement of each step. We evaluated outcomes in 4 African countries using an alternate cascade that examines outcomes of all patients since enrollment in HIV care.

Methodology: Data from patients ≥15 years enrolled at clinics in Kenya, Mozambique, Rwanda and Tanzania from 1/2005-6/2011 were used. Retention was defined as percent known to be alive and attending clinic; lost to follow-up (LTF) as no clinic visit for >6 months (M) for ART and >12M for pre-ART patients. Cumulative incidence of retention 12M post ART start was done using Kaplan-Meier methods. Traditional cascade steps were: 1) assess for ART eligibility, 2) initiate ART for eligible patients, and 3) 12M retention post ART start. The alternate cascade reports the same steps at 3M and 12M post enrollment in care, including pre-ART outcomes.

Results: 390,603 patients completed ≥1 one follow-up visit at 217 ICAP-supported clinics. With the traditional cascade, 89% had ART eligibility assessed; of those, 48% were ART-eligible and 67% of eligible patients started ART. 91,211 (23% of all enrolled in care and 77% of all who initiated ART) were retained at 12M on ART. Using the alternate cascade, a similar percent had ART eligibility assessed within 3M and 12M of enrollment (87% vs 89%). For ART-eligible patients, 56% started ART within 3M with an additional 11% in 12M. 248,192 pre-ART patients had no outcomes reported as per the traditional cascade, but in the alternate cascade, pre-ART outcomes at 12M were 38.5% retained in care, 54% LTF, 2.9% dead, and 4.6% transferred. Among the pre-ART patients retained in care, 20% were ART-eligible but did not start ART. Compared to 23% retention 12M after ART start in the traditional cascade, the alternative cascade estimated that 56% of all patients enrolled in care were retained at 12M (fig 1).

Conclusions: The alternate cascade offers a more comprehensive assessment of program performance by including pre-ART patient outcomes and timeframes for each step. Use of both cascades provides complementary information to target interventions that enhance patient and program outcomes.

Figure 1: Alternate Cascade by months after enrollment into HIV care (N = 390,603)

Moderate HIV Incidence and High ART Coverage in Rural Kwazulu-Natal: First Population-Based Survey
Helena Huerga1, Médecins Sans Frontières, Adrian Puren2, Malika Bouhena1, Jihane Ben Farhat1, Alex Welte3, Lubbe Wiesner4, David Maman1, Jean-François Etard1, 5
1Epicentre, Paris, France, 2National Institute for Communicable Diseases of the NHLS, Johannesburg, South Africa, 3South African DST/NRF Centre of Excellence in Epidemiological Modelling and Analysis (SACEMA), Stellenbosch, South Africa, 4Division of Clinical Pharmacology, Cape Town, South Africa, 5Institut de Recherche pour le Développement, Montpellier, France

Background: Kwazulu-Natal has one of the highest HIV prevalence in the world. Accurate data on HIV prevalence, HIV incidence and antiretroviral therapy (ART) services coverage are essential to define appropriate strategies of intervention in population. We assessed HIV prevalence, HIV incidence and ART coverage in Mbonongwane and Eshowe in Kwazulu-Natal, South Africa. Other HIV care services indicators were also evaluated.
Methodology: Cross-sectional population-based survey. A cluster sampling and geospatial random selection was used to identify the households visited. Persons aged 15-59 years living in the area were eligible. Face-to-face interviews were carried out followed by rapid HIV testing on site and blood collection for CD4 count, ART levels and viral load in HIV positive cases. ART coverage was defined as the proportion of HIV positive on ART (detectable blood levels) among those eligible according to current National Guidelines. Incidence was estimated using HIV IgG avidity assay corrected by viral load and ART status.

Results: In total 2377 houses were visited, 6688 individuals were eligible and 5649 (84.5%) were included: 62.3% women and 37.7% men. Overall HIV prevalence was 25.2% (95%CI: 23.6-26.9). Prevalence in women was twice that of men: 30.9% (95%CI: 29.0-32.9) vs 15.9% (95%CI: 14.0-18.0). Prevalence reached 56.0% (95%CI: 51.7-60.3) in women aged 30-39 years. Overall HIV incidence was 1.2/100 person-years (PY) (95%CI: 0.2-2.1), 2.5 times higher in women than in men: 1.6/100 PY (95%CI: 0.2-0.9) vs 0.6/100 PY (95%CI: 0.0-1.5). Women aged 20-29 years had the highest incidence: 4.0/100 PY (95%CI: 1.1-6.9) vs 1.0/100 PY (95%CI: 0.0-2.5) in men. ART coverage was 75.0% (741 on ART/988 eligible) and was better for women than men: 78.5% vs 63.9% (p<0.001). Coverage increased with age: 60.5% in younger than 30 years vs 81.3% in older (p<0.001). Among all individuals, 81.4% declared to have had an HIV test previously (88.4% of women vs 69.8% of men, p<0.001). Of the HIV positive, 75.8% were aware of their status prior to the survey. Viral load suppression (<1000 copies/ml) was achieved in 89.6% of individuals on ART for more than 6 months. Among the others, resistance to ART was found in 58.1% (95%CI: 44.7-70.3). Conclusions: Overall HIV incidence was moderate in this high prevalence area. However, incidence was very high in young women, four times higher than in men. ART coverage and viral load suppression were relatively good and may be linked to incidence rates. HIV programs should maintain quality of care while carefully identifying HIV prevention and treatment strategies addressed to specific groups such young women for prevention and men for HIV testing and ART initiation. Surveys such as this are critical to evaluate ART programs and identify which groups to target.

Session S7 Symposium
4:00 PM – 6:00 PM  Room 304
Interferon: Whatever Turns You On

154 HIV-1 Evades Innate Immune Recognition Through Specific Co-Factor Recruitment
Greg J. Towers
University College London, London, United Kingdom

Background: HIV-1 is able to replicate in primary human macrophages without stimulating innate immune sensors despite reverse transcription of genomic RNA into double stranded DNA in the infected cell cytoplasm, an activity that might be expected to trigger innate pattern recognition receptors (PRRs). We hypothesized that if correctly orchestrated HIV-1 uncoating and nuclear entry is important for evasion of innate sensors, then manipulation of interactions with host factors that regulate these processes should trigger PRRs and stimulate type 1 interferon (IFN) secretion. For example, cofactors such as Cleavage and Polyadenylation Specificity Factor subunit 6 (CPSF6), Nup358, and Cyclophilin A have all been suggested to have a role in uncoating and/or nuclear entry. To test our hypothesis we used HIV-1 CA mutants N74D and P90A that are impaired in their interaction with CPSF6 or cyclophilins (Nup358 and CypA) respectively, leading to altered cofactor use at nuclear entry and retargeted integration preferences. To test the ability of these HIV-1 mutants to trigger innate sensors we infected human monocyte derived macrophages (MDM) with HIV-1 CA N74D or P90A and measured replication and production of soluble type-1 IFN. We found that HIV-1 encoding these CA mutations cannot replicate in MDM because it triggers cytoplasmic DNA sensors including cGAS, leading to nuclear translocation of NFκB and IRF3, the production of soluble type-1 IFN and induction of an antiviral state. Depletion of CPSF6 by shRNA expression in MDM allows wild type virus to trigger innate sensors and IFN production. In each case, suppressed replication is rescued by type 1 IFN-receptor (IFNAR2) blockade demonstrating a role for type 1 IFN in restriction. IFN production is dependent on viral reverse transcription consistent with viral DNA being the pathogen associated molecular pattern (PAMP). Finally, we show that we can pharmacologically induce wild type HIV-1 infection to stimulate IFN secretion and an antiviral state using a non-immunosuppressive cyclosporine analogue.

Conclusions: We conclude that HIV-1 has evolved to utilize CPSF6 and cyclophilins to cloak its replication allowing evasion of innate immune sensors and induction of a cell autonomous innate immune response in primary human macrophages. We hypothesise that successful infection of MDM depends on correctly orchestrated reverse transcription at the nuclear pore with a largely intact CA structure in complex with nuclear pore components including Nup358. We propose that uncoating HIV-1 with non-immunosuppressive cyclosporines will cause HIV-1 to trigger IFN production during transmission and act as a powerful prophylactic for HIV/AIDS and possibly an antiviral therapy.

155 Interferon Treatments for Chronic Hepatitis C
Markus H. Heim
University Hospital Basel, Basel, Switzerland

Background: Chronic hepatitis caused by infection with hepatitis C virus C (chronic hepatitis C (CHC)) is a leading cause of liver disease worldwide. For the past 25 years, recombinant interferon-α (IFNα) has been the main component of treatments for HCV infection. IFNα binds to its cognate cell surface receptor (IFNAR) and activates the Jak-STAT pathway, thereby regulating the expression of hundreds of genes. Collectively, IFNα induced effector proteins establish an antiviral state in the cell. IFNα signaling is regulated by inducible inhibitors of the Jak-STAT pathway such as SOCS1, SOCS3 and USP18. These negative regulators of IFNα signaling limit the therapeutic efficacy recombinant IFNα. Monotherapy with IFNα was the standard of care until 1998 and achieved a sustained virological response in 20-25% of patients. Treatment efficacy has shown a stepwise improvement following the pegylation of IFNα and its use in combination with other antiviral drugs, most notable ribavirin. However, viral escape mechanisms, refractory IFNα signalling in the liver and substantial drug toxicity still limit the efficacy of this treatment.
156 **Perturbing Interferon Signaling in SIV Infection**  
Daniel C. Douek  
*National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States*

**Background:** Two studies will be presented which describe the consequences of type I interferon receptor blockade and interferon alpha administration in rhesus macaques during SIV challenge and acute infection.

**Conclusions:** Emphasis will be on analysis of interferon stimulated gene expression, innate immunity, virus replication, CD4 T cell depletion and clinical outcome.

157 **Type 1 Interferon-Mediated Selective Pressure On HIV-1 Transmission**  
Persephone Borrow  
*University of Oxford, Oxford, United Kingdom*

**Background:** Understanding host mechanisms of immune control of HIV-1 replication during the earliest stages of infection prior to systemic virus dissemination constitutes a key first step in the rational development of novel strategies to limit virus transmission. Production of type 1 interferons (IFNs), pleiotropic innate cytokines that mediate direct antiviral activity and exert a multitude of immunoregulatory effects, is one of the earliest innate responses triggered during many virus infections. Although type 1 IFNs are known to be produced at initial sites of HIV-1 replication in the mucosa and draining lymph nodes, their role in restricting early HIV-1 replication and the mechanisms by which they mediate their antiviral activity are poorly understood. We recently demonstrated that transmitted-founder (TF) viruses are more resistant to control by IFN-alpha than viruses present in the same subjects during early chronic infection, when type 1 IFNs are produced at much lower levels. This suggests that type 1 IFNs exert selective pressure on HIV-1 replication at initial infection sites, resulting in establishment of systemic infection by relatively IFN-resistant viruses. Here, this hypothesis was explored further by studying the relative IFN resistance of viruses from a virologically-linked transmission pair. Matched pairs of TF and 6-month consensus infectious molecular clones were also used to explore the genetic basis of the IFN-alpha resistance of TF viruses and the interferon-stimulated genes (ISGs) exerting selective pressure on HIV-1 transmission.

**Conclusions:** Together, our results support an important role for type 1 IFN-mediated antiviral activity in restricting HIV-1 replication at initial infection sites, resulting in preferential establishment of systemic infection by relatively IFN-resistant viral variants. The IFN resistance of TF viruses typically declines within the first 6 months of infection. Viruses from different subjects lose resistance to different interferon-stimulated genes during early infection, suggesting that multiple antiviral ISGs contribute to restriction of HIV-1 transmission.

Session S8 Symposium  
4:00 PM – 6:00 PM  
**Room 311**  
**The Road To Elimination: Preventing and Treating HIV Infection in Infants**

158 **Treatment of Pregnant and Breast-Feeding Women: Evidence and Rationale for Option B+**  
Saeed Ahmed  
*Baylor College of Medicine, Lilongwe, Malawi*

**Background:** Option B+, initiation of lifelong antiretroviral therapy (ART) for all pregnant and breastfeeding women, has generated great excitement and conjecture that it is the most promising approach to achieving global Elimination of Mother-to-Child-Transmission. As of January 2014, at least 20 countries had endorsed B+ for their national PMTCT programs and were actively implementing or developing operational plans to switch over. What is the evidence for this rapidly developing consensus? This presentation will review the current evidence informing the proposed benefits and potential risks of the B+ approach, distinguishing individual health concerns for mother and child from program delivery and public health issues. Current experience from Malawi, that highlights both the potential and the challenges of this approach, will be discussed.

**Conclusions:** For mothers and infants, B+ may offer significant benefits for transmission prevention and maternal health. However, several studies raise concerns about the safety of ART exposure to fetuses and infants, resistance in exposed infants, as well as adherence to treatment of pregnant and breastfeeding mothers. For program delivery and public health, B+ simplifies the delivery of PMTCT services, and thereby presents distinct advantages in terms of improved feasibility, access, uptake, and potentially retention in care. Despite being more costly in the short-term, B+ will likely be cost-effective over time. Within Malawi, B+ implementation has resulted in a substantial improvement in access to PMTCT services, although challenges with uptake, retention, and delivery of early infant diagnosis services remain.

As national programs adopt this approach it will be critical to carefully assess both short and long-term maternal and infant outcomes.
159 Achievements and Challenges With Option B+ Implementation in the Field To Date
Edward Bitarakwate
Elizabeth Glaser Pediatric AIDS Foundation, Kampala, Uganda

Background: Following launch of the Global Plan towards the elimination of new HIV infections among children by 2015 and keeping their mothers alive in June 2011, and the April 2012 WHO programmatic update that offered Option B+ for PMTCT, several countries including Uganda adopted the provision of triple ARVs to HIV positive pregnant and lactating women for life regardless of CD4 count. Option B+ covers the estimated 40-60% of HIV positive pregnant women accessing PMTCT who need treatment for their own health and account for nearly 90% of all vertical HIV infections but also contribute to sexual transmission. However the adoption of option B+ requires changes in national policies and guidelines, more effective integration of ART into MNCH while at the same time eliminating critical losses along the PMTCT cascade in order to ensure universal coverage and retention of mother-baby pairs. While option B+ is likely to have more impact on elimination of HIV in the high HIV burden countries the implementation of this strategy also presents health system challenges. Continuous review of these large scale HIV test and treat interventions will provide valuable lessons to improve the effectiveness of Option B+ programs.

Conclusions: For optimal reduction of MTCT population coverage for maternal and infant ARV uptake needs to be improved. Monitoring tools need to be revised to ease completion and improve quality of data. Evaluation and adoption of service delivery models that foster optimal retention and adherence for mother-baby pairs initiating ART through PMTCT will maximize the impact of Option B+ towards EMTCT.

160 No Free Rides: Consequences of Fetal & Infant ARV Exposure Among Children Remaining HIV Uninfected
Kathleen M. Powis
Harvard Medical School, Boston, MA, United States

Background: Implementation of World Health Organization guidelines for prevention of mother-to-child HIV transmission (MTCT) will result in increased in utero and breastfeeding antiretroviral (ARV) exposure among HIV-exposed uninfected (HEU) infants. In some regions of Africa, more than 25% of all children will experience prolonged ARV exposure. Many studies have evaluated associations between in utero or direct infant exposure to ARVs and health outcomes, with conflicting findings. Most studies in this field have been observational, and multiple biases related to the complexities of defining ARV exposure groups, controlling for maternal HIV disease severity, and assessing infant outcomes contribute to limitations in interpreting reported results. Among the most consistently reported short-term concerns regarding ARV use in pregnancy, regardless of regimen, have been associations with infants born small-for-gestational-age, preterm deliveries (PTDs), and stillbirths; specific associations between use of protease inhibitor-based regimens and PTD have also been reported. Longer-term effects of in utero ARV exposures include lower weight-for-age and length-for-age (LAZ) z-scores among HEU children, and a potential association between tenofovir-containing regimens and lower mean LAZ in at least one recent study. Few studies have evaluated neurodevelopmental outcomes beyond early childhood, but limited data do not suggest adverse neurodevelopmental consequences from in utero ARV exposure. While nucleoside reverse transcriptase inhibitors have been implicated in mitochondrial toxicity, the long-term clinical significance of this finding for HEU children remains uncertain. Among children who have received direct prophylaxis with ARV agents in early infancy, zidovudine (ZDV) exposure has been associated with anemia and neutropenia up to 3 months following discontinuation, as has the combination of ZDV and nevirapine. Long-term follow-up data for HEU children with extended periods of direct ARV prophylactic exposures are lacking.

Conclusions: Available observational data raise concerns that in utero ARV exposure may lead to short- and long-term health consequences for some children, but little research has been performed to understand the biological pathways underlying these associations. Universal ARV treatment for HIV-infected women during pregnancy and breastfeeding, and direct infant ARV prophylaxis to prevent MTCT, are proven public health interventions capable of virtually eliminating MTCT if broadly applied. As MTCT prevention programs expand globally and universal ARV treatment is more widely adopted, optimizing the duration and type of ARVs used for MTCT programs will be of paramount importance for the health of HEU children.

161 Treatment of HIV-Infected Newborns: Why, When, and What To Start?
Ellen G. Chadwick
Northwestern University, Feinberg School of Medicine, Chicago, IL, United States

Background: Data have shown that early initiation of combination antiretroviral treatment (cART) in infants contributes to improved survival and neurodevelopmental, immunologic and growth outcomes. While cART cannot eradicate HIV infection in the majority of perinatally infected infants because of the long half-life of latently infected CD4 cells, time to achievement of viral suppression has been shown to correlate with the size of this resting CD4+ T cell reservoir in early-treated infants. The “Mississippi baby” has raised the possibility that neonatal cART may augment HIV-specific immune responses and block HIV persistence in acute infection, eventually leading to long-term control of HIV in the absence of therapy. This approach would require widespread availability of accurate neonatal diagnostic testing with rapid turnaround time and parental acceptance of aggressive antiretroviral therapy for high-risk infants. The choices for cART in the neonatal age group are limited by the lack of infant formulations and neonatal pharmacokinetic data for many antiretrovirals, as well as concerns about toxicity and efficacy.

Conclusions: The promise and challenges of early initiation of cART for high-risk infants will be discussed, but more data on pharmacokinetics, toxicity and efficacy of this approach are needed; if instituted, should be performed in a closely monitored setting, optimally within the context of a research study. At this time, empiric treatment interruption cannot be recommended until the durability of the approach in the Mississippi baby can be confirmed and the findings replicated in other children.
Intimate Infections: What’s Love Got To Do With It?

162 Oral Human Papillomavirus (HPV): Epidemiology and Role in Oropharyngeal Cancer
Gypsymber D’Souza
The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Background: Oral human papillomavirus (HPV) infection is now the major cause of oropharyngeal cancer and the incidence of this cancer is increasing in the U.S. People with HPV are at increased risk of HPV infection and HPV-related oropharyngeal cancer, due to increased sexual exposure to HPV and the effects of immunosuppression.

Conclusions: Oral HPV infection is more common in men than in women and is more common in people with HIV. Most people clear oral HPV infections within one year on their own but incidence and persistence are increased among immunosuppressed individuals. Common questions about oral HPV transmission, protection from the HPV vaccine, and risk among people with HIV will be discussed.

163 Bacterial Vaginosis
Landon Myer
University of Cape Town, Cape Town, South Africa

Background: This session focuses on current evidence for the role of bacterial vaginosis (BV) in HIV acquisition and transmission, and based on this, how future research on the vaginal microbiome may help to inform HIV prevention interventions. Our understanding of normal and abnormal vaginal flora, including BV, has undergone radical shifts during the past decade. While our thinking about BV continues to evolve, it is best understood as a polymicrobial condition in which the lactobacilli species which dominate vaginal flora under normal conditions are replaced by diverse populations of anaerobic and facultative anaerobic organisms. Evidence points to the role of predisposing host factors, including hormonal and immunological parameters, in facilitating BV occurrence and persistence. BV is consistently associated with high risk sexual behaviours such as multiple partners and lack of condom use. However a specific sexual aetiology of BV remains elusive. Several prospective studies have found that the presence of BV or abnormal vaginal flora in HIV-negative women appears associated with increased risk of HIV acquisition. This evidence is summarized in recent meta-analyses finding an increased risk of HIV infection in women with BV compared to women with normal vaginal flora, independent of measured sexual risk behaviours (hazard ratio, 1.69; 95% confidence intervals, 1.36-2.10). A range of mechanisms have been posited to explain this association. However the absence of a clear mechanistic model for vaginal HIV acquisition, coupled with well-documented challenges in adjustment for covariation in sexual risk behaviours, limit insights from existing epidemiological data. Also, BV occurs more commonly in women infected with HIV, and recently a groundbreaking study of serodiscordant partnerships demonstrated that BV was associated with increased risk of female-to-male HIV transmission; this finding is supported by studies showing increased shedding of HIV in the vagina under conditions of BV.

Conclusions: Given the available evidence, strategies to treat BV for HIV prevention are of clear interest. Yet the effective treatment of BV is notoriously challenging, with recurrence commonly observed following existing therapies in many women. Altogether it seems unlikely that additional epidemiologic studies investigating the association between BV and HIV acquisition, or intervention trials using existing treatment modalities, will yield significant new advances in HIV prevention. More productive new directions are likely to result from either more specific microbiologic definitions of BV that can be applied in studies of BV prevention, and/or more clearly defined mechanisms of female HIV acquisition that may be related to the vaginal microbiome.

164 Outbreak of Invasive Meningococcal Disease Among Men Who Have Sex With Men — New York City, 2010-2013
Alison D. Ridpath
New York City Department of Health and Mental Hygiene, New York, NY, United States

Background: During August 2010-February 2013, the New York City (NYC) Department of Health and Mental Hygiene (DOHMH) received 22 reports of serogroup C meningococcal (Neisseria meningitidis) disease (MenC) among men who have sex with men (MSM). Previous recognized outbreaks of MenC among MSM have occurred in Toronto in 2001 and Chicago in 2003. In the United States overall, MenC has a case-fatality rate of 15%. Cases in the NYC outbreak were identified through mandatory reporting by laboratories and health care providers; patients and providers were interviewed. DOHMH investigated to identify risk factors for infection, determine how the disease was spreading among this population, and implement control measures.

Conclusions: An outbreak of MenC occurred among NYC MSM with a case-fatality rate of 32%, twice the national rate. Common characteristics among cases included being HIV-infected (12 [55%]), black (11 [50%]), and a Brooklyn resident (10 [45%]). At least 5 (23%) patients met their sexual partners online during the month before illness. DOHMH responded to the outbreak by routine administration of antibiotic prophylaxis to close contacts of all patients and by developing targeted vaccine recommendations, initially for HIV-infected MSM residing anywhere in NYC, and ultimately expanding to MSM, regardless of HIV status, residing anywhere in NYC and who have close or intimate contact with men met online, with a digital application, or at a bar or party. DOHMH disseminated information about the outbreak and the need for vaccination to the MSM community, community-based organizations, and providers. Outreach included direct communication through conventional and social media, lectures, group meetings, and vaccination events at MSM-friendly bars, clubs, and Gay Pride events. Approximately 2,000 informational posters and 70,000 informational postcards were distributed. Social media dissemination included advertisements on sites where MSM meet sexual partners, Facebook messages, outreach to prominent bloggers, and e-mails to reach the population at risk. By December 1, 2013, ~23,448 doses of meningococcal vaccine had been administered by providers in NYC. The last
case of MenC in a NYC MSM was reported in February 2013. A multifaceted approach, involving prophylaxis of close contacts, DOHMH vaccination recommendations to targeted groups of MSM, and community outreach, appears to have been successful in decreasing transmission.

165 Lymphogranuloma venereum
David A. Lewis
National Institute for Communicable Diseases, Johannesburg, South Africa

**Background:** Lymphogranuloma venereum (LGV), caused by lymphotropic invasive strains of *Chlamydia trachomatis* (L1-L3 serovars), is a sexually transmitted infection characterised by severe inflammation, often with systemic symptoms. The clinical course of LGV can be divided into three stages. The primary stage, often unnoticed by the patient, consists of a small painless papule which may ulcerate. The secondary stage occurs a few weeks later and may manifest as either regional bubo formation or as the anorectal syndrome with haemorrhagic proctocolitis. The latter typically occurs in men-who-have-sex-with-men (MSM) or women practicing receptive anal intercourse. If left untreated, LGV may result in the tertiary stage characterized by extensive fibrosis of tissue, strictures and genital elephantiasis. LGV is endemic in parts of Africa, Asia, South America and the Caribbean. More recently, LGV has re-emerged among MSM in Europe and North America. Molecular typing has demonstrated that the majority of the European LGV-associated *C. trachomatis* strains are clonal (serovar L2b), whilst the North American strains are more diverse. Accordingly, it has been hypothesized that the L2b variant was recently imported into Europe from North America. Anorectal LGV in MSM has been strongly associated with HIV seropositivity. This observation may be explained by serosorting, increased biological susceptibility to LGV infection, epidemiological synergy with LGV leading to increased HIV acquisition and, possibly, the effects of the immune restoration inflammatory syndrome associated with the commencement of antiretroviral therapy. Diagnosis of LGV has traditionally relied upon serological techniques; these are only really useful for diagnosing LGV from the secondary stage onwards. Following the re-emergence of LGV in the northern hemisphere, a number of in-house nucleic acid amplification tests (NAATs) have been developed which can diagnose LGV infections from the primary stage onwards. In those situations where LGV-specific NAATs are unavailable, treatment for LGV is recommended in cases of proven anorectal chlamydial infection in MSM patients when proctitis is visualized by proctoscopy, white cells are detected at levels >10 cells per high power field in anorectal smears and when the patient is known to be HIV-infected. LGV is best treated with a 3-weeks’ course of doxycycline (100 mg 12-hourly) or, alternatively, with a 3-weeks’ course of erythromycin (500 mg 6-hourly).

**Conclusions:** LGV has re-emerged as an important STI among HIV-infected MSM. Clinicians should consider LGV as a differential diagnosis for proctocolitis and genital ulceration in this patient group. Where possible, LGV-specific NAATs should confirm a presumptive LGV diagnosis.
CDK2 But Not CDK1 Phosphorylates SAMHD1 in Primary Macrophages

Alba Ruiz1, Eduardo Paule1, Ester Ballana1, Albert Gubern1, Eliseo Martin-Arias2, Francesc Posas2, Bonaventura Clotet1, José A. Esté1

1 AIDS Research Institute - IrsiCaixa, Badalona, Spain, 2 Centro de Biología Molecular Severo Ochoa, Consejo Superior de Investigaciones Científicas, Universidad Autónoma de Madrid, Madrid, Spain

Background: SAMHD1 is an HIV-1 restriction factor present in lymphocytes and macrophages that is deactivated by phosphorylation. The mitotic cyclin-dependent kinase (CDK) 1 has been proposed as responsible for phosphorylation-dependent regulation of SAMHD1 activity in immortalized cells. We wanted to study whether other CDK, different from CDK1, may play a role in regulating SAMHD1 in primary monocyte-derived macrophages (MDM).

Methodology: CD14+ monocytes were isolated and transfected with small interfering RNA (siRNA) against different CDK. Transfected monocytes were differentiated in macrophages using M-CSF. RNA interference was assessed by quantitative PCR (qPCR) and western blot. MDM were infected with a VSV-pseudotyped NL4-3 GFP-expressing virus or full-replicative R5 strain BaL. Proviral DNA formation was quantified by qPCR and HIV replication measured by flow cytometry. SAMHD1 phosphorylation and CDK2 activation were analyzed by immunoblotting. Recombinant CDK1, CDK2 and CDK6 were used in an in vitro kinase assay using HA-purified SAMHD1 in the presence of radioactive ATP.

Results: We effectively downregulated (>80%) CDK1, CDK2, CDK4, CDK5 and CDK6 mRNA compared to mock-transfected cells or cells transfected with a non-targeting siRNA (siNT) in primary monocyte-derived macrophages (MDM). Protein downregulation of CDK1, CDK2 and CDK6 was further confirmed by western blot. siRNA-mediated knockdown of CDK1, CDK2 and CDK6 but not CDK4, CDK4 or CDK5 led to reduced SAMHD1 phosphorylation measured by western blot. Similarly, siRNA knockdown of CDK2 and CDK6 but not CDK1, CDK4 or CDK5 inhibited proviral DNA formation (~60% and ~80%, respectively) in macrophages infected with a VSV-pseudotyped NL4-3 GFP-expressing virus or the fully replicative R5-tropic strain BaL. Moreover, knockdown of CDK2 and CDK6 significantly reduced HIV-1 replication (p<0.001) quantified by flow cytometry. Confirmatory siRNA sequences targeting CDK2 and CDK6 showed similar effects on infection and proviral DNA formation after HIV-1 infection.

We also found that SAMHD1 is a substrate of CDK2 in vitro, being even more efficient than CDK1 in phosphorylating it. In contrast, we could not detect CDK6-mediated phosphorylation of SAMHD1. However, CDK6 siRNA-mediated downregulation led to reduced activation of CDK2, suggesting that CDK6 signals upstream CDK2.

Conclusions: Our results provide additional support to the role of CDK-dependent phosphorylation of SAMHD1 in mediating restriction of HIV-1, but argue against the in vivo relevance of CDK1 as the single kinase responsible for SAMHD1 phosphorylation. CDK2 but not CDK1 regulates SAMHD1 phosphorylation, leading to inhibited proviral DNA formation and reduced HIV-1 replication in primary human macrophages.

171LB p21 Regulates the HIV-1 Restriction Factor SAMHD1

Alba Ruiz1, Eduardo Paule1, Eva Riveira-Munoz1, Marc Permanyer1, Roger Badia1, Oliver T. Keppler2, Bonaventura Clotet1, Ester Ballana1, Jose Este1

1 AIDS Research Institute - IrsiCaixa, Badalona, Spain, 2 Institute for Medical Virology, Frankfurt, Germany

Background: CDK1A1 (p21) is a cyclin-dependent kinase (CDK) inhibitor controlling cell cycle progression through binding and activation of cyclin-CDK complexes. p21 expression has been shown to restrict HIV-1 replication in macrophages by controlling the expression of the RNR2 subunit of the ribonucleotide reductase that, in turn, controls the intracellular deoxynucleotide (dNTP) pool required for HIV-1 reverse transcription. dNTP levels are also tightly controlled by the dNTP triphosphohydrolase SAMHD1. We have evaluated the role of p21 in SAMHD1-mediated restriction of HIV infection.

Methodology: RNA interference was used to evaluate the role of p21, CDKs and SAMHD1 function in M-CSF monocyte derived macrophages (MDM). Protein expression was evaluated by mRNA qPCR or by Western blot of the corresponding factor. SAMHD1 phosphorylation at residue T592 was used as a marker of SAMHD1 inactivation. HIV-1 infection was monitored by total proviral DNA or GFP expression of a pseudovirus expressing the VSV envelope and the GFP gene in the presence or absence of the SIVmac Vpx. FACS measurement of Ki67+ cells was used as a marker of cell proliferation.

Results: Monocyte stimulation with M-CSF leads to differentiation into macrophages and cell proliferation. RNAi of p21 expression led to an increase in the number of Ki67+ cells. Susceptibility to HIV-1 replication correlated to the degree of SAMHD1 inactivation as measured by SAMHD1 phosphorylation at T592. Delivery of SIVmac Vpx induced SAMHD1 degradation and subsequently increased virus infection. Under these conditions, siRNA-induced downregulation of p21 strongly enhanced the phosphorylation and reduced HIV-1 replication, followed by an increase in HIV-1 proviral DNA formation and virus infection without affecting the overall SAMHD1 expression. The increased HIV-1 replication observed after SAMHD1 degradation was not affected or further enhanced by downregulation of p21, suggesting that the effect of p21 was indeed dependent on SAMHD1 expression.
SAMHD1 activity in primary cells (MDM and CD4+ T lymphocytes) was dependent on CDK2 as specific pharmacological inhibition or siRNA of CDK2 blocked SAMHD1 phosphorylation, proviral DNA formation and HIV-1 replication.

Conclusions: Our results strongly suggest that p21 positively correlates with the degree of SAMHD1 HIV-1 restriction. The restriction induced by p21 is dependent on CDK2 controlling SAMHD1 function. Cell cycle control must include a coordinated regulation of RNR2 and SAMHD1 as both tightly regulate dNTP availability. CDK2 activity may be the underlying mechanism explaining p21-mediated control of both RNR2 and SAMHD1 and their control of the dNTP pool required for cell proliferation and virus replication, opening new alternatives for the control of HIV-1 infection.

168 Inhibitors of CDK2 and CDK6 Block HIV-1 RT Through the Control of SAMHD1 Activity
Duo Li1, Erika Schlaepfer1, Caitlin Knowlton2, Baek Kim2, Annette Audigé1, Roberto Speck1
1Division of Infectious Diseases and Hospital Epidemiology, University Hospital of Zurich, Zurich, Switzerland, 2Center for Drug Discovery, Department of Pediatrics, Emory University, Atlanta, GA, United States

Background: SAMHD1 inhibits HIV-1 reverse transcription by decreasing the pool of intracellular deoxynucleotides in myeloid and lymphoid cells. The activity of the HIV-1 restriction factor SAMHD1 is controlled by cyclin-dependent kinase (CDK)-mediated phosphorylation. However, the exact mechanism of SAMHD1 regulation in primary cells is unclear.

Methodology: Human primary monocytes obtained from PBMC were differentiated into macrophages with M-CSF. CD4+ T lymphocytes were obtained from PBMC and stimulated with PHA/IL-2. Cells were pre-treated with CDK inhibitors and then infected with a GFP-expressing HIV-1 or R5-tropic virus BaL. Proviral DNA formation was measured by quantitative PCR and infection assessed by flow cytometry. SAMHD1 was degraded treating cells with viral-like particles carrying Vpx (VLP-Vpx).

Results: Pan CDK inhibitors roscovitine and purvalanol A showed in vitro activity against several CDK, including CDK2 and AT7519 is a preferential inhibitor of CDK2. These CDK inhibitors reduced SAMHD1 phosphorylation in macrophages and CD4+ T lymphocytes as measured by Western blot analysis. HIV-1 replication was blocked in primary macrophages by roscovitine (47.3%±3.9; n=4), purvalanol A (55.7%±15.7; n=4) and AT7519 (66.4%±3.8; n=4) at subtoxic concentrations as measured by the colorimetric MTT assay. CDK inhibitors blocked the formation of proviral DNA, indicating an effect on the reverse transcription step. Similar results were obtained in primary CD4+ T lymphocytes. In addition to these broad-spectrum CDK inhibitors, we tested the antiviral activity of palbociclib, a potent and selective CDK6 inhibitor. Palbociclib potently inhibited SAMHD1 phosphorylation, HIV-1 reverse transcription and HIV-1 replication (99.5%±0.2; n=4). Notably, treatment of macrophages with palbociclib led to reduced CDK2 activation, measured as the phosphorylation of the T-loop at the Thr160. The antiviral effect of all CDK inhibitors was lost when SAMHD1 was degraded using VLP-Vpx, providing further evidence for a role of SAMHD1 in mediating the antiretroviral effect.

Conclusions: Our results indicate that SAMHD1-mediated restriction of HIV-1 infection is controlled by CDK2 as previously suggested, but point to a preferential role for CDK2 and CDK6 as mediators of SAMHD1 activation. Our study provides a new signalling pathway susceptible for the development of new therapeutic approaches against HIV-1 infection.

169 Vpx Mediated Degradation of SAMHD1 Does Not Render HSCs More Permissive To Lentiviral Gene Transfer
Duo Li1, Erika Schlaepfer1, Caitlin Knowlton2, Baek Kim2, Annette Audigé1, Roberto Speck1
1Division of Infectious Diseases and Hospital Epidemiology, University Hospital of Zurich, Zurich, Switzerland, 2Center for Drug Discovery, Department of Pediatrics, Emory University, Atlanta, GA, United States

Background: Understanding how to achieve efficient transduction of hematopoietic stem cells (HSCs), while preserving their self-renewing capacity, is key for applying lentivirus-based gene engineering methods in Phase I/II clinical trials. The sterile alpha motif (SAM) domain and HD domain-containing protein 1 (SAMHD1) was recently identified as a HIV-1 restriction factor in myeloid and resting CD4+ T cells that interferes with reverse transcription by decreasing the nucleotide pools. HIV-2 and SIV have evolved to counteract the effects of SAMHD1 by their accessory protein Vpx, which targets SAMHD1 for proteasomal degradation. We hypothesized that SAMHD1 also interferes with HIV-1-vector-based HSCs transduction.

Methodology: We used Vpx-mediated degradation of SAMHD1, shRNA to SAMHD1, HIV-2- or SIV- based lentiviral vectors or provided an excess of deoxynucleoside triphosphates (dNTPs) or deoxynucleoside (dNs) to relieve a potential block of SAMHD1 in HSCs. In addition, Alu-PCR was used to identify and characterize the integrated provirus in HSCs and monocyte-derived macrophages (MDMs).

Results: Our results show that SAMHD1 is highly expressed in HSCs cultured in a medium enriched with cytokines conventionally used for transduction of HSCs. In contrast, uncultured HSCs have poor SAMHD1 expression. Expression levels of SAMHD1 in cultured HSCs are comparable to those found in myeloid cells, including monocytes and MDMs. However, Vpx+ VLPs, dNs or shRNA for silencing SAMHD1 and HIV-2- or SIV- based lentiviral vectors do not relieve a potential block in reverse transcription in HSCs that would result in a higher transduction rate. Notably, while Vpx+ VLPs resulted in a vigorous decrease of SAMHD1 in HSCs, the remaining SAMHD1 level is still remarkably high. Last but not least, Vpx+ VLPs lead to a striking increase of dNTPs in MDMs but not HSCs.

Conclusions: In summary, HSCs, unlike quiescent cells, express high levels of SAMHD1. However, the Vpx-mediated decrease of SAMHD1 levels was not associated with a higher lentiviral-based transduction rate. These data imply that other restriction factors might be operative in lentiviral transduction of HSCs.
Zinc–Finger Endonuclease Targeting LEDGF/p75 Inhibits HIV-1 Integration

Roger Badia, Ester Ballana, Bonaventura Clotet, José Esté
IrsiCaixa AIDS Research Institute, Badalona, Spain

**Background:** Human immunodeficiency virus (HIV) requires several host factors to complete viral replication cycle. Genome editing using zinc-finger nucleases (ZFN) has been successfully applied to disrupt CCR5 or CXCR4 host factors, inhibiting viral entry and infection. Lens epithelium-derived growth factor (LEDGF/p75) is a lentivirus-specific cellular cofactor which directly interacts with viral integrase, tethering viral preintegration complex to the chromatin resulting in a integration site preference. The consequences of the integration site preference for latency and oncogenicity are still unclear.

**Methodology:** By co-immunoprecipitation combined with mass spectrometry we identified cellular proteins differentially interacting with HIV-1 and MLV. BET proteins specifically bind to the chromatin resulting in a integration site preference. BET proteins interact with MLV IN and direct integration towards transcription start regions. BET proteins specifically bind and co-localize with the MLV IN in the nucleus of the cell. The interaction is gammaretroviral-specific and mediated by the C-terminal domain of integrase and the extraterminal (ET) domain of BET. Interfering with chromatin interaction of BET proteins via the specific bromodomain inhibitors JQ1 and I-BET decreased MLV replication and MLV vector transduction 5-10-fold, without affecting HIV vector transduction. Quantitative PCR analysis revealed a block at the integration step. In addition, bromodomain inhibitors did not affect the late steps of viral replication. MLV integration site distribution strongly correlated with the BET protein chromatin binding profile. Finally, expression of an artificial fusion protein that merges the BET integrase binding domain with the extraterminal (ET) domain of BET Proteins Mediate Integration Site Selection of MLV Much Alike LEDGF/p75 in HIV Integration

Jan De Rijck, Christine de Kogel, Jonas Demeulemeester, Sofie Vets, Nirav Malani, Frederic Bushman, Frauke Christ, Rik Gijsbers, Zeger Debyser

**Background:** A hallmark of retroviral replication is stable integration of the viral genome in the host cell DNA. However, retroviruses do not integrate at random. Mediated by LEDGF/p75, lentiviruses preferentially integrate in the body of active transcription units. Gammaretroviruses, including Moloney Murine Leukemia Virus (MLV), favour transcription start sites and CpG islands. It is generally believed that cellular proteins target viral integration complexes to the chromatin resulting in a integration site preference. The consequences of the integration site preference for latency and oncogenicity are still unclear.

**Methodology:** Knockout ZFNs targeting the LEDGF gene (ZFN-LEDGF) were designed to specifically target the sequence nearby the integration binding domain (IDB) of LEDGF/p75 protein. TZM-bl cells were transfected with ZFN-LEDGF expressing plasmids carrying a ZsGreen reporter gene. Moreover, LEDGF/p75 knock-out cells were infected with HIV-1 R5 tropic BaL and the X4 tropic NL4-3 strains and infection was monitored by proviral and integrated viral DNA at 24h post infection and β–galactosidase assay 3 days after infection. AZT, AMD3100 and raltegravir were used as controls.

**Results:** A total of 15% of TZM-bl ZFN-LEDGF positive cells were obtained after transfection and cell sorting of GFP expressing cells. Assessment of ZFN-LEDGF efficiency in the deletion of the gene by heteroduplex formation and DNA sequence analysis, revealed two homozygotic cell clones with deletions ranging from 17 to 41 bp surrounding the target sequence of ZFN-LEDGF. We confirmed that ZFN-LEDGF successfully recognized the target region of the LEDGF gene, induced a frame shift of the coding region and resulted in the abolishment of LEDGF expression at mRNA and protein level. Functional assays revealed that infection with R5 BaL or X4 NL43 viral strains was impaired in LEDGF knock-out cells regardless of entry tropism (up to 85% inhibition, p<0.05). Disruption of LEDGF gene restricted HIV-1 provirus integration into host genome. However, residual infection was detected in LEDGF knock-out cells. Indeed, LEDGF knock-out restriction was overcome at high virus multiplicity of infection, suggesting alternative mechanisms for HIV-1 genome integration rather than LEDGF/p75. Observed residual integration was, however, sensitive to the integrase inhibitor raltegravir.

**Conclusions:** Genome editing is an incoming issue for HIV-1 research and treatment. Here, we describe a novel ZFN that effectively targets LEDGF gene which is involved at late steps of viral replication cycle. LEDGF knock-out cells represent potent tools to elucidate the role of HIV integration cofactors in virus replication. The ZFN-LEDGF becomes a potential antiviral agent to restrict HIV-1 integration.
172 Small-Molecule Inhibits HIV-1 Replication by Interacting With HIV Capsid

Atsuko Hachiya1, 2, 4, Anna Gros2, Karen A. Kirby2, Michaelidis Eleftherios2, Masami Maejima3, Wataru Sugiuira3, Kyeongeon Lee3, Vineet KewalRamani3, Kamlendra Singh2, Stefan G. Sarafianos2, 4
1Clinical Research Center, Laboratory of Infectious Diseases, National Hospital Organization, Nagoya Medical Center, Nagoya, Japan, 2C. S. Bond Life Sciences Center & Department of Molecular Microbiology and Immunology, University of Missouri School of Medicine, Columbia, MO, United States, 3HIV Drug Resistance Program, National Cancer Institute, Frederick, MD, United States, 4Department of Biochemistry, University of Missouri, Columbia, MO, United States

Background: HIV-1 capsid (CA) is a viral protein essential for early and late events of the replication cycle and so far CA has been an untapped target, thus providing excellent opportunities for the discovery of new antiretrovirals that act by novel mechanisms of action.

Methodology: We screened a library that interferes with multimerization of HIV-1 CA and identified a small molecule, 18E8, with antiretroviral activity of 18E8 in single- and multiple-round infection assays. To identify the antiviral target of 18E8 we selected resistance viral variants in in vitro serial passage experiments. To determine whether 18E8 affects the late step of the viral replication cycle, we conducted virus production assays, western blot analysis of viral supernatants and electron microscopy. To further gain insight into the mode of action of 18E8 and to determine the affected early step of the viral replication cycle, we performed synchronized time-of-drug-addition experiments that determine how long the addition of 18E8 could be postponed before losing its antiviral activity. To evaluate the effect of 18E8 on levels of different DNA forms, we used qPCR to detect late reverse transcriptase (RT) products, 2-LTR circles and integrated viral DNA.

Results: 18E8 showed broad antiretroviral activity against drug resistant and non-clade B viruses, but not against an HIV-1 core pseudotyped with VSV-G envelop. Experiments for the selection of drug resistance revealed that an A105T CA mutation confers resistance to 18E8, suggesting that it exerts its antiretroviral activity by binding to HIV-1 CA. 18E8 did not affect proper assembly of fully processed CA in nascent viral particle. By comparing its relative position in the time scale to that of drugs that target RT and integrase steps we demonstrated that 18E8 targets an early step in the HIV replication cycle, after reverse transcription. Consistent with these results, cell-cell fusion and primer extension by RT assays showed that 18E8 did not affect the viral entry or RT steps. Surprisingly, although 18E8 targeted CA, it decreased the amount of integrated viral DNA. 18E8-resistant virus carrying A105T in CA restored integration efficiency. It has been reported that antiviral host factor CPSF6 interacts with CA and restricts HIV-1 infection by preventing nuclear entry and integration of the viral dsDNA. HIV-1ΔCPSF6, which is unable to bind CPSF6, maintains 50% infectivity in TNPO3-deficient cells, and this infectivity is hypersusceptible to 18E8. Docking simulation suggests that 18E8 binds at the CPSF6 binding site and may affect interactions between the N-terminal domains of two CA monomers.

Conclusions: Our data suggest that 18E8 acts during nuclear import and affects integration by interacting with CA.

173 Resistance To HIV-1 Infection in PBLs From LGMD1F Patients Carrying a Genetic Defect in TNPO3

Mercedes Bermejo1, Mayte Coiras1, Sara Rodríguez-Mora1, Elena Mateos1, Ramón Martí1, Juan Vilchez1, Antonio Andreu2, Jose Alcamí1
1AIDS Immunopathology Unit, Instituto de Salud Carlos III, El Centro Nacional de Microbiología, Majadahonda, Madrid, Spain, 2Research Group on Neuromuscular and Mitochondrial Disorders, Vall d’Hebron Institut de Recerca, VHIR and CIBERER, Barcelona, Spain, 3Hospital Universitari i Politècnic La Fe, Department of Neurology, Universitat de València, and CIBERNED, Department of Medicine, Valencia, Spain

Background: Recently, a heterozygous single nucleotide deletion in transportin 3 (TNPO3) gene has been characterized as the elusive genetic defect leading to an autosomal dominant form of limb-girdle muscular dystrophy 1F (LGMD1F). TNPO3 is an essential factor in the HIV-1 viral cycle but its precise role in viral replication is a matter of controversy. We evaluated the susceptibility to HIV-1 infection of PBLs isolated from patients with LGMD1F disease and characterized the mechanism of restriction in the viral cycle.

Methodology: Monocyte-depleted PBLs isolated from four patients with LGMD1F and two healthy relative controls were activated with PHA/IL2 for 48h and then infected with NL4-3_renilla, VSV-αEnv-NL4-3_LUC, or R5 and R5X4 isolates from HIV-infected patients for 18h or 6 days. Viral retrotranscription, proviral integration, and episomic forms (2LTRs circles) were analyzed by TaqMan qPCR. Rate of TNPO3 wild-type (wt) and mutated forms was analyzed by allelic discrimination using TaqMan probes.

Results: PBLs from LGMD1F patients were fully functional. No defect in CD4,CCR5, CXCR4 or activation markers was found and T-cell proliferation remained in normal levels. TNPO3wt and mutated forms were expressed at similar levels. A strong reduction (90%) in HIV-1 replication was observed in 3 out of 4 patients as compared to controls. DNA proviral integration was reduced more than 90% in 3 out of 4 patients and 2LTRs circles were barely detected. The defect on TNPO3 showed lower effect on viral retrotranscription.

Conclusions: In vitro HIV-1 infection was sharply decreased in PBLs from patients carrying a single nucleotide deletion in one allele of TNPO3. Low detection of 2LTRs circles and strong decrease in proviral integration demonstrates that TNPO3 participates in a step previous to the nuclear import of the pre-integration complex. Surprisingly, despite the co-expression of similar levels of normal and mutated mRNA coding for TNPO3, HIV-infection was more than 50% inhibited, thereby suggesting an interaction between the wt and mutated forms of the protein.

174 HIV IntegraseR263A/K264A Is Defective for TRN-SR2/IN Interaction and Nuclear Import of the PIC

Stephanie Dehouwer, Jonas Demeulemeester, Wannes Thys, Zeger Debyser, Frauke Christ
Department of Pharmaceutical and Pharmacological Sciences, KU Leuven, Leuven, Belgium

Background: Transportin-SR2 (TRN-SR2/TNPO3) is a human karyopherin encoded by the TNPO3 gene. We identified TRN-SR2 as a binding partner of HIV-1 integrase (IN) and validated TRN-SR2 as an important cellular cofactor for the nuclear import of HIV-1. However, the question still remained whether the direct interaction between TRN-SR2 and IN mediates the nuclear import of HIV.
**Methodology:** By peptide screening we analyzed the interaction between TRN-SR2 and IN in molecular detail. Protein-protein interactions were verified by co-IP and AlphaScreen. We engineered site specific mutants in the C-terminal domain of HIV-1 IN that display reduced interaction with TRN-SR2 and studied their role in HIV replication using Q-PCR and fluorescence microscopy.

**Results:** Using the AlphaScreen protein-protein interaction assay we have been able to pinpoint the interacting hot spots in IN to R262/R263/K264 and K266/R269 in the IN C-terminal domain. We also identified a secondary interaction surface involving residues F185/K186/R187 and K188 in the catalytic core domain. Next, we introduced mutations at these positions in the C-terminal domain in the virus to corroborate the biological relevance of the interaction. Several mutations in the C-terminal domain of HIV IN inhibited the IN/IN-SR2 interaction and rendered the virus replication-deficient. Some mutants affected reverse transcription (RT) compromising analysis of HIV nuclear import. All mutants also affected integrase activity. Still, one mutant, INR263A/K264A, retained full RT activity but displayed a specific block at the level of nuclear import as measured by Q-PCR and fluorescence microscopy. Although this mutant was defective for integration, no increase in 2-LTR circles was detected. Moreover, HIV encoding INR263A/K264A showed reduced nuclear import when assayed with an eGFP-IN labeled HIV.

**Conclusions:** The INR263A/K264A mutation in the C-terminal domain of HIV-1 integrase reduces the interaction with TRN-SR2 and specifically blocks HIV replication at the stage of nuclear import, corroborating the importance of this direct protein-protein interaction in HIV nuclear import.

175 SHAPE-Directed Discovery of a Novel Structure in the HIV-1 RNA Polyadenylation Signal

Nathan A. Siegfried1, Steven Busan1, Gregory M. Rice1, Christine E. Hajdin1, Julie A. E. Nelson2, Kevin M. Weeks1

1Chemistry, Univ of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 2UNC Center for AIDS Research and Microbiology & Immunology, Univ of North Carolina at Chapel Hill, Chapel Hill, NC, United States

**Background:** Although polyadenylation at the 3’ end of HIV-1 RNA has been shown to be regulated by sequence elements in U3 and in R, its molecular mechanism remains incompletely understood and has not been studied in the context of the full-length genomic RNA. Selective 2’-Hydroxyl Acetylation analyzed by Primer Extension (SHAPE) technology produces RNA structural information at single nucleotide resolution. SHAPE data have previously been used to constrain RNA folding algorithms and model structures with high accuracy. Pseudoknots are RNA structures that occur when nucleotides in a loop region base pair with nucleotides outside of the parent helix. While rare, pseudoknots are often important for biological function in riboswitches, catalytic RNAs, and viral regulatory elements.

**Methodology:** SHAPE experiments were used to develop structural models for an entire NL4-3 HIV-1 RNA genome. A pseudoknot was predicted to form between sequences in U3 and R adjacent to the polyadenylation signal and was chosen for additional study. Site-directed mutagenesis of the NL4-3 sequence was used to disrupt 3 of the 7 base pairs in the predicted pseudoknot. The mutant and native sequence NL4-3 plasmids were transfected into 293T cells to produce virus that was titered on TZM-bl cells. Equal amounts of infectious virions were used to infect H9 and Jurkat T cells; p24 was measured in culture medium 4-6 days post-infection.

**Results:** There was little difference in virus production between the U3 mutant and native sequence NL4-3 after 293T transfection and infection of TZM cells. However, after infection of Jurkat and H9 cells with equal amounts of infectious virus, the mutant showed no spread in Jurkat and a slight decline in spread in H9 cells compared to the native sequence. Growth of the mutant virus in H9 cells over 3 weeks led to reversion of the mutations in one-half of the culture. SHAPE analysis of the mixture of mutant and revertant RNA indicated disruption of the putative pseudoknot in the mutant RNA.

**Conclusions:** SHAPE data can be used to identify biologically functional structures in HIV-1 RNA, including pseudoknots. Mutation of three bases on the U3 side of a putative U3-R pseudoknot led to reduced spread and fitness of the mutant virus, as evidenced by the rapid reversion of the mutations. These data support our model of a pseudoknot around the 3’ polyadenylation site of HIV-1 genomic RNA that is important to the replication cycle of HIV-1, likely in the regulation of polyadenylation.

176 HIV-1 Assembly On Intracellular Plasma Membrane-Connected Compartments of Human Macrophages

David O. Nkwe, Annegret Pelchen-Matthews, Mark Marsh

Laboratory for Molecular Cell Biology, University College London, London, United Kingdom

**Background:** In differentiated human monocyte-derived macrophages (MDM), HIV-1 assembles primarily on intracellular plasma membrane (PM) connected compartments (IPMC). It is unclear how the IPMC differs from the cell surface PM, or whether the IPMC is indeed the only site for virus assembly in MDM. As the endosomal sorting complex required for transport (ESCRT) machinery is required for the final scission events that release assembled virus from the PM, we inhibited ESCRT-mediated scission of HIV-1 in macrophages to generate stable budding intermediates in order to identify the main site(s) where virus is assembled in MDM.

**Methodology:** We used siRNA to deplete expression of the ESCRT pathway proteins Tsg101 and ALIX, or we generated HIV-1 mutants defective in ESCRT recruitment. Cells were either infected with virus or nucleofected with provirus. Virus release was characterised by western blotting, and the distribution of virus was analysed by immunofluorescence (IF). Electron microscopy (EM) was used to identify HIV-1 budding sites.
**LEDGIN (ALLINI) Disruption of HIV-1 Assembly Does Not Involve LEDGF/p75**

Hind J. Fadel1, James Morrison1, Dyana Saenz1, Stephen C. Ecker1, James R. Fuchs1, Mamuka Kvaratskhelia1, Eric M. Poeschl1

1Division of Infectious Diseases & Department of Molecular Medicine, Mayo Clinic, Rochester, MN, United States, 2Department of Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, United States, 3Ohio State University Center for Retrovirus Research, Columbus, OH, United States

**Background:** LEDGF/p75, the product of the PSIP1 gene, is an HIV-1 integration cofactor that tethers the viral pre-integration complex to the site of its subsequent integration. Allosteric integrase inhibitors or ALLINIs (also known as LEDGINs) disrupt the interaction of LEDGF/p75 with the HIV-1 IN dimer and impair integration. However, a considerably more potent (and apparently main) mechanism of ALLINI action was recently identified: disrupting proper particle assembly. It is not clear whether this antiviral effect involves LEDGF/p75. Some studies suggest that it is LEDGF/p75-independent but others suggest LEDGF/p75-dependence and, consistent with this, that LEDGF/p75 incorporation into HIV-1 particles occurs and is necessary for normal HIV-1 infectivity. RNAi-depleted cells still contain some LEDGF/p75 protein, and a fractionally minute LEDGF/p75 residuum can maintain integration cofactor function. Mouse PSIP1 gene knockout cell lines exist but cannot be used for HIV assembly studies. Here we definitively answer two questions: does LEDGF/p75 play a role in HIV-1 assembly and does the ALLINI antiviral mechanism involve LEDGF/p75? To do so, we used TAL effector nucleases (TALENs) to delete the PSIP1 gene from informative human cell lines.

**Methodology:** We designed and constructed multiple TALEN pairs that site-specifically target PSIP1. We used them to generate clonal Jurkat and 293T cell lines that are -/- for the entire 42 kb gene, and separately, -/- for the only the exons that encode the LEDGF/p75 integrase binding domain (IBD). Correct deletion of all PSIP1 alleles was verified at the DNA and protein levels, precise chromosomal deletion junctions were determined, and comprehensive viral life cycle analyses were conducted in the presence and absence of drug.

**Results:** HIV-1 integration is impaired, and spreading viral replication is blocked, but HIV-1 production and infectious particle assembly are normal in PSIP1 -/- cells. This is the case whether the entire gene is deleted or only the IBDencoding gene segment is deleted. We further determined that ALLINI potency for blocking HIV-1 infectious particle formation is unaffected by total removal of LEDGF/p75-encoding capacity from the cell. TALEN gene KO was efficient. For example, a third of single cell clones generated from a single transfection were found to contain bi-allelic gene disruptions due to NHEJ-generated indels at the specific target site, suggesting efficacy for gene targeting cure strategies aimed at this and other HIV dependency factor genes such as CCR5.

**Conclusions:** The main ALLINI mechanism is independent of LEDGF/p75. This protein also does not play a detectable role in particle assembly. The LEDGF/p75 cofactor role is confined to the integration step of the viral life cycle.

**Characterization of the Interaction Between Staufen-1 With HIV-1 Rev and HERV-K(HML-2) Rec**

Katharina Fiddeke, Alexander Rohde, Kirsten Hanke, Jula Wamara, Oliver Hohn, Norbert Bannert

HIV and Other Retroviruses, Robert Koch Institute, Berlin, Germany

**Background:** The Rev protein of HIV-1 is an RNA transport factor that enhances nuclear export of intron-containing retroviral transcripts and appears to be critical for various aspects of subsequent RNA utilization pathways. The cellular protein Staufen-1 is in several ways functionally related to retroviral RNA transport proteins. It shuttles RNA out of the nucleus and has previously been shown to become incorporated into HIV-1 particles by direct binding to the genomic RNA and to interact with the Gag protein of HIV-1, promoting Gag oligomerization and RNA encapsidation. Moreover, we have recently demonstrated that it interacts with Rev of HIV-1 and the Rec and Gag proteins of HERV-K(HML-2).

**Results:** In siRNA experiments, good knockdown efficiencies were achieved for ALIX and Tsg101, but effects on virus release were only modest, perhaps because many of the infected cells had escaped the knockdown. To address these complications, we mutated motifs in Gag p6 required for recruitment of Tsg101 (PTAP−) and ALIX (YP−), or deleted the entire p6 (Δp6). In MDM, the release of PTAP− and Δp6 viruses was inhibited more efficiently and to the same extent for both mutants, compared to the YP− mutant (63% vs. 29%). This showed that, as in other cells, Tsg101 is more important than ALIX for virus release in MDM. To analyse the global distribution of virus in the cells, we used IF. In a significant number of cells, both the WT and the PTAP− mutant viruses were found to assemble only at the IPMC (Fig 1). To verify these findings, we performed EM on MDM infected with PTAP− mutant viruses. Consistent with the IF data, we observed immature HIV-1 budding profiles mainly associated with the IPMC.

**Conclusions:** Our study is the first to provide conclusive evidence that the IPMC is the preferred assembly site for HIV-1 in MDM. Because macrophages are long-lived compared to T-cells, this “archiving” of HIV in the IPMC may conceal it from immune surveillance, which may have implications for HIV therapy and disease progression.

---

**LEDGIN (ALLINI) Disruption of HIV-1 Assembly Does Not Involve LEDGF/p75**

1Division of Infectious Diseases & Department of Molecular Medicine, Mayo Clinic, Rochester, MN, United States, 2Department of Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, United States, 3Ohio State University Center for Retrovirus Research, Columbus, OH, United States

**Background:** LEDGF/p75, the product of the PSIP1 gene, is an HIV-1 integration cofactor that tethers the viral pre-integration complex to the site of its subsequent integration. Allosteric integrase inhibitors or ALLINIs (also known as LEDGINs) disrupt the interaction of LEDGF/p75 with the HIV-1 IN dimer and impair integration. However, a considerably more potent (and apparently main) mechanism of ALLINI action was recently identified: disrupting proper particle assembly. It is not clear whether this antiviral effect involves LEDGF/p75. Some studies suggest that it is LEDGF/p75-independent but others suggest LEDGF/p75-dependence and, consistent with this, that LEDGF/p75 incorporation into HIV-1 particles occurs and is necessary for normal HIV-1 infectivity. RNAi-depleted cells still contain some LEDGF/p75 protein, and a fractionally minute LEDGF/p75 residuum can maintain integration cofactor function. Mouse PSIP1 gene knockout cell lines exist but cannot be used for HIV assembly studies. Here we definitively answer two questions: does LEDGF/p75 play a role in HIV-1 assembly and does the ALLINI antiviral mechanism involve LEDGF/p75? To do so, we used TAL effector nucleases (TALENs) to delete the PSIP1 gene from informative human cell lines.

**Methodology:** We designed and constructed multiple TALEN pairs that site-specifically target PSIP1. **Conclusions:** The main ALLINI mechanism is independent of LEDGF/p75. This protein also does not play a detectable role in particle assembly. The LEDGF/p75 cofactor role is confined to the integration step of the viral life cycle.
Methodology: Using pull-down and coimmunoprecipitation experiments along with deletion mutants we have mapped the interaction sites of Staufen-1 with Rev and Rec. The effect of Staufen-1 on nucleo-cytoplasmic export and translation was determined with reporter constructs in HEK 293T cells. Stress granules were induced with arsenite and the localization of the proteins in granules was investigated by immunofluorescence.

Results: Having demonstrated a direct interaction between Staufen-1 and HIV-1 Rev we found that the NLS of Rev is the region required for binding. In the Staufen-1 protein, the RBD3 domain is the main mediator of the interaction with Rev. This is in contrast to the situation with Rec, where binding is mediated primarily through the RBD4 domain. While Staufen-1 strongly enhances nucleocytoplasmic export and/or translation of unspliced HERV-K(HML-2) transcripts in the presence of Rec, this seems not to be the case for unspliced HIV-1 transcripts in the presence of Rev. Moreover, we demonstrate that under cellular stress conditions Rec and Rev associate in Staufen-1-positive stress granules. However, Staufen-1 appears to attract only Rec, but not Rev, into stress granules.

Conclusions: Although Staufen-1 interacts with both HIV-Rev and HERV-K(HML-2) Rec, only the nucleocytoplasmic transport and translation of HERV-K(HML-2) is significantly upregulated by Staufen-1. Our data also indicate that Rev and Rec are recruited into stress granules by different mechanisms.

The Role of RNA Interference in HIV-1-Infected Primary Human Monocyte-Derived Macrophages

Valentina Vongrado, Jochen Iming, Pejman Mohammadi, Shivendra Kishore, Lukasz Jaskiewicz, Michela Zavolan, Jonathan Hall, Niko Beerwinkel, Huldrych F Günthardt, Karin J Metzner

1Division of Infectious Diseases and Hospital Epidemiology, University Hospital Zurich, Zurich, Switzerland, 2Institute of Pharmaceutical Sciences, ETH Zurich, Zurich, Switzerland, 3ETH Zurich, D-BSSE, Basel, Switzerland, 4Computational and Systems Biology, University of Basel, Basel, Switzerland

Background: Micro RNAs (miRNAs) and other small noncoding RNAs (sncRNAs) are key players in post-transcriptional gene regulation. We and other groups have described the presence of HIV-1 derived sncRNAs in different experimental setups; however, so far their biological function remained to a large extent unknown. Here we used a global, comprehensive approach to investigate whether viral small RNAs may play a role in the RNA interference (RNAi) pathway in primary human monocyte-derived macrophages (MDMs). Specifically, we aimed to characterize the profiles of host and HIV-1 derived small RNAs and the possible impact of these RNAs on the viral life cycle.

Methodology: We applied Argonaute 2 (Ago2) photoactivatable ribonucleoside-enhanced crosslinking and immunoprecipitation (PAR-CLIP) to MDMs infected with HIV-1JRFL for 14 days from two different donors. It has been previously demonstrated that this approach enables identification of Ago2-bound miRNAs as well as of the miRNA-targeted mRNAs. Illumina sequencing was performed on PAR-CLIP and small RNA (18 to 30 nt) samples from the same donors, and small RNA sequencing was performed on HIV-1 infected MDMs from two additional donors.

Results: The analysis of PAR-CLIP data demonstrated the absence of viral RNAs in Ago2-RISC, suggesting that viral sncRNAs do not enter the canonical RNAi pathway in MDMs. However, small RNA sequencing on samples from the same MDM cultures confirmed the presence of HIV-1 sncRNAs, although expressed at low levels (< 0.5 % of total small RNA fraction). Most host miRNAs revealed no significant change in expression levels between infected and non-infected MDMs.

Conclusions: Our data indicate that it is unlikely that viral sncRNAs are incorporated as functional miRNAs or resemble targets for host miRNAs in Ago2-RISC. The presence of HIV-1 sncRNA as detected by small RNA sequencing implies alternative functional roles or biogenesis pathways. Future efforts are needed to uncover potential functions of HIV-1 derived sncRNAs in MDMs or other HIV-1 host cell types.

Induced Maturation of HIV-1 Virions

Barbara Mueller, Simone Mattei, Maria Anders, John A. G. Briggs, Hans-Georg Krausslich

1Infectious Diseases, Virology, University of Heidelberg, Heidelberg, Germany, 2EMBL, Heidelberg, Germany

Background: HIV-1 assembles at the plasma membrane of host cells as immature, non-infectious particles. Processing of Gag and Gag-Pol polyproteins catalyzed by the viral protease (PR) activates the viral enzymes and results in dramatic structural rearrangements within the particle. Formation of the mature HIV-1 core is a prerequisite for infectivity; processing and morphological maturation thus represent important targets for antiretroviral therapy. When and how fast the maturation event occurs are two basic questions that surprisingly still remain unanswered. Whereas the architecture of start and end point - the immature and mature virion - is well characterized, structural intermediates delineating the pathway of morphological maturation are missing. Biochemical ensemble measurements and structural analyses are hampered by the fact that HIV-1 release and maturation in tissue culture occur asynchronously between individual cells and between individual particles released from the same cell. We have established a method to synchronize HIV-1 proteolytic maturation in vitro with the aim to allow a more detailed analysis of the maturation process.

Methodology: Immature virions were prepared from cells treated with high concentrations of PR inhibitor and an inhibitor wash-out strategy was developed to induce proteolytic maturation of polyproteins within the assembled particles. Using this approach, we followed the production of mature Gag and Gag-Pol processing products over time. These data were correlated with analysis of viral infectivity, reverse transcriptase (RT) activity and virion morphology.

Results: Preparation of immature virions followed by inhibitor wash-out resulted in complete processing of Gag into its mature subunits with a 1/2 t1/2 of ~4 h under optimized conditions, suggesting that factors other than PR activity were limiting in this setup. Infectivity of ‘in vitro matured’ virions was detectably higher than that of the corresponding immature particles; recovery of infectivity was only partial, however, yielding low titers compared to mature virus prepared in the absence of inhibitor. Incomplete recovery of infectivity in spite of complete Gag maturation correlated with pronounced defects in Gag-Pol maturation and RT enzymatic activity.
Conclusions: We conclude that the complex process of HIV-1 maturation, occurring at high protein concentrations in a confined space, cannot be easily reconstituted within an already assembled immature virion. We therefore assume that tight temporal control between immature particle assembly and proteolytic processing is required to allow for correct polyprotein cleavage and arrangement of mature protein subunits. Further studies are directed towards elucidating this complex relationship.

181 Interplay of Cholesterol and Env Protein in the Lytic Deformation of HIV-1 by Peptide Triazoles
R Venkat Kalyana Sundaram1,2, Huiyuan Li3, Lauren Bailey4, A Rosemary Bastian1,2, Steven Wrenn5, Cameron Abrams6, Irwin Chaiken1
1Biochemistry and Molecular Biology, Drexel University College of Medicine, Philadelphia, PA, United States, 2School of Biomedical Engineering, Science and Health Systems, Drexel University, Philadelphia, PA, United States, 3Shared Research Facility, West Virginia University, Morgantown, WV, United States, 4Biochemistry, Drexel University College of Medicine, Philadelphia, PA, United States, 5Biochemistry, Drexel University College of Medicine, Philadelphia, PA, United States, 6Chemical and Biological Engineering, Drexel University, Philadelphia, PA, United States

Background: HIV-1 Env spike consists of gp120 involved in binding receptors and gp41 which is embedded in a lipid envelope that is mainly cholesterol (45-mol %) and involved in fusion. Envelope cholesterol affects infectivity of the virus and interacts with gp41. Our lab has developed peptide triazoles that inhibit gp120 binding to CD4 and CCR5/CXCR4 and cause leakage of capsid p24, from the viral lumen. Examining the effects of cholesterol on p24 release allows us to investigate lipid-protein interplay at the Env spike.

Methodology: Cholesterol was extracted from Bal.01 (HIV-1) and Vesicular Stomatitis Virus (VSV-G) spike pseudotyped viruses containing the Luciferase gene using methyl β-cyclodextrin (MβCD). Infectivity was detected by chemiluminescence from Luciferase expression in cells while p24 release and gp41 were measured by spinning virus and testing supernatant and pellet fractions respectively by ELISA. Fluidity was measured with Laurdan. Shed gp120 was detected from western blots. Morphological analysis was done on fixed virus by transmission electron microscopy (TEM). Cholesterol was quantified using Cholesterol Oxidase and the fluorescent Amplex Red dye.

Results: Initial depletion of viral membrane cholesterol strikingly enhanced both KR-13-induced p24 capsid protein leakage and infectivity and decreased virus size (TEM). Further depletion of cholesterol arrested both processes and caused complete shedding of gp120 but gp41 and the virus size remained intact and membrane fluidity increased though this wasn’t specific to HIV-1. Under similar conditions, the non-virolytic parent peptide HNG-156 did not induce p24 release and the VSV pseudotyped viruses did not see any enhanced infectivity.

Conclusions: Light cholesterol depletion enhances both KR-13 triggered p24 release and infectivity while heavy depletion arrest both processes, possibly due to shedding of gp120. While fluidity increases during cholesterol depletion, it is not specific to the HIV-1 spike. Correlated trends between infectivity and leakage during cholesterol depletion leading up to the gp120 shedding suggest lipid-protein interplay. To determine the mechanism of enhancement, we will test protease-treated viruses and Env mutations that disrupt the cholesterol interacting (CRAC), transmembrane, and cytoplasmic tail domains interacting with the lipid envelope. Together, this work will help determine the impact of lipid-protein interplay and define approaches to inactivate the virus.
182 Characterizing Novel N-Terminal Domains of APOBEC3G
Meiling R. May1, Ann M. Sheehy2
1College of the Holy Cross, Worcester, MA, United States, 2Biology, College of the Holy Cross, Worcester, MA, United States

Background: The human cytidine deaminase APOBEC3G (A3G) has been shown to exhibit antiviral function in the absence of its established catalytic function. A thorough molecular understanding of this deamination-independent mechanism is largely unknown.

Methodology: We sought out to characterize the A3G protein and identify key regions and domains related to its antiviral function. A library of mutants was constructed and these mutants were examined for antiviral function in a vif-deficient system. 293T cells were transiently cotransfected with proviral DNA and the mutant construct of interest. A3G and viral expression was verified by Western blotting. Viral particles were quantitated, normalized, and then used to infect TZM cells in a single round infectivity assay. Finally, virions were purified and assessed for A3G packaging. Concurrently, the catalytic activity of the mutants was examined using a Rifampicin based E. coli assay.

Results: We have identified two novel N-terminal domains that upon mutation confer a significant loss of antiviral function, but not an observable decrease in catalytic function.

Conclusions: These novel domains are quite interesting because they appear to play a significant role in antiviral function but not catalytic function. We are currently looking at the evolutionary conservation of these residues to determine whether these identified domains are in fact conserved or whether these domains fall within regions of the A3G protein that have been subjected to episodes of positive selection.

183 SLBP (Stem-Loop Binding Protein) Regulates the Expression of APOBEC3G
Ming Li, Lynne Tucker, Michelle Lally, Bharat Ramratnam
Alpert Medical School of Brown University, Providence, RI, United States

Background: Combining quantitative proteomics and functional analysis, we have recently demonstrated that SLBP restricts the integration and transcription of HIV-1. In lymphocytic cells, SLBP depletion leads to the concomitant decrease of the restriction factor APOBEC3G (apolipoprotein B mRNA-editing, enzyme-catalytic, polypeptide-like 3G). This decrease was observed at both the RNA and protein levels. Here, we sought to provide mechanistic insight into the novel SLBP/APOBEC3G relationship on the molecular level.

Methodology: First, using EpiQ™ chromat analysis, we compared promoter accessibility in lymphocytic cells under-expressing SLBP vs control samples. Then, chromatin Immunoprecipitation (ChIP) assay was employed to examine the binding affinity of specific transcription factors to APOBEC3G promoter regions. Finally, interferon PCR Arrays were performed to characterize potential molecules mediating interactions between SLBP and APOBEC3G.

Results: SLBP depletion led to a significant (p<0.05) decrease in chromatin accessibility of the APOBEC3G gene in CEM cells. Also under conditions of SLBP depletion, ChIP revealed less binding of SP1, a known APOBEC3G transcription factor, to the -150 to -50 (relative to transcription start site) APOBEC3G promoter region. Finally, using interferon α, β response RT² profiler™ PCR Arrays, SLBP depletion resulted in decreased level of IL15 (~10 fold), a known modulator for APOBEC3G.

Conclusions: The synergistic expression of SLBP/APOBEC3G is likely due to the combined effects of SLBP-induced chromatin accessibility and transcription factor binding affinities of the APOBEC3G promoter region. SLBP depletion also impacts the interferon pathway to modulate APOBEC3G levels indirectly. These results identify SLBP as a regulator of APOBEC3G.

184 Incomplete Apobec3G Neutralization by Vif Mutations Facilitates Evolution From CCR5 To CXCR4 Use
Claudia Alteri1, Matteo Surdo1, Patrizia Saccomandî1, Fabio Continenza2, Daniele Armeni1, Luca Caristi1, Anna Artese2, Francesca Ceccherini-Silberstein1, Carlo Federico Perino1, Valentina Sulcer1
1Department of Experimental Medicine and Surgery, University of Rome Tor Vergata, Rome, Italy, 2Istituto Nazionale per le Malattie Infettive “Lazzaro Spallanzani”, Rome, Italy

Background: Some Vif mutations favor incomplete Apobec3G (A3G) neutralization. In this setting, the increased burden of G-to-A mutations introduced by A3G can contribute to HIV genetic diversity and to HIV escape from antiretroviral drugs. Here, we investigate whether Vif mutations affect A3G capability to generate G-to-A mutations at V3 positions critical for CXCR4 usage and for HIV antigenic potential.

Methodology: The CCR5-using 81A-Vifwt and the 81A-VifK22E, 81A-VifE45G mutants with suboptimal activity against A3G were used to infect PBMC (experiments in triplicate). Frequency of G-to-A V3 mutations recovered from proviral DNA was analyzed by ultradeep sequencing (UDPS) at 7, 14, 21 days post infection (dpi). After shorah correction, mutations detected in both forward and reverse primers in >5 reads were considered. The False Positive Rate (FPR) by Geno2pheno was used to infer HIV tropism. To assess the correlation between Vif mutations and co-receptor usage, 769 paired HIV B subtype Vif and V3 RNA sequences from Los Alamos DB were analyzed.

Results: In PBMC, 81A-VifK22E and 81A-VifE45G show a decreased p24 production compared to p81A-Vifwt (mean log reduction=3.1 for K22E and 1.2 for E45G).

185 17β-Estradiol Protects Primary Macrophages Against HIV Through Induction of IFNα and APOBEC3A
Carley Tasker1, Jian Ding1, Mirco Schmolke2, Amariliz Rivera-Medina3, Adolfo García-Sastre2, Theresa Chang1
1Department of Microbiology and Molecular Genetics, Rutgers Biomedical and Health Sciences, Newark, NJ, United States; 2Department of Microbiology, Mount Sinai School of Medicine, New York, NY, United States; 3Department of Medicine, Rutgers Biomedical and Health Sciences, Newark, NJ, United States

Background: Estrogen has been shown to display a protective role against HIV/SIV transmission. The effect of estrogen on HIV infection of primary cells has recently been reported, but the mechanism underlying estrogen-mediated protection is not well defined. In this study, we examined the mechanism by which estrogen inhibits HIV infection in primary macrophages.

Methodology: Monocyte-derived macrophages (MDMs) were isolated from PBMCs of healthy human donors, and then treated with 17β-estradiol (E2) at different time points during HIV infection. Cells were infected with either replication-defective HIV pseudotyped luciferase reporter viruses for single-cycle infection assays or replication-competent viruses for multiple round infection assays. Level of viral infection was determined by measuring luciferase activity or by quantifying levels of HIV p24 in culture media by ELISA. E2-induced changes in gene expression of IFNs, SAMHD1, and the APOBEC family proteins were examined by RT-PCR analysis.

Results: E2 inhibited HIV replication in MDMs but not activated PBMCs or CD4+ T cells. Pretreatment of MDMs with E2 for 24 h was required to block HIV infection. E2 had no effect on HIV infection when MDMs were exposed to virus prior to E2 treatment. Investigation of the mechanism of E2-mediated HIV inhibition revealed E2 did not affect surface expression of CD4 and HIV co-receptors nor HIV attachment. E2 pretreatment also protected MDMs from infection by HIV reporter virus pseudotyped with VSV Env, which can enter cells independent of CD4 and HIV co-receptors. Quantitative PCR analysis of HIV reverse transcribed (RT) products showed E2 blocked the synthesis of late RT products. Investigation into the involvement of host restriction factors in E2-mediated HIV inhibition indicated that E2 induced gene expression of type I IFN and APOBEC3A in MDMs from multiple donors. Importantly, the anti-HIV activity of E2 was abolished in the presence of IFNα neutralizing antibody and was absent in bone marrow-derived macrophages from IFNα receptor deficient mice. Interestingly, HIV exposure suppressed E2-mediated type I IFN induction, suggesting that HIV could antagonize E2-mediated innate immune responses.

Conclusions: IFNα contributed to E2-mediated HIV inhibition in MDMs. E2 blocked HIV infection at the step of late reverse transcription. Induction of IFNα by E2 was associated with an increase in APOBEC3A but not APOBEC3G, APOBEC3F or SAMHD1. HIV can also antagonize E2-mediated type I IFN induction. Our study offers a better understanding of the interplay between HIV and E2-mediated immune responses that will provide insight into an effective strategy for HIV prevention.

186 Nuclear Import of APOBEC3F-Labeled HIV-1 Preintegration Complexes
Ryan C. Burdick, Wei-Shau Hu, Vinay K. Pathak
HIV Drug Resistance Program, National Cancer Institute, Frederick, MD, United States

Background: APOBEC3F (A3F) and APOBEC3G (A3G) are host factors that incorporate into virions and restrict HIV-1 replication. Although Vpr and integrase tagged with fluorescent proteins have been used to label viral particles, these marker proteins do not remain associated with PICs throughout replication. As a result, it has not been possible to visualize PICs in the nuclei of infected cells.

Methodology: We labeled HIV-1 particles with YFP-tagged APOBEC3 proteins and examined their association with preintegration complexes (PICs) in infected cells using quantitative confocal microscopy.

Results: We observed for the first time that transcription is not required for nuclear import of PICs. We also quantified association of cytoplasmic PICs with nuclear envelope (NE). In addition, we quantified the distance from the NE to the nuclear PICs to determine the nuclear penetration distance by PICs.

Conclusions: Using A3F-labeling as a novel tool to visualize PICs, we determined that 1) reverse transcription is not required for nuclear import of PICs, indicating that a viral core uncoating event associated with reverse transcription, and the central DNA flap that forms during reverse transcription, are not required for nuclear import; 2) viral core stability mutations dramatically reduce association of PICs with the nuclear envelope as well as diminish their nuclear import; and 3) most nuclear PICs remain close to the nuclear envelope and are not distributed throughout the nuclei.

By UDPs, no G-to-A mutations are detected in 81A-Vifwt-infected PBMC at each time point analyzed (0/14642 reads at 7dpi, 0/22084 at 14dpi, 0/23013 at 21dpi). G-to-A mutations at 2 V3 positions are observed in 81A-VifE45G-infected PBMC (prevalence from 0.03% [5/22448] to 0.06% [8/22448]). Conversely, a progressive enrichment of G-to-A mutations is detected in 81A-VifK22E infected PBMC (2.2% [373/16797] reads at 7dpi, 2.6% [278/10778] at 14dpi, 4.0% [812/20321] at 21dpi). G-to-A mutations account for >98% of the overall genetic variability, and occur at 6 V3 positions with 6/6 resulting non-synonymous (R9K, G15R, G24E, E25K, G28E/R, D29N). The presence of G24E and E25K strongly decreases the FPR (from 24.7 for wt to 6.8 for G24E and 5.0 for E25K), indicating CXCR4 usage acquisition. Consistent with this result, the introduction of G24E or E25K in B-subtype gp120 strongly increases CXCR4 N-terminus binding affinity for V3 (-40.1 kcal/mol for wt versus -510 kcal/mol for G24E and -522 kcal/mol for E25K). G15R resides in V3 crown proposed as vaccine target.

Finally, the analysis of paired V3 and Vif RNA sequences shows that the presence of at least one mutation in VifE22 and/or VifH45 correlates with increased prevalence of CXCR4 usage (44.8% versus 31.5% in Vifwt P=0.031).

Conclusions: A3G incomplete neutralization by single Vif mutations favors the generation of a proviral reservoir with an increased capability to use CXCR4 and to potentially escape neutralizing antibodies. This has implications for the success of CCR5 antagonist-based dual therapy and for immunological HIV control.

188A  Natural Resistance To HIV-1 by Select APOBEC3H Haplotypes

Eric W. Refsland1, Judd F. Hultquist1, Elizabeth M. Luengas1, Rachel Prosser2, Keith Henry1, Michael Emerman1, Reuben S. Harris1
1Biochemistry, Molecular Biology, and Biophysics, University of Minnesota, Minneapolis, MN, United States, 2Hennepin County Medical Center, Minneapolis, MN, United States

Background: HIV-1 pathogenesis requires neutralization of innate immune defenses. For instance, its viral infectivity factor (Vif) triggers the degradation of several members of the APOBEC3 family of DNA cytosine deaminases. Without Vif, HIV-1 succumbs to lethal mutagenesis inflicted by APOBEC3D, F, G, and H. Overexpression studies have shown that polymorphisms in human APOBEC3H encode proteins that differ widely in their expression levels.
and degrees of HIV-1 restriction. The distribution of APOBEC3H haplotypes is variable in human populations, but expression and activity of endogenous APOBEC3H protein in primary T cells has heretofore been difficult to measure. A major question is therefore whether the natural variation of endogenous APOBEC3H haplotypes in human populations influences HIV-1 infection in primary cells.

Methodology: Naïve CD4+ T lymphocytes were isolated from 24 donors and genotyped to determine APOBEC3H haplotype. Subsets of these donors with haplotypes that encode putatively stable and unstable APOBEC3H proteins were subjected to immunoblotting to compare endogenous protein levels and to ex vivo spreading infections to monitor susceptibility to HIV-1 infection. These experiments used HIV(IIIB) separation-of-function Vif alleles that were all fully able to counteract APOBEC3F and G, but either unable (F39V) or fully able (N48H, G60E, D61K, A62G, K63E) to degrade APOBEC3H haplotype II.

Results: APOBEC3H mRNA levels increased with T cell activation and further with HIV-1 infection regardless of haplotype. In contrast, the protein levels of APOBEC3H haplotype II (which encodes a stable protein) but not haplotype I or III (which encode unstable proteins) increased during the course of the infection. APOBEC3H from individuals heterozygous for haplotype II was efficiently packaged into virus-like particles (VLPs) from Vif F39V mutant virus, to a lesser degree in wild-type HIV, and was absent in VLPs from the Vif N48H, G60E, D61K, A62G, K63E mutant virus. Importantly, packaging of stable APOBEC3H caused a near total restriction of the Vif F39V mutant virus, a delay in replication kinetics of the wild-type virus, and had no effect on the Vif N48H, D61K, A62G, K63E mutant virus.

Conclusions: These data demonstrate that naturally occurring variants of APOBEC3H are expressed stably and capable of encapsidating and restricting HIV-1 replication in primary CD4+ T lymphocytes. Vif V39 exists in 25% of HIV-1 subtype B isolates suggesting a dynamic relationship between the evolution of Vif to antagonize APOBEC3H in populations in which some individuals express an active APOBEC3H and others do not. Future work will determine whether APOBEC3H haplotypes, along with viral variation in Vif, might explain some of the variation in HIV transmission or progression.

189 The Sphingosine-1-Phosphate Receptor 1 Dimerizes With CCR5 and Enhances HIV Infection

Background: CCR5 is a G protein-coupled receptor (GPCR). GPCR dimerization may result in a change in cell surface density, in ligand specificity and affinity and in the nature and intensity of the signaling pathway. Therefore, we looked for GPCR able to dimerize with CCR5 at the CD4 T cell surface.

Methodology: We identified by multi quantitative RT-PCR the GPCR coexpressed with CCR5 in circulating CD4 T cells. GPCR dimerization was evidenced by time-resolved FRET. Using HIV gene transfer vectors, we established two cell lines expressing or not the sphingosine-1-phosphate receptor 1 (S1P1). HIV infectibility by replicative and non-replicative HIV-1 strains was measured in both cell lines. The effect of S1P1 expression on LTR activation was studied in cells stably transfected with a reporter gene driven by HIV LTR and transduced with the S1P1 gene. S1P1 expression at the surface of primary cells was measured by flow cytometry. The effect of the S1P1 antagonist FTY720 was tested on SCID mice reconstituted with human peripheral blood mononuclear cells (PBMC) and infected with the HIV-1 R5 strain JR-CSF.

Results: We identified 250 GPCR coexpressed with CCR5 in circulating CD4 T cells. Among the GPCR the most expressed, we found that S1P1 dimerized with CCR5 at the cell surface. S1P1 coexpression resulted in a decrease in HIV-1 R5 virion entry, but not in cell to cell propagation. By contrast, S1P1 coexpression boosted LTR activation. Altogether these effects resulted in the increase in replicative HIV-1 R5 infection. We detected S1P1 at the surface of primary cells, in monocyte-derived dendritic cells, and FTY720 inhibited R5 infection in these cells. Moreover, this S1P1 antagonist inhibited HIV-1 R5 infection in a mouse model.

Conclusions: S1P1 dimerizes with CCR5 and its expression increases HIV-1 R5 replication. Consequently, an S1P1 antagonist inhibited R5 infection in vitro and in vivo. S1P1 might also impair the chemokine receptor function of CCR5, and vice versa.

190 Purinergic Receptor Antagonists as Potent Inhibitors of HIV-1 Infection by Blocking Early Entry
Talia H. Swartz, Anthony M. Esposito, Natasha D. Durham, Benjamin K. Chen
Icahn School of Mount Sinai, New York, NY, United States

Background: Human Immunodeficiency Virus (HIV-1) causes a chronic infection that can be controlled with antiretroviral medications. However, individuals living with HIV are still at increased risk of morbidity form cardiovascular disease, cancer, and neuropathy. Many of these sequelae are proposed to be due to chronic inflammation, however the mechanism has not been determined. Recent studies indicate that adenosine triphosphate (ATP) release and purinergic signaling is required for HIV-1 infection. Purinergic receptors are distributed through a wide variety of tissue types that detect extracellular ATP as a danger signal released from dying cells. Given this important role in immune cell signaling and viral infection, we have explored how these pathways are involved in transmission of HIV-1 virus from cell to cell through virological synapses. We propose that ATP is a key signaling molecule that links HIV-1 infection and HIV-associated inflammation.

Methodology: Our laboratory has devised molecular tools to study virus-host interactions through the use of fluorescent tags, allowing us to visualize discrete stages of infection. Using these infection assays, we are able to determine the step at which purinergic antagonists block cell-cell infection.
Results: Our data demonstrate that purinergic antagonists can potently block HIV-1 infection at an early stage of infection. We find that inhibitors are equally potent at blocking infection by cell-associated HIV and cell-free virus. This inhibition appears to occur before the initiation of viral membrane fusion. We are currently examining whether purinergic signaling is required for the recruitment of the viral co-receptors to the synapse to support viral fusion.

Conclusions: The results imply that co-receptor recruitment requires a purinergic signaling-dependent step to allow fusion. Our studies explore a novel mechanism of therapeutic targeting in HIV-1, that may also act on inflammatory and cell death pathways associated with chronic infection. We propose that targeting this pathway would represent a potent new form of antiretroviral therapy that may reduce both viral burden and associated inflammatory sequelae.

191 Optical Sorting of HIV-1 Reveal the Minimum Number of Spikes Required for Optimal Viral Infectivity
Wei Cheng
University of Michigan, Ann Arbor, MI, United States

Background: A fundamental question in HIV-1 biology is how many envelope spikes are required for viral infectivity. This number is also of great pharmacological interest because the lower this number is, the higher occupancy over the total number of functional spikes on a virion is required for entry inhibitors and neutralizing antibodies. The number of envelope spikes required for the optimal infectivity of HIV-1 is a difficult question to address without knowing the apparent heterogeneity of HIV-1 in their envelope content. How heterogeneity in viral envelope content may give rise to differences in viral infectivity is unknown. The distribution of the spike number and the total number of functional spikes per virion are both required for correct mathematical modeling of this process.

Methodology: In practice, the heterogeneity of HIV-1 envelope content can only be probed by using a technique that permits study of individual virions at single-molecule level so that each virion can be quantitated for their protein composition, preferably under native conditions. Here we developed a technique of this kind, which we termed, ‘virometry’, that was based on optical manipulation of a dielectric particle in liquid. This technique permits multi-parameter analysis of individual HIV-1 virions in culture media under native conditions, and allowed us to directly address the heterogeneity among virions in their protein compositions down to single-molecule level.

Results: By using fluorescent antibody against gp120, we show that the quantity of gp120 proteins per virion varies over one order of magnitude despite the fact that all the viruses were derived from a single clone, which yields substantial heterogeneity in viral infectivity. By characterizing a series of HIV-1 with different contents of envelope glycoproteins, we reveal a clear nonlinear dependence of HIV-1 infectivity on envelope glycoprotein content.

Conclusions: Model-independent analysis of our data revealed that HIV-1 envelope spikes function cooperatively to mediate HIV-1 infection, and a minimum of two envelope spikes is required for optimal viral infectivity (Supported by NIH 1DP2OD008693-01; WC).

192 Application of an HIV Entry Assay To Identify HIV Target Cells in the Female Genital Tract
Vineet R. Joag
University of Toronto, Toronto, ON, Canada

Background: The HIV pandemic disproportionately affects women, with the majority of new infections occurring through vaginal sex. The cellular targets of HIV infection in the female genital tract (FGT) are poorly defined, although virus replication in mucosal CD4+ T cells is important and correlates of 4β7- and 4β7+ CD4 T cells are preferential targets of CCR5-dependent HIV entry, but finds no preferential targeting of 4β7+ CD4 T cells. This assay has potential as an intermediate endpoint to assess the impact of clinical interventions on the risk of HIV acquisition.
193  Early Non-Mac-Tropic HIV-1 R5 Envs Efficiently Trans-Infect T Cells and Infect Ectocervices

Paul J. Peters1, Olivia O’Connell1, Thomas Musch1, Maria Paz Gonzalez-Perez2, Tiffany Moore-Simases3, Cynthia Berdrey4, Paul R. Clapham1

1Molecular Medicine, University of Massachusetts Medical School, Worcester, MA, United States; 2National Cancer Institute, Bethesda, MD, United States; 3Obstetrics & Gynecology, UMass Memorial Medical Center, Worcester, MA, United States; 4Emory Vaccine Center, Atlanta, GA, United States

**Background:** Non-mac-tropic HIV-1 R5 viruses are preferentially transmitted and persist in immune tissue even in AIDS patients who carry highly mac-tropic variants in the brain. Non-mac-tropic R5 Envs require high levels of CD4 for infection contrasting with highly mac-tropic Envs, which interact more efficiently with CD4 and can infect cells expressing low CD4. Here, we investigated whether transmitted/founder (T/F), early and late non-mac-tropic R5 Envs mediated more efficient trans-infection of primary CD4+ T-cells and/or infection of ectocervical explant cultures compared to highly mac-tropic R5 Envs.

**Methodology:** We tested non-mac-tropic R5 Envs identified as transmitter/founder (T/F) and others derived from the acute or late stages of infection. We compared these Envs with highly mac-tropic R5 Envs from late disease. We used Env+ pseudovirions that carried a GFP reporter gene to measure trans-infection of CD4+ T-cells after virus transfer from monocyte-derived dendritic cells (MDDCs) and infection of ectocervical explant cultures.

**Results:** T/F and acute stage R5 Envs conferred low or background levels of macrophage infection. Infectivity was similar to that mediated by non-mac-tropic R5 Envs from late disease and up to 3 orders of magnitude lower than highly mac-tropic R5 Envs from brain tissue. In contrast, non-mac-tropic and highly mac-tropic R5 Envs mediated similar levels of infectivity for CD4+ T-cells following capture and transfer by MDDCs. Infection of ectocervical explants varied for both non-macrophage-tropic and highly mac-tropic R5 envelopes but were not significantly different. Curiously, T/F Envs conferred lower infection of ectocervical explants compared to highly mac-tropic Envs. Cells infected in ectocervical explants by the highly mac-tropic R5 Bal Env were almost exclusively CD4+ T-cells.

**Conclusions:** T/F, acute and late stage non-mac-tropic R5 Envs mediated efficient infection of primary CD4+ T-cells via immunological synapses. Highly mac-tropic R5 Envs from late disease do not confer higher levels of infectivity for primary T-cells following synaptic transfer despite their enhanced ability to interact with CD4.

T/F and acute stage R5 Envs confer infection of ectocervical explants but are not more tropic for this tissue compared to non-mac-tropic or highly mac-tropic Envs from late disease.

Supported by NIH R01 AI089334, MH064408, AI58706 and P01 AI082274.

194  Transmitter as Compared To Recipient Envelopes Confer Greater Replication and α4β7 Utilization

Victor Pena-Cruz1, Behzad Etemad1, Nikolaos Chatziandreou1, Shannon Stöck1, Steven J. Reynolds2, Oliver Layendecker2, Ronald H. Gray3, David Serwadda4, Thomas C. Quinn3, Manish Sagar1

1Boston University, Boston, MA, United States; 2College of the Holy Cross, Worcester, MA, United States; 3The Johns Hopkins University, Baltimore, MD, United States; 4Makerere University School of Public Health, Kampala, Uganda

**Background:** Newly infected individuals generally acquire only a limited number of viruses from chronically infected partners with diverse HIV-1 variants. The biological mechanism for this selection remains uncertain.

**Methodology:** We identified 9 transmission pairs enrolled in the Rakai community cohort study in Uganda. Full-length HIV-1 envelopes generated from pooling multiple bulk PCRs were incorporated into a HIV-1 backbone to create replication competent recombinant viruses. Viruses were examined for receptor usage, gut homing receptor, α4β7, binding, sensitivity to entry inhibitors, and replication capacity in various primary cell cultures, such as CD4+ T cells, immature and mature monocyte-derived dendritic cell (MDDC) - CD4+ T cell co-cultures, Langerhans cells (LC) - CD4+ T cell co-cultures and CD4+ T cells expressing high levels of α4β7 integrin. Significantly higher replication and receptor tropic characteristics and recipient to transmitter ratios were compared among the partners in a relationship using the Wilcoxon rank-sum test and one-sample Wilcoxon signed-rank test respectively.

**Results:** The newly infected partner was sampled a median of 70 days (range 17 - 324 days) after estimated infection while all transmitters had HIV-1 for at least 2 years prior to estimated transmission. Recipient compared to the transmitter envelopes showed no significant difference in their sensitivity to entry inhibitors (p > 0.05). Virus with the transmitting partner as compared to recipient envelopes replicated more efficiently in CD4+ T cells (p = 0.03), mature MDDC - CD4+ T cell co-cultures (p < 0.001), Langerhans cells (LCs) - CD4+ T cell co-cultures (p = 0.02), and CD4+ T cells expressing high levels of α4β7 (p = 0.01), and demonstrated greater binding to α4β7 high / CD8+ T cells (p = 0.04). Transmitter versus recipient envelope virus phenotypic differences were not always consistent among the primary cells obtained from a minimum of 4 different blood or skin donation volunteers. There was a non-significant negative correlation between replication in α4β7 high CD4+ T cells and days post-infection suggesting that if these are the transmission phenotype they are lost relatively early after acquisition.

**Conclusions:** Envelopes found in recently infected subjects as compared to the corresponding transmitting partner have significantly lower replication capacity in primary cells and decreased binding to the α4β7 integrin. Even though the majority of recently infected subjects were not sampled soon after estimated acquisition, our results suggest that if enhanced infectivity and/or greater α4β7 binding are transmission phenotypes then viruses with these characteristics are selected against early after acquisition and subsequently enriched during the chronic phase of disease.
195 Differences in HIV Receptor Activity of CXCR4 Isoforms: Consequences for X4 Strains Emergence
Charline Duquenne1, Christina Psomas2, Sandrine Gimenez1, Marie-Josée Carles2, Claudine Barbaut3, Jean-Philippe Lavigne3, Albert Soto1, Jacques Reynes4, Vincent François5, Pierre Corbeau1
1Institute of Human Genetics, CNRS, Montpellier, France, 2Infectious Diseases, University Hospital, Montpellier, France, 3Microbiology, University Hospital, Nîmes, France, 4Infectious Diseases, University Hospital, Nîmes, France

Background: Two CXCR4 isoforms have been described in humans, CXCR4-A and CXCR4-B, corresponding to an unspliced and a spliced mRNA, respectively. In this study we analyzed the expression of both isoforms, and their functions as HIV coreceptors and chemokine receptors.

Methodology: To this aim, using HIV gene transfer vectors, we established two cell lines expressing each isoform. HIV infectibility by replicative and non-replicative X4 strains was measured in both cell lines, and the amount of early reverse transcripts was quantified as a marker of viral entry. The capacity of both cell lines to support R5 to X4 switch was studied in vitro. Chemotaxis assays were performed. Expression of the two forms of CXCR4 mRNA was evaluated by specific RT-PCR. R5/X4 genotype was defined in HIV-infected persons by determining the False-Positive Rate (FPR) score calculated by the Geno2Pheno algorithm using the sequence of the V3 region of the envelope.

Results: We showed that CXCR4-B, but not CXCR4-A, mediates an efficient HIV-1 X4 entry and productive infection. Yet, the chemotactic activity of CXCL12 on both isoforms was similar. In vitro infection with an R5 strain increased CXCR4-B : CXCR4-A mRNA ratio in peripheral blood mononuclear cells (PBMC), and this ratio correlated with HIV RNA plasma level in R5-infected individuals. In addition, the presence of the CXCR4-B isoform favored R5 to X4 switch more efficiently than CXCR4-A in vitro. Moreover, the capability of circulating HIV-1 strains to use CXCR4, determined after the FPR, was linked to the predominance of CXCR4-B over CXCR4-A expression in PBMC. Finally, we achieved a specific siRNA-mediated knockdown of CXCR4-B.

Conclusions: CXCR4 isoforms present with similar chemokine receptor but different HIV coreceptor capabilities. Our data support the hypothesis that HIV-R5 infection favors CXCR4-B expression over that of CXCR4-A, a phenomenon that could facilitate R5 to X4 switch. We also established a proof of concept for a possible gene therapeutic approach aimed at specifically blocking the HIV coreceptor activity of CXCR4-B.

196 Defining Interactions of HIV With Rectal Epithelial Barriers and Rectal Mucus
Luis M. Barcena1, Mirih Dinh1, Peter A. Anton1, Thomas J. Hope1
1Northwestern University Feinberg School of Medicine, Chicago, IL, United States, 2UCLA, David Geffen School of Medicine, Los Angeles, CA, United States

Background: A major mode of HIV transmission is through receptive anal intercourse with an infected individual. How HIV interacts with the rectal mucosal barriers composed of columnar epithelium covered with a protective layer of mucus has yet to be defined. Therapies that affect the rectal mucosal barrier may play an important role in HIV prevention strategies. We sought to investigate how HIV interacts with the rectal epithelium and the role rectal mucus plays in these interactions using a human rectal biopsy model, in vivo challenges in rhesus macaques, and studies of rectal mucus.

Methodology: We enrolled 5 HIV seronegative adults undergoing routine screening colonoscopy. 5 rectal biopsies were obtained per patient and transferred to our lab. Tissues were inoculated with a photoactivatable GFP Vpr HIV-1 for 1, 2 and 4 hours. Samples were also treated with a mucolytic enzyme, neuraminidase. In vivo challenges used the same virus. Animals were necropsied at 4 hours post-rectal exposure. The tissue was snap frozen in OCT, sectioned, and epifluorescent deconvolution images were taken with a Delta Vision RT system and analyzed with SoftWorx software.

Results: Rectal biopsies incubated at 1 and 2 hours with an intact mucus layer were associated with the highest number of virions, most of which were seen trapped in the mucus. Accordingly, explants treated with neuraminidase (which decreased the amount of mucus at the surface) did not show the associated trapping of HIV. HIV penetration of the rectal mucosal barrier was observed as early as after 1 hour of incubation. Penetration was more commonly seen in areas where epithelial integrity was apparently compromised. Similar results were seen after in vivo challenge validating the short-term explant studies.

Conclusions: These findings suggest that the mucosal barrier of the rectal compartment can influence the ability of HIV to penetrate this barrier to reach underlying target cells. The protective layer of mucus clearly plays an important role in barrier function. The disruption of the barrier allows increased interaction with underlying target cells. Inflammatory conditions that increase transmission are likely influencing the mucus barrier. A better understanding to the interaction of HIV with the rectal mucosal barrier will facilitate future prevention strategies to decrease HIV acquisition.

Session P-A7 Poster Session

197LB Platelet Factor 4 Oligomeric State Correlates With Antiviral Activity
Zahra F. Parker1, Ann Rux2, Fang-Hua Lee1, Amber Riblett1, Mortemer Ponz2, Bruce Sachais4, Robert Doms5
1Microbiology, University of Pennsylvania, Philadelphia, PA, United States, 2Pathology, University of Pennsylvania, Philadelphia, PA, United States, 3Hematology, The Children’s Hospital of Philadelphia, Philadelphia, PA, United States, 4Pathology and Laboratory Medicine, Hospital of the University of Pennsylvania, Philadelphia, PA, United States, 5Infectious Diseases, University Hospital, Nîmes, France

Background: The platelet-derived chemokine platelet factor 4 (PF4) promotes blood coagulation and serves as a chemoattractant for immune cells. Recently PF4 has been shown to inhibit HIV-1 infection in vitro at concentrations less than 0.5μM. However, despite plasma and local tissue concentrations of PF4 ranging from 0.25nM to 10μM, HIV is able to successfully replicate and escape the inhibitory effects of PF4 in vivo. The mechanism of this discordance remains unclear. Here, we demonstrate that the inhibitory effects of PF4 are limited to a narrow concentration range, corresponding to the predominance of a monomeric state. At concentrations of greater than 1μM, PF4 multimerizes and viral infection in vitro is enhanced.
**Methodology:** Wildtype and mutant PF4s with distinct oligomeric properties were tested for their ability to inhibit viral infection in vitro. We examined the ability of HIV-1 pseudotyped viruses expressing the envelope glycoprotein from CCR5- and CXCR4-using HIV-1, MLV, influenza (H5N1), and VSV-G to infect cell lines and primary human CD4+ T cells in the presence of increasing amounts of either wildtype or mutant PF4. Infection data was compared using t-tests and Fisher’s exact tests.

**Results:** All HIV-1 Envs (n = 24) were inhibited (mean = 65%, SD = 30) by PF4 (<1μM) independent of coreceptor tropism. VSV-G and MLV were also inhibited, while influenza H5N1 pseudoviruses were resistant to PF4. Surprisingly, the inhibitory effects of PF4 waned at concentrations greater than 1μM, above which viral entry was enhanced. Moreover, at concentrations above 1μM of the PF4 mutant K50E, which disrupts the formation of tetramers, we observed approximately 70% inhibition of viral infection. This was in contrast to the 2- to 5-fold enhancement observed with the wildtype PF4 at the same concentration. Chemical crosslinking was used to confirm differences in the oligomeric state of the wildtype and mutant PF4s at the different concentrations tested.

**Conclusions:** While PF4 inhibits diverse HIV-1 strains in its monomeric state, we demonstrate that it enhances infection when it exists as a tetramer. Since PF4 exists in a dynamic equilibrium, with tetramers predominating at physiologic levels, we conclude that the in vitro inhibitory effects of PF4 are less likely to predominate at physiologic PF4 concentrations. A more detailed understanding of how PF4 modulates viral infection may reveal new insights into virus-chemokine interactions that could inform novel therapeutic interventions.

---

**198 CRM-1: A Critical Regulator of HIV Replication in a Quest Towards a Small Animal Model for HIV**

**Hila Elinav**¹, Yuanfei Wu², Ayse Coskun², Katarzyna Hryckiewicz³, Iris Kemler³, Yani Hu³, Bing Hao³, Choukri Ben Mamoun⁴, Eric Poschla³, Richard Sutton²

¹Clinical Microbiology and Infectious Diseases, Hadassah Hebrew University Medical Center, Jerusalem, Israel, ²Infectious diseases, Yale University, New Haven, CT, United States, ³Department of Molecular Medicine, Mayo Clinic, Rochester, MN, United States, ⁴Infectious Diseases, Yale University, New Haven, CT, United States

**Background:** Combination anti-retroviral therapy has markedly improved the prognosis of individuals living with HIV, yet treatment is not curative, and is often limited by major side effects, emerging viral resistance, drug interactions, and high costs. Furthermore, pathogenesis studies, vaccine development and drug testing are severely hampered by lack of small animal models for HIV infection. In the mouse, there are several blocks to HIV replication. Although some of the obstacles were identified, the underlying molecular mechanisms of this barrier remain poorly understood and have not fully characterized. The aim of this work was to identify factors that augment HIV replication in murine cells and to elucidate their mechanism of action.

**Methodology:** Using an experimental system that allow quantification of infectious virus production in murine cell, we assessed the effect of expression of panel of human proteins upon HIV production.

**Results:** The expression of human CRM-1 SRp-40 and SRp55 increased HIV pseudotyped particles in murine cells and the co-expression of hCRM-1 and SRp40 had a more than additive effect. Human CRM-1 increased unspliced/spliced HIV RNA ratio, mildly augmented the levels of intracellular Gag protein while the infectious viral production was disproportionally increased. Using human and murine CRM-1 chimeras and hCRM-1 mutants we mapped the functional domain of hCRM-1 to three amino residues. This functional region is different from a domain that was previously identified as the binding groove of hCRM-1.

**Conclusions:** CRM-1 has a key role in HIV production, and the murine protein has a loss of function. Identifying a new functional domain in this protein suggests the involvement of other factors interacting with CRM-1 that might have an effect upon HIV production. Elucidating these interactions can assist in a) further understanding of mechanisms of murine resistance to HIV infection. b) Identification of new host-related therapeutic targets for HIV. c) Establishment of the first small animal model of HIV infection, allowing for facilitated study and drug testing of this common devastating disease.

**199 Analyses of the Sequence-Function Relationships Among HIV-1 Vpr, SIVagmVpr, and SIVmacVpx**

**Ana Beatriz DePaula-Silva**, Patrick A. Cassidy, Vicente Planelles

Pathology, University of Utah, Salt Lake City, UT, United States

**Background:** Lentiviral accessory proteins are known for their ability to counteract host immune responses. Despite the sequence similarity shared by Vpr and Vpx, and the fact that both proteins hijack the cellular CRL4 E3 ligase via DCAF1 interaction, they have very different functions. Vpx causes degradation of cellular SAMHD1, making viral replication in myeloid cells permissive. Vpr is the least well-understood accessory protein. Vpr causes G2-to-M arrest in infected cells but the mechanism is not clear. On the other hand, Vpx does not arrest cells and SIVagmVpr causes G2 arrest in AGM cells but not in human cells. In order to understand the domains required for G2 arrest function and SAMHD1 degradation, we generated a variety of chimeras based on the published NMR structure for HIV-1 Vpr. HIV-1 Vpr is composed by a bundle of three alpha helices, flanked by amino and carboxy-terminal unstructured regions, connected by short flexible loops.

**Methodology:** To map the functionally relevant domains in HIV-1 Vpr, SIVmacVpx and SIVagmVpr that confer the differential abilities to interact with host immune responses, we generated 7 chimeras where we exchanged domains between HIV-1 Vpr and SIVagmVpr and 4 additional chimeras between HIV-1 Vpr and SIVmacVpx. We then tested the abilities of these chimeras to induce G2 arrest in human cells and to cause degradation of hSAMHD1 and agmSAMHD1

**Results:** We found that the N-terminus unstructured region of SIVmacVpx is not sufficient to target cellular SAMHD1 for degradation. Surprisingly, the exchange of the unstructured C-terminus region of SIVagmVpx to the HIV-1 Vpr confers to SIVagmVpr the species-specificity domain required to target the human cellular protein, allowing the SIVagmVpr to induce G2 arrest in human cells.
Conclusions: Vpr and Vpx lentiviral proteins are examples of modular viral proteins where functions can be associated with specific domains. Genetic exchange of these domains is a powerful method to analyze the contribution of such domains to protein function and allows for analysis of evolutionary pressures and their impact on sequence variation.

Elevated Expression of Anti-HIV-1 Restriction Factors in Effector Memory CD4+ T Cells In Vivo
Mohamed Abdel-Mohsen1, Xiutao Deng2, Rui Andre Saraiva Raposo3, Teri Liegler1, Elizabeth Sinclair1, Rebecca Hohl1, Douglas F. Nixon1, Joseph K. Wong2, Steven G. Deeks1, Satish K. Pillai1
1University of California, San Francisco, San Francisco, CA, United States, 2Blood Systems Research Institute, San Francisco, CA, United States

Background: Recent observations suggest that there may be less viral outgrowth from effector memory than central memory CD4+ T cells from ART-suppressed individuals, despite similar levels of HIV-1 DNA in these cellular subsets. This may be driven by cell-intrinsic factors suppressing viral production, and/or the disproportionate presence of replication-incompetent HIV-1 variants in effector memory cells. In this study, we compare restriction factor gene expression patterns between effector memory and central memory CD4+ T cells from individuals of different HIV-1 disease states, to address the hypothesis that host restriction mechanisms suppress viral outgrowth in effector memory CD4+ T cells.

Methodology: Flow-based sorting was used to isolate central and effector memory populations in 20 individuals enrolled in the SCOPE cohort (5 ART suppressed, 5 elite controllers, 5 non-controllers, and 5 uninfected individuals). We implemented a custom real-time PCR array to measure the mRNA expression of 35 established anti-HIV-1 restriction factors in T cell subsets. To represent overall cellular anti-HIV-1 restriction capacity, we defined a CuRe (Cumulative Restriction) score as the cumulative fold-difference in restriction factor expression with respect to a control individual. Unpaired t tests were used to compare gene expression levels.

Results: CuRe scores were significantly higher in effector memory as compared to central memory CD4+ T cells in HIV-1-uninfected individuals (p=0.008), and in HIV-1-infected individuals (p=0.009). 15 out of 35 anti-HIV-1 restriction genes were significantly elevated in effector memory CD4+ T cells from HIV-1-infected individuals: APOBEC3C, APOBEC3D, APOBEC3G, APOBEC3H, BRD4, CRY9, IFITM2, p21, RTF1, schlafen 11, TRIM11, TRIM14, TRIM19, TRIM21, and TRIM26. TRIM32 was the only restriction factor that was significantly elevated in central memory CD4+ T cells. Within the ART-suppressed group, CuRe scores were significantly higher in effector memory CD4+ T cells (p=0.034). In particular, five restriction factors were elevated: APOBEC3G (p=0.04), APOBEC3H (p<0.0001), TRIM11 (p<0.015), TRIM19 (p=0.0002), and TRIM26 (p=0.038).

Conclusions: Expression data from our exploratory analyses of sorted T cell subsets indicate that enhanced host restriction factor expression may contribute to the reduced viral outgrowth observed in effector memory CD4+ T cells. Restriction factors that are elevated in ART-suppressed individuals include particular TRIM family members that attack HIV-1 at the post-integration phase, and APOBEC3 deaminases that hypermutate HIV-1 genomes. These observations warrant validation using larger sample sizes and sequence analysis of proviral DNA from isolated T cell subsets.

TRIM5alpha Determinants for the Activation of Innate Immunity
Marie-Édith Nepeu-Traversy, Lionel Berthoux
Medical Biology, UQTR, Trois-Rivières, QC, Canada

Background: Specific recognition of incoming viral capsids by the anti-retroviral factor TRIM5α disrupts progression of the virus life cycle and also triggers the induction of an antiviral state involving the activation of transcription factors NF-κB and AP-1. Additionally, TRIM5α promotes the formation of K63-linked ubiquitin chains which are thought to be important for innate immunity activation. These functions can also be revealed by over-expressing TRIM5α in the absence of virus, providing a convenient experimental model. A RING zinc-binding motif with E3 ubiquitin ligase activity is found at the N-terminus of TRIM5α and is involved in both the direct inhibition of incoming retroviruses and in innate immune activation. Other TRIM5α motifs were found to be related to the sumoylation pathway, specifically a putatively sumoylated lysine (lysine 10) just upstream of the RING domain, and putative SUMO interaction motifs (SIMs) in the C-terminal PRYSPRY domain which also determines interaction with capsid. Here, we analyzed the role of lysine 10 and the SIMs in the activation of innate immunity by TRIM5α.

Methodology: We searched for novel SIMs in Rhesus macaque TRIM5α by computational analysis. Lysine 10, the RING domain and the various SIMs of the macaque TRIM5α PRYSPRY domain were mutated and the impact on HIV-1 restriction and on markers of innate immunity activation was measured using specific antibodies for K63-linked ubiquitin and reporter plasmids for NF-κB and AP-1 activation. Co-localization of TRIM5α and nuclear SUMO-1 was observed by IF microscopy.

Results: As expected, mutating the RING domain completely abrogated activation of NF-κB, AP-1 or the generation of K63-linked ubiquitin. Mutating Lysine 10 significantly decreased the activation of NF-κB and AP-1, and reduced the generation of K63-linked ubiquitin. The K10R mutation also caused an increase in TRIM5α self-ubiquitination, unlike mutations in the RING domain which also abrogate this activity. We identified a novel putative SIM motif in PRYSPRY, which we named SIM4. Mutating SIM4 strongly decreased activation of NF-κB while having no effect on the capacity of TRIM5α to trigger the formation of K63-linked ubiquitin chains. Mutations in both lysine 10 and SIM4 decreased the transient nuclear association of TRIM5α with SUMO-1.

Conclusions: Motifs in TRIM5α that are linked to the sumoylation pathway are important for the efficient activation of innate immunity. Lysine 10 modulates the ubiquitin ligase activity of the nearby RING domain to promote K63-linked ubiquitination, while SIM4 has no effect on K63-linked ubiquitin but is nonetheless important for the activation of NF-κB. Thus, we have identified motifs of TRIM5α that differentially modulate activation of innate immunity.
202 HIV-1 Vpu Antagonizes Macaque and Chimpanzee BST-2 Through Cytoplasmic Domain Interactions
Takeshi Yoshida1, Yoshiho Koyanagi2, Hirofumi Akari1, Klaus Strebel2
1Center for Human Evolution Modeling Research, Primate Research Institute, Kyoto University, Inuyama, Japan, 2Laboratory of Molecular Microbiology, National Institute of Allergy and Infectious Diseases, NIH, Bethesda, MD, United States, 3Laboratory of Viral Pathogenesis, Institute for Virus Research, Kyoto University, Kyoto, Japan

Background: The HIV-1 Vpu protein enhances the release of viral particles from infected cells by interfering with host factor BST-2/tetherin, which tethers nascent virions to the cell surface and inhibits virus release. Previous work demonstrated that HIV-1 NL4-3 Vpu can target human BST-2 (huBST-2) but not monkey BST-2 (moBST-2), suggesting a species-specific activity. However, we found that Vpu of a clinical HIV-1 isolate (DH12) counteracted huBST-2 as well as moBST-2. We also found that an NL4-3 Vpu mutant carrying transmembrane (TM) domain of DH12 Vpu (Vpu tmDH12) could antagonize moBST-2. Interestingly, SIVcpz-encoded Vpu neither antagonizes chimpanzee BST-2 (chBST-2) nor huBST-2. We hypothesized Vpu’s ability to antagonize BST2 is directly linked to its ability to bind BST-2.

Methodology: We assessed the physical interaction of Vpu with BST-2 using a live cell protein-protein interaction assay based on bimolecular fluorescence complementation (BiFC). We transfected 293T cells with BiFC-tagged moBST-2 and BiFC-tagged NL4-3 Vpu or Vpu tmDH12 and quantified the BiFC signal using flow cytometry as a measure of how efficient two molecules are interacting. At the same time we assessed functional antagonism of BST-2 by quantifying released virus in a TZMbl-based infectivity assay or by pulse/chase analysis.

Results: NL4-3 Vpu interacted with moBST-2 almost as efficiently as Vpu tmDH12 suggesting that physical interaction of Vpu with BST-2 is not sufficient for functional antagonism. Our results also suggest that Vpu interaction with moBST-2 might involve domains other than, or in addition to, the TM domain. In fact, we found that HIV-1 Vpu interacts with moBST-2 through a DDIWK motif in the cytoplasmic domains of moBST-2 while it interacts with huBST-2 via its TM domain. We found that Vpu tmDH12 antagonized moBST-2 but not moBST-2 mutant lacking DDIWK motif presumably because of a lack of cytoplasmic domain interaction. Our analysis of SIVcpz Vpu revealed that it neither interacted with chBST-2 nor huBST-2 which may explain why it fails to antagonize them. Interestingly, transfer of the NL4-3 Vpu cytoplasmic domain into SIVcpz Vpu was sufficient to allow interaction with chBST-2 and to allow SIVcpz Vpu to functionally antagonize chBST-2.

Conclusions: Taken together, our data reveal that domains required for functional interaction of Vpu with BST-2 and BST-2 are not limited to the TM domains. Indeed, interaction of Vpu with moBST-2 or chBST-2 occurs primarily via their cytoplasmic domains. This interaction is necessary but not sufficient for functional antagonism, which also depends on determinants encoded by the Vpu TM domain.

203 Investigating the Requirement of a NOD-Like Receptor for Early HIV Replication
Manja Burggraf1, Prashant Jain1, Crystal Shih1, Nicole Easley1, John Marlett1, John A. Young1, Sumit K. Chanda2, Renate Koenig3
1Host-Pathogen-Interactions, Paul-Ehrlich-Institute, Langen, Germany, 2Sanford-Burnham Medical Research Institute, La Jolla, CA, United States, 3The Salk Institute, La Jolla, CA, United States

Background: Human Immunodeficiency viruses rely on host-encoded proteins to facilitate their replication. A previous genome-wide siRNA screening approach (Koenig et al., 2008) resulted in the identification of NLRX1 as a host cellular protein required for early stages of HIV-1 replication. NLRX1 is a member of the Nod-like Receptor family, which collectively play critical roles in innate immune responses. Thus, our data provide a compelling link between an innate immune signaling receptor, NLRX1, and HIV-1 replication.

Methodology: HIV-1 luciferase reporter viruses pseudotyped by VSV-G and HIV-1 replication competent WT viruses were used to investigate the effect of silencing of NLRX1 on replication efficiency in various cell lines and primary cells. In addition, we assessed the infectivity levels of pseudotyped particles with amphotropic envelope using a pH-independent entry route and mapped the stage of viral inhibition by real-time quantitative PCR. Effects on IRF3-dependant target gene expression were assessed by quantitative PCR and IFN ELISA.

Results: We first validated NLRX1 as a factor required for early-stage HIV infection in various cell lines, including 293T, HeLa and more physiological relevant cells, THP1, Jurkat cells and primary macrophages. NLRX1-inhibition resulted in a failure to initiate reverse transcription and was independent of the viral entry route. NLRX1 was recently reported to act as a negative regulator of mitochondrial antiviral immunity, through binding and inhibition of MAVS, an essential mediator of the RIG-I and IFN-β antiviral response. Based on the hypothesis that the inhibition of NLRX1 may render the innate surveillance machinery competent to respond to HIV infection, we sought to determine the effects of NLRX1 depletion upon IFN3 target gene transcription. We observed that ISG54, IFN-β and IL-6 was robustly induced upon infection with HIV in NLRX1-depleted cells, but importantly, NLRX1 silencing did not induce these genes in the absence of HIV.

Conclusions: These data suggest that restriction of HIV is not due to a generalized and persistent hyper-activation of an innate immune state in NLRX1-depleted cells. In conclusion, we demonstrate the requirement of NLRX1 for early HIV-1 replication. We are currently investigating the molecular basis of NLRX1 dependency in early stage HIV replication.

204 ITIH4: A Cellular Factor Targeted by HIV-1 Vpr
Steven Santos1, Yong-Hui Zheng2, Michael Bukinsky3
1The George Washington University, NW Washington, DC, United States, 2Michigan State University, East Lansing, MI, United States

Background: The immune system has a multitude of innate immune factors that work to counteract many different viruses. For HIV-1, such factors include APOBEC-3G, Tetherin (BST-2), SAMHD1, and, in the case of non-human primates, Trim5α. However, lentiviruses have evolved accessory proteins to counteract most, if not all of these factors. Such accessory proteins include HIV-1 Vif which degrades APOBEC-3G, HIV-1 Vpu and SIV Nef which reduce cell surface expression of Tetherin, and SIV Vpx which degrades SAMHD1. Interestingly, HIV-1 Vpr, an orthologue of SIV Vpx, does not degrade SAMHD1, and no cellular target for VPR has been identified as yet.
Transmission Networks

205 Ongoing HIV-1 Subtype B Transmission Networks in the Netherlands

Daniela Bezemer1, Oliver Ratmann2, Ard van Sighem3, Bas E. Dutt4, Nuno Faria4, Rob van den Hengel5, Luuk Gras6, Peter Reiss6, Frank de Wolf7, Christophe Fraser8, ATHENA observational cohort
1Research, HIV Monitoring Foundation, Amsterdam, Netherlands, 2Imperial College, London, United Kingdom, 3Centre for Molecular and Biomolecular Informatics, Nijmegen, Netherlands, 4University of Oxford, Oxford, United Kingdom

Background: The HIV-1 epidemic amongst men having sex with men (MSM) in the Netherlands has been shown to be resurgent despite the widespread use of effective combination antiretroviral therapy (cART). This epidemic is dominated by HIV-1 subtype B. In this study, using phylogenetic analysis of HIV-1 subtype B polymerase sequences, we identify the transmission networks that constitute the epidemic.

Methodology: As of June 2011, the ATHENA database contained polymerase sequences from 5,852 subtype B infected patients in the Netherlands. For every sequence, the 10 most similar sequences were selected from the Los Alamos database and a phylogenetic tree was created of in total 8,320 unique sequences. Transmission networks were defined as clusters of sequences with a bootstrap value ≥90%, within the 5th percentile threshold of the whole-tree patristic distance distribution including at least 10 patients in the ATHENA cohort.

Results: Amongst the 5,852 patients, 4,288 (73%) were MSM registered in the Netherlands. We identified 106 different transmission networks which included 3,061 (52%) ATHENA sequences. 50% (2,128) of 4,288 HIV cases amongst MSM in the Netherlands and 380 of the ‘Los Alamos’ sequences were included in 91 MSM majority networks (≥50%). Strikingly, 64 (70%) of these 91 MSM transmission networks were already circulating before 1996, the year that cART became widely available. Of the total 3,507 sequences among MSM with diagnoses after 1996, 41% (1,436) were found in these 64 networks, and 89% (57) of these networks include patients with proof of infection after 1996. Only in three of the 64 networks no new cases were diagnosed after 2006. The people pertaining these three networks had a higher median age at the study end date; 51 years (IQR: 45-52) in the persisting networks. Further, 68 MSM were in 10 of non-MSM dominated networks, and 1,324 (31%) were in 550 smaller clusters. 768 (18%) sequences amongst MSM in the Netherlands could not be identified as belonging to a network (singletons). Of MSM in a network, 4% have probably been infected abroad (according to their own report), versus 10% in the smaller clusters and 19% of singletons. If we regard every cluster, network, or singleton as a new HIV introduction, this totals to 1,419 HIV-1 subtype B introductions amongst MSM. Roughly indicating that 33% of infections amongst MSM were imported, and that 6% of introductions amongst MSM in the Netherlands gave rise to a local network.

Conclusions: The majority of the identified MSM-dominated transmission networks were already present before the introduction of cART and are still ongoing. Our analyses suggest that the resurgent epidemic is sustained by well-established networks, not brought to an end by the widespread use of cART.

206 Using HIV Networks To Inform Real Time Prevention Interventions

Susan J. Little1, Sergei L. K. Pond1, Christy M. Anderson1, Jason A. Young1, Joel O. Wertheim1, Sanjay R. Mehta2, Susanne May2, Davey M. Smith1
1 Medicine, University of California San Diego, San Diego, CA, United States, 2Biostatistics, University of Washington School of Public Health, Seattle, WA, United States

Background: Understanding the dynamics of HIV transmission may provide opportunities for public health interventions.

Methodology: We inferred a partial local transmission network among 478 recently HIV infected persons and 170 of their HIV infected sexual and social contacts in San Diego, California (n=648) using HIV pol sequences collected from 1996 to 2011. We linked two individuals (nodes) in the network whenever their pol sequences were less than 1.5% distant (Tamura Nei 1993 distance). Whenever possible, we assigned a direction to the network edge, based on the duration of infection for each partner. Using only baseline data after 2004, when network sampling was sufficiently dense (n=157), we defined a transmission network score (TNS) to estimate the risk of HIV transmission from a newly diagnosed individual to a new partner and potential impact of prevention interventions. TNS is a function of the total degree of the node at baseline (set to 0 if no connections are inferred), conditioned on the network inferred at the time of each subject’s baseline sequence.
Results: HIV-1 pol sequences from 339 of 648 individuals (52.3%) were linked to sequences from at least one other participant (i.e., clustered). The top quintile of the TNS distribution was designated as 'high' (TNS > 0.75, n=33) and all others as 'low' (n=124). Future transmission risk was characterized by identification of a new outbound connection within 1 year of enrollment. High TNS was significantly correlated with baseline risk behaviors (number of unique sexual partners and insertive unprotected anal intercourse (p=0.014 and 0.0455, respectively)). Baseline viral load (VL) and high TNS were not significantly correlated in univariate analysis (p = 0.27), but in a multivariable analysis, both VL and high TNS at baseline were independently correlated with predicted risk of HIV transmission within the first year after presentation (p=0.0164 and p=0.0018, respectively). Retrospective analysis of antiretroviral therapy (ART) use, and simulations of ART targeted to individuals with the highest TNS, suggested significantly reduced network level HIV transmission (p<0.05).

Conclusions: Sequence data from an HIV screening program focused on recently infected persons and their social and sexual contacts enabled the characterization of a highly connected transmission network. When TNS was incorporated into a multivariate model with VL, the prediction of transmission risk significantly improved, suggesting that VL and TNS are informed by independent transmission risk factors. The network-based TNS was significantly correlated with transmission risk behaviors and outcomes, and can be used identify and target effective prevention interventions, like ART, to those at a greater risk for transmitting HIV.

207 Transmission Networks of HIV-1 Subtype B, CRF01_AE and CRF51_01B Among MSM in Singapore
Kim Tien Ng1, Kah Ying Ng1, Wei Xin Khong1, Oliver Laeyendecker2*, Thomas C Quinn2*, Adeeba Kamarulzaman1, Don Tek Ng1, Kok Keng Tee1
1Centre of Excellence for Research in AIDS (CERiA), Department of Medicine, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia, 2Institute of Infectious Disease and Epidemiology, Communicable Disease Centre, Tan Tock Seng Hospital, Novena, Singapore.

Background: HIV-1 subtype B and CRF01_AE are the dominating subtypes among men who have sex with men (MSM) in Singapore. However, the evolutionary history, population dynamics and pattern of transmission networks of these genotypes remain unexplored. Here, we elucidated the phylodynamic profiles of HIV-1 subtype B, CRF01_AE and the recently characterized CRF51_01B strains circulating among the MSM population in Singapore.

Methodology: A total of 105 (49.5%) consenting treatment-naïve MSM were recruited between February 2008 and August 2009. HIV-1 RNA was extracted from plasma specimen, reverse-transcribed, followed by amplification of the protease gene (HXB2: 2239 - 2629), gr120 (HXB2: 6942 - 7577) and gp41 (HXB2: 7803 - 8276) of the env gene. The nucleotide sequences were codon aligned, followed by phylodynamic profiling using neighbour-joining reconstruction, maximum likelihood inference and Bayesian coalescence approach.

Results: Five monophyletic transmission networks (two each within subtype B and CRF01_AE and one within CRF51_01B lineages) of different sizes (involving 3 - 23 MSM subjects, supported by posterior probability measure of 1.0) were observed. Bayesian coalescent analysis estimated that the emergence of multiple sub-epidemic networks occurred between 1995 and 2005, driven largely by subtype B and followed by CRF01_AE. Exponential increase in effective population size for both subtype B and CRF01_AE occurred between 2002 to 2007 and 2005 to 2007, respectively. Genealogical estimates suggested that the novel CRF51_01B lineages were generated through series of recombination events involving CRF01_AE and multiple subtype B ancestors. The estimation of the divergence times for each node revealed that the median interval between transmission events within these networks were short, namely 0.9 years (0.1 - 4.7) in subtype B, 0.75 years (0.1 - 1.7) in CRF01_AE and 0.65 years (0.1 - 2.2) in CRF51_01B.

Conclusions: Our study provides the first insight into the phylodynamic profiles and evolutionary history of HIV-1 subtype B, CRF01_AE and CRF51_01B, suggesting the HIV-1 strains circulating among MSM in Singapore were introduced through multiple sub-epidemic networks. This study also unravels the importance of understanding transmission behaviours as well as evolutionary history of HIV-1 in assessing the risk of outbreak or epidemic expansion.

208 HIV-1 Phylodynamics and Phylogeography Among High-Risk and General Populations in Uganda
Gonzalo Yebra1, Manon Raggonet-Cronin1, Deogratius Ssemwangwa2, Chris M. Parry2, Pontiano Kaleebu2, Andrew J. Leigh Brown1
1Institute of Evolutionary Biology, University of Edinburgh, Edinburgh, United Kingdom, 2Research Unit on AIDS, MRC/Uganda Virus Research Institute, Entebbe, Uganda

Background: Uganda has historically had the highest HIV prevalence in East Africa. From the 1990s, this prevalence has declined sharply, but it has remained high within high-risk groups. Here, we reconstruct the history and spread of HIV subtypes A1 and D in Uganda, and explore the transmission dynamics of some high-risk populations.

Methodology: We analysed 162 HIV pol sequences from 3 Ugandan populations sampled in 2005-2010: female sex workers based in Kampala (n=42); Lake Victoria fisher-folk communities (n=46); and patients from a rural clinic in Masaka, south-west Uganda (n=74). We added GenBank sequences of subtype A1 (n=177) and D (n=235) from Uganda for which sampling city (mainly Kampala, Entebbe and Rakai) and date (1992-2005) were available. We used SCUEAL to identify recombinants. Clusters were defined by high statistical support (>90%) and low genetic distance (<4.5%). We applied Bayesian MCMC inference to these datasets using BEAST and conducted a phylogeographic analysis by using the discrete traits analysis implemented in BEAST.

Results: Of 162 pol sequences from high risk populations, 83 (51.2%) were subtype A1-like, 71 (43.8%) D-like and 8 (4.9%) were subtypes C and G. Subtype A1 was dominant (58%) in the cities (Kampala, Entebbe) but subtype D was more frequent (74%) in the rural areas (Rakai, Masaka). Sixty-seven recombinants were discarded. Most (84%) of the 71 observed clusters were pairs, and few (10.5%) included individuals from different populations. Half of the sequences from rural regions were included in clusters, while sequences from other populations or locations were more interspersed in the trees. The dates of the most recent common ancestors were 1945.4 (1923.5 - 1962.6) for pure subtype A1 and 1965.6 (1958.5 - 1972.3) for pure subtype D, consistent with results published for other HIV gene segments. The Bayesian Skygrid showed a matching temporal trend in the population size for both
subtypes, with an exponential growth in the 1970s and 1980s and a decrease since the early 1990s. For both subtypes, the origin of the epidemic was located to rural southwest Uganda (Masaka, Rakai) with further radiations from Kampala to other locations as Entebbe and Lake Victoria.

Conclusions: The subtype A1 epidemic in the region appeared very old (originating in the 1940s), with subtype D entering in the 1960s. The phylogenies showed a star-like topology attributed to the great root-to-tip distances due to the old age of these clades. Sequences from rural areas were more likely to cluster, while sequences from fishermen and sex workers were interspersed in the trees. Finally, our results pointed to the south-western rural areas as the probable origin of the Ugandan epidemic, in contrast to other hypotheses that inferred the origin of HIV in large cities.

209 Sustained Spread of HIV-1 Drug Resistance in Treatment-Naive Patients in the United Kingdom

Jean L. Msbisa1, Esther Fearnhill1, David T. Dunn2, Deenan Pillay3, David Asboe1, Patricia Anne Cane1, on behalf of the UK HIV Drug Resistance Database

1Virus Reference Department, Public Health England, London, United Kingdom, 2Medical Research Council Clinical Trials Unit, University College London, London, United Kingdom, 3Research Department of Infection, University College London, London, United Kingdom, 4Directorate of HIV Medicine and Sexual Health, Chelsea and Westminster Hospital, London, United Kingdom

Background: Transmitted drug resistance (TDR) in the UK peaked at about 15% of those tested between diagnosis and initiation of ART in 2002 but has since declined to 8–9%. Originally, the proportion of specific TDR mutations mostly mirrored those observed in treated patients when ~80% of resistance tests undertaken on treated patients showed drug resistance mutations (DRMs). In recent years 60–70% of resistance tests from treated patients show no resistance mutations and there is a marked discordance between the mutation patterns observed in failing patients and those seen in new diagnoses. This suggests onward transmission of TDR from untreated and possibly undiagnosed patients.

Methodology: We extracted all subtype B HIV-1 pol gene sequences from treatment-naive patients within the UK HIV drug resistance database sampled between 1997-2011 with any of DRMs: L90M - protease; K103N, T215Y and T215 revertants - reverse transcriptase (n=1140). These DRMs were chosen as the most common associated with PI, NNRTI and NRTI TDR in the UK database. Sequence alignments with DRMs removed were used to identify transmission clusters (n=2) by maximum-likelihood phylogeny using a genetic distance cut-off of ±1.5% and high bootstrap support. The time of origin of the large clusters containing ≥8 sequences was estimated by Bayesian Markov chain Monte Carlo approach and a birth-death model was employed to estimate the basic reproductive numbers (R0) of individual clusters (subepidemics).

Results: The most common TDR DRM seen in 1140 patients was T215rev which was present in 47% (n=540) of the sequences, followed by K103N (31%; n=359) and L90M (10%; n=109). The remaining sequences contained T215Y or combinations of L90M, K103N and T215rev. Fifty-five percent (n=624) of the sequences formed highly supported transmission clusters (n=193) containing between 2 and 15 sequences with 115 clusters containing 3 or more sequences. The time of origin of the 10 large clusters containing 8 or more sequences was estimated to be between 2000 [1999-2002; 95% highest posterior density (HPD)] and 2006 [2005-2007; 95% HPD]. The oldest subepidemic was formed of 10 sequences containing the K103N mutation and was found to have persisted for nearly 9 years. All 10 clusters were shown to have R0s ranging between 1.3 [0.4-2.5; 95% HPD] and 2.8[0.6-6.5; 95% HPD] meaning that on average each person in the clusters is responsible for infecting more than one person over the sampling period. This suggests the likelihood of sustained spread of the TDR lineages within treatment-naive patients.

Conclusions: A high proportion of observed TDR is derived by onward transmission in treatment-naive patients. This could be decreased by enhanced testing to reduce late diagnosis.
Conclusions: These results confirm surveillance data demonstrating high rates of HIV transmission among young Black males in Chicago. Applied prospectively, phylogenetic clustering analysis could guide targeted contact tracing activities, helping to break the cycle of transmission within active clusters. Exploration of the social networks of clustered patients may reveal high yield areas for venue based prevention and guide test and treat initiatives in Chicago.

Investigation of HIV Transmission Dynamics Reveals “Active” Clusters of Men Who Have Sex With Men
Philip A. Chan1, Austin Huang2, Allison DeLong3, Joseph Hogan3, Marissa Reitsma1, Marco Salemi4, Rami Kantor1
1Medicine, Brown University, Providence, RI, United States, 2Computer Science, Brown University, Providence, RI, United States, 3Center for Statistical Sciences, Brown University, Providence, RI, United States, 4Pathology, University of Florida, Gainesville, FL, United States

Background: New HIV infections in the US continue to increase, driven in part by local transmission networks among at-risk populations. Phylogenetic characterization of clusters and examination of their dynamics can provide information on HIV transmission and identify actively growing clusters which may be targeted for intervention.

Methodology: To investigate transmission cluster dynamics, HIV pol sequences from 2004-2011 at a large outpatient clinic were analyzed. Phylogenetic trees were constructed in MEGA and clusters were identified in PhyloPart. We examined (1) Associations between risk behavior and cluster size using latent class analyses and ordinal logistic regression; (2) Homogeneity of risk factors within clusters using general estimating equations (GEE2); and (3) Active transmission activity in clusters (i.e. active clusters) was assessed based on the probability of one or more new diagnoses in the year after the data collection period.

Results: Of 41,294 sequences, 12,910 (31%) linked to ≥1 other sequence (range: 1-83), and 3,982 (10%) linked to ≥4 sequences. Males represented 78% of the sample and 93% of persons with ≥4 links. Persons aged 20-29 years represented 34% of the sample and 51% of persons with ≥4 links. White persons represented 26% of the sample and 34% of persons with ≥4 links. Although black persons represented almost half (47%) of the sample, they represented a smaller percentage of persons with ≥4 links (41%). Men who have sex with men (MSM) represented 61% of the sample and 86% of persons with ≥4 links (Figure). In multivariable analysis, age, race/ethnicity, and transmission category were independently associated with having ≥4 links (p<0.0001), although sex was not.

Conclusions: MSM and young persons are overrepresented among persons with many potential links, suggesting that they are disproportionately involved in networks associated with HIV transmission; this finding corroborates other analyses demonstrating high HIV incidence among these groups. Efforts to interrupt HIV transmission and reduce incidence must reach these groups. Implementation of intensive and other effective interventions should prioritize MSM and young persons.
Results: At least one HIV-1 subtype B pol sequence was available for 1,166 patients diagnosed from 1980-2011. Thirty-one percent (358/1,166) of sequences formed 114 distinct clusters (cluster size range 2-15). Men who have sex with men (MSM) were more likely to be in clusters than not (52% vs. 35%, p<0.01) whereas injection drug users were less likely to be in clusters (11% vs. 25%, p<0.01). One latent class was comprised primarily of MSM diagnosed after 2003. Members of this class were more likely to be in larger clusters compared to the other 3 classes (odds ratio [OR] range 1.69-11.63, p<0.01) and were more heterogeneous in terms of risk factor for HIV infection. Compared to a cluster size of 2, the likelihood of a cluster being comprised only of MSM was reduced for cluster sizes of 3 (OR 0.08 [0.01-20.9 95% CI], p=0.7), 4 (OR 0.08 [0.1-1.4 95% CI], p=0.08) and >6 (OR 0.12 [0.03-3.33 95% CI], p=0.21). In the logistic growth modeling, cluster growth rates were estimated for 24/114 clusters with >3 individuals. Seventeen percent (4/24) of clusters containing 24% (38/161) of individuals were identified as active with >15% probability of harboring undiagnosed infections. Of the 38 members of the active clusters, 100% were male, 90% MSM and 45% were diagnosed with primary HIV infection.

Conclusions: In our community, the HIV epidemic is driven by local transmission networks among MSM which should be further explored. Phylogenetic examination of cluster dynamics can reveal active clusters that have the potential of harboring undiagnosed infections and represent targets for intervention.

HIV Transmission in the United States: The Roles of Risk Group, Race/Ethnicity, and Geography
Alexandra M. Oster1, Joel O. Wertheim1, Angela L. Hernandez1, Marie C. B. Ocfemia1, Neeraja Saduvala1, David Kim1, H. I. Hall1
1Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, GA, United States, 2ICF International and University of California San Diego, San Diego, CA, United States, 3ICF International, Atlanta, GA, United States

Background: The study of HIV transmission networks provides insight into the spread of HIV, and thus into opportunities for intervention. By identifying genetically similar HIV variants in large datasets, we can construct such transmission networks. Two persons infected with highly similar HIV variants are likely to have a direct or indirect epidemiologic connection and represent potential transmission partners. Transmission dynamics between people who are similar or different with respect to race/ethnicity, risk characteristics, and geography are unclear. To identify demographic and risk characteristics of potential transmission partners, we constructed a U.S. HIV transmission network.

Methodology: We analyzed 41,294 HIV-1 pol sequences collected through the U.S. National HIV Surveillance System (NHSS) during 2001-2012. We aligned sequences (one/person aged ≥13 years) to a reference sequence (HXB2) and performed pairwise comparisons among all sequences. Possible linkages were defined by Tamura-Nei 93 genetic distance ≤1.5%. We constructed a transmission network and analyzed data on risk group (MSM, IDU, MSM/IDU, heterosexual), race/ethnicity, and state of residency at diagnosis for pairs of potential transmission partners.

Results: The network contained 12,910 nodes (31% of all sequences) and 29,493 connections. MSM comprised 61% of persons with sequences but 76% of the network. In the vast majority of transmission pairs containing at least one MSM, the second person was also MSM (MSM: 82%, MSM/IDU: 7%) (Table). Heterosexual women were more commonly connected to MSM (44%) than to heterosexual males (18%) or IDUs (13%). MSM/IDU were far more commonly connected to MSM (88%) than to IDUs (2%). Transmission pairs containing blacks/African Americans were more racially homogeneous (63%) than pairs containing whites (47%) or Hispanics (27%). Of pairs, 82% consisted of two persons living in the same state at diagnosis; this percentage was higher for pairs with female IDUs (90%) and heterosexual women (91%).

MSM: men who have sex with men; IDU: injection drug user; NHOPI: Native Hawaiian or Other Pacific Islander

*Other race includes American Indian/Alaska Native, other race, multiple races, or unknown race
Conclusions: This analysis is the first use of NHSS data to infer an HIV transmission network. Geographic and racial/ethnic mixing in HIV transmission were present, although the extent varied by population. The majority of potential transmission partners connected to MSM were also MSM, but other risk groups were also commonly connected to MSM. Interventions that reduce transmissions by MSM are likely to reduce HIV acquisition among other risk groups as well.

214 Risk Factor Predicts Geographic Spread Within New York City HIV-1 Transmission Network and Beyond
Joel O. Wertheim1, Sanjay R. Mehta2, Sergi L. Kosakovsky Pond3, Davey M. Smith4, Lisa A. Forgione2, Lucia L. Torian2
1University of California, San Diego, San Diego, CA, United States, 2New York City Department of Health and Mental Hygiene, New York, NY, United States
Background: HIV transmission networks inferred from sequence data can be used to identify risk groups for intervention. Transmission clusters spread over larger geographic areas may require different methods of intervention than localized clusters. We investigated how individual transmission risk factor predicted the geographic spread of HIV within and outside NYC.

Methodology: We analyzed 39,135 individuals’ earliest HIV pol sequence reported to NYC through routine laboratory surveillance during 2005-2012. All sequences were aligned to the reference genotype HXB2. Potential transmission partners were defined as two individuals whose sequences had a pairwise genetic distance ≤2%; groups of linked partners formed transmission clusters. We applied multivariate logistic and ordinal logistic regression to identify characteristics associated with clustering and geographic spread. NYC geographical information was derived from zip code of residence at diagnosis as grouped into standard multi-zip NYC neighborhoods. We also included 86,216 non-US sequences from the Los Alamos National Laboratory (LANL) HIV sequence database to investigate global transmission links.

Results: The network contained 8801 nodes (22.5% of all individuals) and 19,637 edges (connections between potential transmission partners). Propensity for clustering within the NYC network was not uniform: men who have sex with men (MSM) were more likely to cluster than heterosexuals (OR = 2.4; p < 0.001), and injecting drug users (IDU) were less likely to cluster than heterosexuals (OR = 0.52; p < 0.001). Both MSM and IDU had transmission partners spread over a greater median distance than heterosexuals (10.3 and 9.0 vs. 7.8 km; p < 0.01). Of all individuals clustered within the NYC network, 28.3% have a potential partner diagnosed within, but residing outside of, NYC. Among individuals connected in the NYC network, MSM were more likely to cluster with individuals residing outside of NYC than heterosexuals (36.6% vs. 8.2%; p < 0.001), but not with individuals from other countries in the LANL reference dataset. IDU were unexpectedly more likely than heterosexuals to have an international connection in LANL (18.5% vs. 6.2%; p < 0.001).

Conclusions: Risk factor plays an important role in predicting the geographic spread of HIV transmission clusters. MSM have the most geographically expansive clusters. However, IDU clusters are not as geographically constrained (locally or internationally) compared with heterosexual clusters. Interventions targeting specific risk groups should take the geographic spread of these clusters into account.

215 Large MSM Group and Local Heterosexual Transmission Are Major Concerns in the HIV Epidemic in Japan
Teiichiro Shin1o, Kenji Sadamasu2, Junko Hattori1, Mami Nagashima1, Yasumasa Iwata1, Yoshiyuki Yokomaku1, Wataru Sugiu1a, The Japanese Drug Resistance HIV-1 Surveillance Network
1Infectious Diseases Surveillance Center, National Institute of Infectious Diseases, Tokyo, Japan, 2Tokyo Metropolitan Institute of Public Health, Tokyo, Japan, 3Clinical Research Center, Nagoya Medical Center, Nagoya, Japan
Background: To clarify HIV transmission dynamics from a large collection of viral sequences, a useful tool is phylodynamic analysis. We used this tool to analyze HIV pol sequence data from our nationwide surveillance network to reveal the dynamics of HIV transmission in Japan.

Methodology: Nucleotide sequences of the protease-reverse transcriptase (RT) gene were obtained from 4393 newly diagnosed HIV patients in 2003-2011. These sequences were then aligned with subtype reference sequences retrieved from the HIV database, and subtypes belonging to each sequence segment were determined using similarity plot analysis against subtype references. Domestic transmission clusters (infection networks) were identified by combined monophyly evaluation using three different phylogenetic methods: neighbor-joining method with interior branch test, maximum likelihood method, and Bayesian Markov chain Monte Carlo (MCMC) method. Chronological phylogeny, median time of the most recent common ancestor (MRCA), and basic reproductive number (R0) were also inferred by Bayesian MCMC coalescent analysis using BEAST1.7.4.

Results: The predominant subtypes in Japan (with number of patients and prevalence) were subtype B (n=3899: 88.8%) and CRF01_AE (n=344: 7.8%). Other minor subtypes were found: C (n=46), CRF02_AG (n=36), G (n=15), F (n=9), CRF06_cpx (n=3), CRF07_BC (n=2), and CRF12_BF (n=2), and CRF33_01B (n=2). Subtypes D, CRF08_BC and CRF28 or 29_BF were detected in one patient. Another 32 patients had unknown forms of intra-subtype recombinants. Phylogenetic analysis yielded four major findings. 1) Although tMRCA of a few infection networks of subtype B dated to the 1980s, many had spread between men having sex with men (MSM) from the second half of the 1990s. 2) CRF01_AE was also transmitted into Japan through heterosexual and intravenous drug user routes in the 1990s. 3) In the 1990s, minor subtypes and recombinant viruses also colonized in some groups that mingled with foreigners. 4) In the 2000s, CRF01_AE was also transmitted to MSM communities and might have generated some domestically circulated recombinants between subtypes 01_AE and B. R0 of subtypes B, C, F and CRF01_AE in Japan (3.3, 3.2, 2.1, and 3.7, respectively) did not differ significantly, but the R0s of subtypes G and CRF02_AG (7.7 and 6.9) were significantly higher than those of other subtypes.

Conclusions: These results suggest that a large MCM community with intra-subtype recombinants and a local population network with high infectivity females are major concerns in Japan.
Full-Length HIV-1 Haplotype Reconstruction From Heterogeneous Virus Populations

Armin Töpfer1,2, Francesca Di Girolomoni3,4, Melanie Rey5, Sandhya Prabhakaran5, Yannik Duport3, Christine Leemann3,4, Huldrych F. Günthard3, Volker Roth5, Niko Beerenwinkel1,2, Karin J. Metzner3

1D-BSSE, ETH Zurich, Basel, Switzerland, 2SIB Swiss Institute of Bioinformatics, Basel, Switzerland, 3University of Zurich, Zurich, Switzerland, 4Life Science Zurich Graduate School, Zurich, Switzerland, 5University of Basel, Basel, Switzerland

Background: Next-generation sequencing (NGS) can provide in-depth resolution of heterogeneous intra-patient viral populations, composed of one or more genetically distinct haplotypes. However, such analyses are complicated by small read length, up to two orders of magnitude shorter than the genome size, and by the error rate of amplification and sequencing. Identification of co-occurring resistance mutations, composition, and ongoing evolution of intra-patient viral populations on the basis of full-length genomes are of great interest, but remain unsolved. New approaches and tools are needed to reconstruct individual full-length haplotypes and to estimate their frequency in the population.

Methodology: We combined five molecular HIV-1 strains to create a heterogeneous mixture of viral haplotypes. RNA was isolated and whole genomes amplified with three different protocols for the NGS technologies 454/Roche, Illumina, and PacBio. For each data set, we performed full-length haplotype reconstruction over the complete coding region of 8,627 bp, using the software packages QuasiRecomb and PredictHaplo. To determine the ground truth sequences and frequencies, we sequenced the HIV-1 strains individually and performed single-genome amplification (SGA) on the protease gene.

Results: Applying the NGS platforms 454/Roche, Illumina, and PacBio, we amplified and sequenced 35, 5, and 11 amplicons, with average read length (mean±sd) 410±41 bp, 237±26 bp, and 1499±77 bp, and average coverage (range) 7,712 (2,237-22,661), 23,010 (5,084-47,232), and 1,741 (450-3,147) reads per nucleotide, respectively. We reconstructed all five full-length haplotypes error-free from p17 in gag to nef. Estimated frequencies were almost identical between the independent reconstruction methods QuasiRecomb and PredictHaplo, in agreement with SGA, and very stable for 100 bootstrap samples with a mean variance of 0.4% across strains and technologies. Full-length frequency estimates were more reliable than gene-wise estimates.

Conclusions: Full-length haplotype reconstruction from a heterogeneous HIV-1 sample is technically feasible. It depends critically on amplicon layout and successful amplification, sufficient read length, and homogeneous coverage. Our protocols and methods to decompose a heterogeneous population into individual full-length haplotypes can be used to identify quasispecies structures and study evolution of viral populations.

Limited HIV-1 Superinfection in Seroconvertors From the CAPRISA 004 Microbicide Trial

Andrew Redd1, Caroline Mullis2, Daniel Sheward3, Carolyn Williamson3, Lise Werner1, Nigel Garrett2, Stephen Porcella2, Quarraisha Abdool Karim4, Thomas Quinn1, Salim Abdool Karim1

1NIAID, Baltimore, MD, United States, 2The Johns Hopkins, Baltimore, MD, United States, 3University of Cape Town, Cape Town, South Africa, 4CAPRISA, Durban, South Africa, 5NAID, Hamilton, MT, United States

Background: HIV superinfection (SI) occurs when an infected individual acquires a new viral strain that is phylogenetically distinct from all previous viral strains. This study examined if HIV SI as identified by next-generation sequencing (NGS) occurred at a rate similar to the rate of primary incidence in the CAPRISA 004 trial.

Methodology: Viral sequences were successfully generated for 76 of the 96 women screened who acquired HIV during the trial and had available plasma samples within the first 3 months of infection and a second sample prior to initiation of anti-retroviral therapy (median time from infection=111 weeks). Viral RNA was extracted from plasma, reverse-transcribed, and amplified for regions of the viral p24 and gp41 genes, and was sequenced using the 454 platform. All similar sequences were combined into a single consensus sequence, which were used for all subsequent phylogenetic analyses.
HIV superinfection was defined when an individual’s second sample demonstrated two or more distinct consensus sequences forming a phylogenetically distinct cluster unlinked from the individual’s consensus sequences in the initial sample. Recent sexual partner status for the 96 women screened was examined as possible risk factor for SI.

Results: Two women were found to have been superinfected from all women screened (2.6%). There was one case of SI identified in each arm, and in each case the women experienced a spike in their viral loads of at least 0.5 log10 between visits when the SI was first detected. The rate of SI for the serocounters screened was calculated to be 1.5/100 pys [95% confidence intervals (CI) =0.2-5.4], which was significantly lower than the observed primary infection rate of 7.3/100 pys as observed for the total trial population [RR=0.20, 95% CI=0.02-0.75; p=0.003].

80% of women screened reported having sex in the last thirty days with a stable partner pre-infection, but a significantly higher percentage of these women (99%) reported having sex with a stable partner at the timepoint near the initial SI screening sample (p = <0.001).

Conclusions: The observed frequency of SI appears lower than primary HIV incidence in this population. This was unexpected and in contrast to a previous finding by our group in Uganda where the rate of SI was similar to the rate of primary infection in a general population cohort. A study of high-risk women in Kenya also found a significantly lower rate of SI compared to primary incidence, which agrees with these findings. Interestingly, the percent of women who reported sex with a stable partner increased after seroconversion. More research in a variety of populations is needed to fully clarify the relationship between HIV-SI risk and primary incidence, which could have important implications for HIV vaccine efforts.

218 Analysis of PCR Bias Using Primer IDs and Illumina Sequencing of HIV RNA Populations
Valerie F. Boltz1, Wei Shao1, Mary F. Kearney1, John W. Mellors1, Frank Maldarelli2, John M. Coffin2
1Drug Resistance Program, National Cancer Institute, Frederick, MD, United States, 2Advanced Biomedical Computing Center, Leidos Biomedical Research, Inc, Frederick, MD, United States, 3Division of Infectious Disease, University of Pittsburgh, Pittsburgh, PA, United States, 4Department of Molecular Biology and Microbiology, Tufts University, Boston, MA, United States

Background: The study of HIV population genetics and pathogenesis is greatly improved by deep sequencing of HIV-1 genomic DNA and RNA. To achieve sequences that accurately represent the virus population, primer IDs containing 10 random bases have been used to label each molecule with a unique sequence during cDNA synthesis. However the use of primer IDs reveals an apparent PCR bias in which a large fraction of the resulting sequences obtained are represented only once in the dataset. This effect has hampered progress. Here we describe a source of this bias.

Methodology: We hypothesized that carryover into the PCR reaction of unused primer IDs from the cDNA synthesis step could give the appearance of inefficient amplification of templates. To test this idea, cDNA was synthesized from wild-type HIV-1 BH10 pol transcripts using one primer ID to tag all molecules in the reaction identically. Separately, and using a different known primer ID sequence, cDNA was synthesized from transcripts containing drug resistance mutations. The two dissimilarly tagged cDNA reactions were purified, mixed and amplified together with illumina primers. Products were sequenced using paired-end Illumina MiSeq technology. In parallel, plasma HIV RNA from a chronically HIV-infected patient was labeled with primer IDs containing 10 random bases, amplified and sequenced the same way. The sequencing data were used to build consensus sequences from reads that shared the identical primer IDs and analyzed for PCR bias.

Results: We observed substantial carryover of the primers containing IDs used for cDNA synthesis into the PCR reactions resulting in frequent mislabeling of sequences giving the appearance of PCR bias. Of 234,680 sequences obtained from the samples that were tagged individually, 23.8% of the molecules sequenced were labeled with the wrong primer ID; 18.5% of WT molecules were labeled with the mutant ID and 5.3% of the mutant molecules were of sequences giving the appearance of PCR bias. Of 234,680 sequences obtained from the samples that were tagged individually, 23.8% of the molecules sequenced were labeled with the wrong primer ID; 18.5% of WT molecules were labeled with the mutant ID and 5.3% of the mutant molecules were labeled with the WT ID. In addition, 25% of the sequences from the plasma HIV RNA sample were mislabeled (assuming each HIV RNA molecule would be unique after long-term chronic infection), as many identical sequences were tagged by more than one primer ID. Interestingly, in the same patient sample, two different HIV RNA molecules were never labeled with the same primer ID.

Conclusions: Our results show that up to 25% of sequences derived from HIV RNA may be artifacts from carryover of primer containing IDs into the PCR reaction. This problem limits the accuracy of the current primer ID approach for studying HIV populations. New methods can now be developed to eliminate the carryover of primer IDs while maintaining the unique tagging of individual templates and subsequent sequences to achieve results that accurately represent the virus population being studied.

219 HIV Surveillance and Parallel Virome Analysis Using Unbiased Next-Generation Sequencing
Ka-Cheung Luk1, Michael Berg2, Samia Nacache1, Scott Federman2, Charlotte Nganopo1, Dora Mbanya1, Lazare Kaptue3, Charles Y. Chiu1, John Hackett1
1Abbott Diagnostics, Abbott Park, IL, United States, 2University of California, San Francisco, San Francisco, CA, United States, 3Universite de Yaounde, Yaounde, Cameroon, *Universite des Montagnes, Bangangte, Cameroon

Background: Next-generation sequencing (NGS) has the potential to revolutionize strategies for HIV surveillance, genome characterization, and minor variant analysis. Moreover, application of this technology in an unbiased manner offers the promise of simultaneous detection and characterization of viral coinfections. In this study, we examined the utility of high-throughput sequence analysis for characterization of HIV and detection of known and novel viruses.

Methodology: Thirty-five plasma specimens from HIV-1-infected Cameroonian blood donors were selected for analysis based on partial genome characterization (gag p24, pol IN and env IDR) using traditional Sanger sequencing. NGS cDNA libraries prepared using nuclease pre-treatment followed by RNA extraction and random-primed reverse transcription were multiplexed (4-5 libraries/run) and run on a MiSeq instrument. Sequence data was analyzed using a customized bioinformatics pipeline for rapid pathogen identification, SURPI, to identify and bin all viral sequences. Phylogenetic analysis was performed with PHYLIP and HIV-1 recombinants were characterized using SimPlot.
Results: HIV-1 related sequences ranged from 0.002% to 4.11% of total sequences yielding >90% coverage for 83% of samples. Complete genomes were assembled for 26 strains including 7 CRF11_cpx and 2 CRF13_cpx, 1 CRF18_cpx, 2 CRF22_01A, and 1 CRF37_cpx, circulating recombinant forms with relatively limited data available as well as 8 unique recombinant forms. Average depth of genome coverage ranged from 121- to 8972-fold. Bioinformatics analysis revealed the presence of numerous other viruses. Notably, GBV-C (HPgV) co-infection was detected in 65% of samples. Eight samples yielded complete GBV-C genomes with read numbers ranging from 0.19% to 4.40%. These GBV-C genomes formed a unique cluster in genotype 1 with Ghanian sequences distinct from S. African reference strains. Additional detected viruses included hepatitis B virus, adeno-associated virus, hepatitis delta virus, human parvovirus B, human rhinovirus C, and viral sequences with distant homology (<70% aa identity) to small circular DNA viruses (circoviruses, cycloviruses, and geminiviruses).

Conclusions: These data demonstrate the utility of unbiased NGS for HIV-1 surveillance, rapid viral genome characterization, and for simultaneous screening of known and potentially novel viruses. Moreover, the extent of HIV-1 genome coverage substantially increases confidence in phylogenetic classification of strains. This technology coupled with powerful bioinformatics represents an unparalleled opportunity to characterize the virome and decipher interrelationships between HIV-1 and other viral infections.

220 Primer ID Deep Sequencing of HIV-1 env Region To Reveal Genetic Structure of Viral Population

Shuntai Zhou1, Maria Bednar1, Christa Sturdevant1,2, Serena Spudich1, Richard Price1, Ronald Swanstrom1,5
1 Lineberger Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 2 Department of Microbiology and Immunology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 3 Department of Neurology, Yale University, New Haven, CT, United States, 4 Department of Neurology, University of California at San Francisco, San Francisco, CA, United States, 5 UNC Center For AIDS Research, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 6 Department of Biochemistry and Biophysics, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Background: HIV env gene consists of several highly variable regions and is a major determinant of pathogenesis, disease progression, and entry phenotype. However, deep sequencing env gene by next generation sequencing (NGS) is challenging. By using a stretch of randomized bases (Primer ID) at cDNA synthesis step prior to NGS to reduce PCR and sequencing errors and provide accurate frequencies of minority variants in the viral population, we developed an approach to deep sequence the V1-V3 region of the env gene to detect X4 variants and define the genetic structure of the viral population within individual subjects.

Methodology: Viral RNA was extracted from plasma samples obtained from 10 late-stage and 6 early-stage HIV-1 infected patients. Primers with Primer ID were used for cDNA synthesis. We used MiSeq 250 bp pair-end sequencing to sequence an amplicon covering most of V1/V2 region, all of the V3 region, and part of C2 region. In-house bioinformatics pipelines were used to create consensus sequences of the same Primer IDs. Entry tropism was predicted by V3 sequences using the Gene2Pheno [coreceptor] (False Positive Rate, FPR) algorithm. A control plasmid was amplified, sequenced, and analyzed along with clinical samples. We also used single genome amplification (SGA) to obtain env sequences from the same samples, and in vitro entry-phenotype was examined using cloned env gene.

Results: Sequencing data from the control plasmid showed that the residual error rate of this approach was 1 error in 4,000 bases. The number of consensus sequences was linearly correlated with template numbers (R2 = 0.999). We obtained an average of 1,084 and 1,532 consensus sequences for late-stage and early-stage subjects, respectively. X4 viruses were detected in 8 out of 10 late-stage samples. Phylogenetic analysis of C2/V3 sequences revealed that the most stringently called X4 viruses (Geno2Pheno, FPR <= 2%) formed distinct lineages in all the samples containing X4 viruses. Entry phenotype analysis suggested that all lineages gave phenotypic results consistent with FPR <= 2% being true X4 lineages. Analysis of both V1/V2 and C2/V3 regions showed that there was very little recombination between the X4 and R5 lineages, while some of the multiple R5 lineages or X4 lineages themselves had extensive recombination between these regions.

Conclusions: Primer ID combined with NGS provides a novel approach to deep sequencing highly variable region of HIV-1 with low error rate and accurate allelic frequency. Clustering of sequences with low FPR of X4 is an additional type of information to predict X4 calls based on sequence analysis. Restricted recombination of X4 and R5 viruses suggest these variants are genetically isolated either producing nonviable recombinants or replicating in distinct cell types.

221 Using RNAsSeq To Characterize Viral Genetic Diversity in a Cohort of HIV-2 Monoinfected Individuals

Katherine L. James1, Louis-Marie Yindom1, Thushan De Silva1, Shokouh Makvandi-Nejad1, Stephen Taylor1, Hilton Whittle1, Tim Vincent1, Gilean McVean2, Sarah Rowland-Jones1
1 NDM, University of Oxford, Oxford, United Kingdom, 2 University of Sheffield, Sheffield, United Kingdom, 3 Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom, 4 London School of Hygiene and Tropical Medicine, London, United Kingdom, 5 Medical Council Research Unit, Fajara, Gambia, 6 Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom

Background: HIV-2 disease progression appears to be bimodal. Approximately 20% of patients progress to AIDS in a manner similar to HIV-1 infection, whilst a significant proportion (37% in the Caió cohort) maintain high CD4+ T cell counts and plasma viral loads below detection in the absence of ART, equivalent to a “functional cure”. Previous work on HIV-2 plasma genetic diversity has been limited and mostly focused on single genes from patient derived clones. A bias-free method of whole genome sequencing may help to elucidate whether there is a correlation between HIV-2 viral diversity and disease progression, whilst a significant proportion of relatively limited data available as well as 8 unique recombinant forms. Average depth of genome coverage ranged from 121- to 8972-fold. Bioinformatics analysis revealed the presence of numerous other viruses. Notably, GBV-C (HPgV) co-infection was detected in 65% of samples. Eight samples yielded complete GBV-C genomes with read numbers ranging from 0.19% to 4.40%. These GBV-C genomes formed a unique cluster in genotype 1 with Ghanian sequences distinct from S. African reference strains. Additional detected viruses included hepatitis B virus, adeno-associated virus, hepatitis delta virus, human parvovirus B, human rhinovirus C, and viral sequences with distant homology (<70% aa identity) to small circular DNA viruses (circoviruses, cycloviruses, and geminiviruses).

Conclusions: These data demonstrate the utility of unbiased NGS for HIV-1 surveillance, rapid viral genome characterization, and for simultaneous screening of known and potentially novel viruses. Moreover, the extent of HIV-1 genome coverage substantially increases confidence in phylogenetic classification of strains. This technology coupled with powerful bioinformatics represents an unparalleled opportunity to characterize the virome and decipher interrelationships between HIV-1 and other viral infections.

Methodology: Viral RNA was extracted from plasma samples obtained from 10 late-stage and 6 early-stage HIV-1 infected patients. Primers with Primer ID were used for cDNA synthesis. We used MiSeq 250 bp pair-end sequencing to sequence an amplicon covering most of V1/V2 region, all of the V3 region, and part of C2 region. In-house bioinformatics pipelines were used to create consensus sequences of the same Primer IDs. Entry tropism was predicted by V3 sequences using the Gene2Pheno [coreceptor] (False Positive Rate, FPR) algorithm. A control plasmid was amplified, sequenced, and analyzed along with clinical samples. We also used single genome amplification (SGA) to obtain env sequences from the same samples, and in vitro entry-phenotype was examined using cloned env gene.

Results: Sequencing data from the control plasmid showed that the residual error rate of this approach was 1 error in 4,000 bases. The number of consensus sequences was linearly correlated with template numbers (R2 = 0.999). We obtained an average of 1,084 and 1,532 consensus sequences for late-stage and early-stage subjects, respectively. X4 viruses were detected in 8 out of 10 late-stage samples. Phylogenetic analysis of C2/V3 sequences revealed that the most stringently called X4 viruses (Geno2Pheno, FPR <= 2%) formed distinct lineages in all the samples containing X4 viruses. Entry phenotype analysis suggested that all lineages gave phenotypic results consistent with FPR <= 2% being true X4 lineages. Analysis of both V1/V2 and C2/V3 regions showed that there was very little recombination between the X4 and R5 lineages, while some of the multiple R5 lineages or X4 lineages themselves had extensive recombination between these regions.

Conclusions: Primer ID combined with NGS provides a novel approach to deep sequencing highly variable region of HIV-1 with low error rate and accurate allelic frequency. Clustering of sequences with low FPR of X4 is an additional type of information to predict X4 calls based on sequence analysis. Restricted recombination of X4 and R5 viruses suggest these variants are genetically isolated either producing nonviable recombinants or replicating in distinct cell types.
HIV-2 genome and the HIV-2 specific accessory gene Vpx in overlapping amplicons. Amplicons were sequenced using Sanger sequencing technology to verify HiSeq data.

Results: Full Genome sequence data will be presented from 3 HIV-2 clinical samples and 2 laboratory HIV-2 strains. We have, for the first time, used RNASeq methods to generate whole HIV-2 genome sequences directly from patient plasma with an average of 10x coverage. Our results show RNASeq can be used to generate data from small volumes (500µL) of plasma or cell culture supernatant, a crucial aspect when working with limited samples from remote cohorts. Alongside complete HIV-2 genomes, we also present the first HIV-2 Vpx sequences derived directly from patient plasma rather than patient-derived clones.

Conclusions: We have demonstrated that RNASeq is a feasible and valuable tool for generating HIV-2 whole genome sequences directly from patient plasma without the need for sequence-specific amplification or clonal expansion, reducing biases introduced during sample-preparation. As these samples were collected from a well-characterized community cohort with a long follow up time, we will outline methods to combine patient clinical data and HLA-type with RNASeq data to look for associations with disease progression. Whole genome HIV-2 sequences provide a powerful tool to elucidate the mechanisms of viral suppression in HIV-2 controllers, a natural model of attenuated HIV progression.

222 Next Generation Sequencing of Full-Length HIV-1 env During Primary Infection
Melissa E. Laird1, N. Lance Heptler1, Colleen Ludka1, Michael Brown1, Stephen Espitia1, Yan Guo2, Douglas D. Richman1, 4, Sergei Kosakovsky Pond1, Ellen E. Paxinos2, Davey M. Smith1, 4
1University of California, San Diego, La Jolla, CA, United States, 2Applications and Collaborations, Pacific Biosciences, Menlo Park, CA, United States, 3Bioinformatics, Pacific Biosciences, Menlo Park, CA, United States, 4Veterans Affairs San Diego Healthcare System, San Diego, CA, United States

Background: The use of next generation sequencing (NGS) to examine circulating HIV env variants has been limited due to env’s length (2.6kb), extensive indel polymorphism, GC deficiency, and long homopolymeric regions. We developed and standardized protocols for isolation, RT-PCR amplification, single-molecule real-time (SMRT®) sequencing, and haplotype analysis of circulating HIV-1 env variants to evaluate viral diversity in primary infection.

Methodology: HIV RNA was extracted from 7 blood plasma samples (1mL) collected from 5 subjects (one individual sampled and sequenced at 3 time points) in the San Diego Primary Infection Cohort between 3-33 months from their estimated date of infection (EDI). Median viral load per sample was 50,118 HIV RNA copies/mL (range: 22,387-446,683). Full-length (3.2kb) env amplicons were constructed into SMRTbell® templates without shearing, and sequenced on the PacBio RS II using P4/C2 chemistry and 180 minute movie collection without stage start. To examine viral diversity in each sample, we determined haplotypes by clustering circular consensus sequences (CCS), and reconstructing a cluster consensus sequence using a partial order alignment approach. We measured sample diversity both as the mean pairwise distance among reads, and the fraction of reads containing indel polymorphisms.

Results: We collected a median of 8,775 CCS reads per SMRT® cell (range: 4243-12234). A median of 7 haplotypes per subject (range: 1-55) were inferred at baseline. For the one subject with longitudinal samples analyzed, we observed an increasing number of distinct haplotypes (8 to 55 haplotypes over the course of 30 months), and an increasing mean pairwise distance among reads (from 0.8% to 1.6%, Tamura-Nei 93). We also observed significant indel polymorphism, with 16% of reads from one sample later in infection (33 months post-EDI) exhibiting deletions of more than 10% of env with respect to the reference strain, HXB2.

Conclusions: This study developed a standardized NGS procedure (PacBio SMRT®) to deep sequence full-length HIV RNA env variants from the circulating viral population, achieving good coverage, confirming low env diversity during primary infection that increased over time, and revealing significant indel polymorphism that highlights structural variation as important to env evolution. The long, accurate reads greatly simplified downstream bioinformatics analyses, especially haplotype phasing, increasing our confidence in the results. The sequencing methodology and analysis tools developed here could be successfully applied to any area for which full-length HIV env analysis would be useful.

Session P-B3
Thursday March 6, 2014, 2:30 PM–4:00 PM Exhibit Hall A
Viral Subtype: Expansion, Migration, and Recombination

223 Spread of CRF33_01B and Emergence of Novel Recombinants Among People Who Inject Drugs in Malaysia
Wei Zhen Chow1, Lai Yee Ong1, Hui Ting Cheong1, Nur Ezreen Syalina1, Maryam Nabil Al-Khannaq1, Yutaka Takebe2, Clayton Koh1, Haider Al-Darraji1, Adeeba Kamarulzaman1, Kok Keng Tee1
1Centre of Excellence for Research in AIDS (CERiA), Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia, 2AIDS Research Center, National Institute of Infectious Diseases, Toyama, Shinjuku-ku, Tokyo, Japan

Background: In Southeast Asia, continuous genetic diversification and active recombination involving circulating recombinant form, CRF33_01B and other circulating genotypes in the region including CRF01_AE and subtype B’s of Thai origin, may lead to the emergence of novel CRFs and unique recombinant forms. The history and magnitude of CRF33_01B transmission among various risk groups including people who inject drugs (PWID) however have not been investigated despite the possible epidemiological impact of CRF33_01B. Here, we update the most recent molecular epidemiology of HIV-1 among PWIDs and elucidate the epidemiological history of CRF33_01B among both high and low risk populations in Malaysia.

Methodology: Plasma samples were collected from a total of 356 consented HIV-positive PWIDs recruited among the prison inmates and attendees of a needle syringe exchange program in Malaysia between 2010 and 2011. The study population comprised 336 males and 20 females (mean age range: 31.3-44.7 years old). Population sequencing and phylogenetic analysis of gag-pol sequences were used to assess HIV-1 molecular epidemiology among
PWIDs. In addition, the past population dynamics of CRF33_01B was elucidated using maximum likelihood and the Bayesian Markov chain Monte Carlo (MCMC) sampling of CRF33_01Bpol sequences.

Results: HIV-1 CRF33_01B was circulating among 72% of PWIDs whilst a lower prevalence of other previously dominant HIV-1 genotypes [subtype B’ (11%) and CRF01_AE (5%)] and CRF01_AE/B’ unique recombinants (10%) were detected, indicating a significant shift in genotype replacement. Three clusters of CRF01_AE/B’ recombinants displaying divergent yet phylogenetically-related mosaic genomes to CRF33_01B were characterized, suggestive of an abrupt emergence of multiple novel CRF clades among PWIDs. We showed that the founder lineages of CRF33_01B were likely to have first emerged among PWIDs in the early 1990s before spreading exponentially to various populations (including children who acquired infections from their mothers) and became endemic around the early 2000s.

Conclusions: Our findings provide notable genetic evidence indicating the widespread expansion of CRF33_01B among PWIDs and into the general population. The emergence of novel recombinant clades highlights the escalating genetic complexity of HIV-1 in the Southeast Asian region.

224 AHI Detection Among People Who Inject Drugs in Russia Reveals the HIV-1 Transmission Bottleneck
Elena Dukhovlinova1, Alksey Masharsky2, 3, Sergei Verevchikov2, Olga Toussova1, 4, Andrey Shevchenko2, 5, David Montefiori6, Irving Hoffman7, William Miller8, Andrei Kozlov9, 10, Ronald Swanstrom11, 12
1CFAR and Lineberger CCC, University of North Carolina, Chapel Hill, NC, United States, 2Saint Petersburg State University, Saint Petersburg, Russian Federation, 3Department of Zoology, University of Oxford, Oxford, United Kingdom, 4Lancet Laboratories, Johannesburg, South Africa, 5Department of infectious Diseases, University of North Carolina, Chapel Hill, NC, United States, 6Gillings School of Global Public Health, University of North Carolina, Chapel Hill, NC, United States, 7Department of Biochemistry and Biophysics, University of North Carolina, Chapel Hill, NC, United States

Background: The expansion of the HIV-1 epidemic in Russia is mostly among people who inject drugs (PWID) due to unsafe injection practices with parental transmission. A pilot study to determine the feasibility of detecting acute HIV infection in PWID in St. Petersburg, Russia was conducted in 2011. Here we report the results of the molecular analysis of longitudinal blood samples obtained from the acutely infected IDUs and their risk network partners.

Methodology: We performed phylogenetic and BEAST analysis of the SGA-derived full-length env genes of acutely infected IDUs to estimate the multiplicity of HIV-1 infection. The AHI participants were also followed for up to 12 months with the weekly blood draws in the first month post-infection. We included single blood samples of the network members into the analysis to determine possible in-network transmission events. We analyzed the behavioral data provided by the subjects to suggest the parental or sexual transmission. We also created a panel of pseudoviruses derived from the HIV-1 strains of AHI and chronically infected subjects to test for the neutralization sensitivity of the virus.

Results: We obtained single env genes for 32 cDNAs samples from the blood of 7 AHI subjects and 8 members of their risk network. All sequences represented region-specific subtype A strains. We identified 3 potential transmission clusters: two included the chronically infected subject, and one was an AHI-to-AHI case. For all of the AHI subjects including those who were suggested to have predominantly injection risk of HIV-1 acquisition we confirmed that a single variant established each HIV-1 infection. We detected superinfection and subsequent recombination of the diverse strains in one subject. Combining these data with our previously described findings, we have found that in 14 out of 19 (74%) IDU cases HIV-1 infection was initiated by the single viral variant, including all the suggested injection-related transmission cases (total of 8). The neutralization sensitivity assay of transmitted vs persistent strains of HIV-1 subtype A is under study.

Conclusions: Similar to the sexual route of infection, injection drug use in St. Petersburg, Russia, is associated with single-variant HIV transmission. High HIV-1 incidence and prevalence, low genetic diversity and a transmission bottleneck make this population a good candidate for preventive HIV-1 vaccine trials.

225 Migration of HIV-1 Subtypes in East Africa Is Associated With Proximity To Highway Corridor
Nuno R. Faria1, Kim C. E. Sigaloff2, David A. M. C. van de Vijver3, Andrew J. Tatem4, Andrea C. Pinelas5, Carole L. Wallis6, Marc A. Suchard7, Tobias F. Rinke de Wit8, Raph L. Hamers9, Philippe Lemey4, Nicaise Ndombi10
1Department of Zoology, University of Oxford, Oxford, United Kingdom, 2Department of Global Health, PharmAccess Foundation, Academic Medical Center of the University of Amsterdam, Amsterdam, Netherlands, 3Department of Virology, Erasmus Medical Center, Rotterdam, Netherlands, 4Department of Geography and Environment, University of Southampton, Southampton, United Kingdom, 5Department of Microbiology and Immunology, Rega Institute for Medical Research, Leuven, Belgium, 6Lancet Laboratories, Johannesburg, South Africa, 7Department of Biomathematics and Human Genetics, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, United States, 8Institute of Human Virology, Baltimore, MD, United States

Background: Epidemiological processes such as migration and population structure leave a measurable imprint into HIV gene sequences that can be recovered using phylodynamic approaches. Empirical evidence suggests that HIV-1 migration in east Africa is determined by spatial accessibility, a measure of human mobility that summarizes transport availability and quality.

Methodology: Here, we use a large comprehensive set of nucleotide sequences that span most HIV-1 genetic diversity in this region and apply a recently developed Bayesian phylogeographic model to assess and quantify the contribution of several potential drivers underlying viral migration. We further investigate the most significant pathways of HIV-1 dispersal and examine spatial structure among locations along the northern highway, the most active transportation axis in this region.

Results: We tested the contribution of potential predictors of HIV-1 migration among 17 east African locations along Burundi, Democratic Republic of Congo, Kenya, Rwanda, Republic of Tanzania and Uganda. We find that spatial proximity to the northern highway is the single best predictor of HIV-1 migration in the region, with substantial statistical support in favour of including this predictor in the process model (Bayes Factor = 64.41). Viral migration was not significantly associated with spatial accessibility, pairwise geographic distances, train transportation network data, population changes nor with distances to the central highway, another transportation axis in the region. These findings were robust to the inclusion of sampling efforts for each location.
Also, nearly half of the significant viral migration pathways (47%, 30/64) involved locations situated along or nearby the northern highway. For all subtypes, viral exchange between locations along this highway was significantly higher as compared to locations remote from this highway axis.

**Conclusions:** We offer a statistical quantification of HIV-1 drivers in a high prevalence sub-Saharan region. Our high-resolution phylodynamic approach allowed to fine-tune previous findings and supports that HIV-1 migration in east Africa is mostly determined by viral exchange among populations that travel or live along or in the vicinity of the northern highway transport corridor. This approach is applicable to other scales or regions and highlights the potential for quantitative large-scale phylogenetic analyses in public health.

226 Ongoing Cross-Species Transmission of Simian Retroviruses and High HIV Prevalence in Cameroon
Julius Chia1,2, Avelin Aghokeng1,2, Emilande Guichet3, Ahidjo Ayoub2, Steve Ahuka-Mundeke2, Nicole Vidal4, William Switzer5, Eric Delaporte6, Etel Mpoudi Ngole7, Martine Peeters8
1Projet PRESICA and IMPM/CREMER, Yaoundé, Cameroon, 2IRD, Montpellier, France, 3Centers for Disease Control and Prevention, Atlanta, GA, United States

**Background:** Recent studies have shown ongoing exposure of humans to a wide variety of simian retroviruses, including SIVs, HTLVs and SFVs. Moreover, the recent descriptions of HIV-1 group P in Cameroon, and HIV-2 group I in Ivory Coast, confirm that our knowledge on HIV diversity is still incomplete. Here, we studied retroviral infections in humans living in rural forest areas in southern Cameroon, to further explore other transmissions to humans as well as the extent of the HIV epidemic in these areas.

**Methodology:** A total of 3288 blood samples were obtained from adults in 26 villages. All samples were tested for the presence of HIV antibodies using commercial assays, and a subset of individuals with highest probability of exposure to non-human primates were tested for the presence of SIV and SFV antibodies by an in-house xMAP assay. HTLV antibodies were detected by commercial Elisa. HIV, SIV, SFV and HTLV antibody positive samples were tested by PCR and sequence analysis to confirm and characterize retroviral infection; RT and protease (1800 bp) for HIV, integrase for SIV (300 bp) and SFV (425 bp), tax (200 bp) and/or LTR (450-900bp) for HTLV.

**Results:** In this rural forest areas, the overall HIV prevalence ranged between 6% and 9%, and was at least two times higher in women as compared to men, reaching 20% in women aged between 25 and 34 years. All HIV infections were HIV-1 group M. Genetic characterization of 188 HIV-1 strains showed predominance of CRF02_AG (58%), 12 other subtypes/CRFs, URFs (10%) and two new possible CRFs. Importantly, 13 transmission clusters (20% of HIV-1 strains) including 2 to 10 strains in were observed. Only 3 clusters comprised HIV-1 strains from 1 women and 1 man. In the other clusters, strains derived from women predominated, with one cluster of 10 strains exclusively from women, residing in 4 different villages on a major road for logging transport. HTLV infection was confirmed by PCR in 30/2501(1.2%) individuals in Cameroon, prevalences were similar among women and men but increased with age from 0.7% (18-24y) to 1.8% (>45y). HTLV subtype B predominated, but a new HTLV-1 subtype F and HTLV-3 B variant related to STLVs from local NHPs were observed. Although, 23 on a subset of 813 samples reacted weakly with SIV antigens, no virus was amplified by PCR. Among 69 SFV antibody reactive samples, only one SFV infection with a chimpanzee virus, was confirmed by PCR in a 65 years old male reporting hunting.

**Conclusions:** Although no SIV infections were observed in rural forest areas from Cameroon where humans are exposed to NHPs, our study clearly shows contemporary transmission of simian retroviruses. The high HIV prevalence and high rates of transmission clusters in these rural areas indicate that, if a new SIV crosses the species barrier, conditions for rapid spread are present.

227 An Emerging HIV-1 Recombinant (CRF58_01B) Disseminating Among People Who Inject Drugs in Malaysia
Wei Zhen Chow1, Yuutaake Takebe2, Nur Ezreen Syafina3, Malavelli Soorya Prakasa4, Haider Al-Darraji5, Clayton Koh6, Adeeba Kamarulzaman7, Kok Keng Tee8
1Centre of Excellence for Research in AIDS (CERIA), Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia, 2National Institute of Infectious Diseases, AIDS Research Center, Toyama, Shijuku-ku, Tokyo, Japan

**Background:** The HIV epidemic is characterised by the circulation of HIV-1 group M (main) comprising of 11 subtypes and sub-subtypes and to date 55 circulating recombinant forms (CRFs). In Southeast Asia, active inter-subtype recombination involving three main circulating genotypes - subtype B (including subtype B'), CRF01_AE and CRF33_01B, have contributed to the emergence of novel unique recombinant forms. Here we report the characterisation of a novel CRF candidate among people who inject drugs in Malaysia, designated as CRF58_01B by the Los Alamos National Laboratory.

**Methodology:** A molecular epidemiological surveillance of HIV-1 gag-RT genes were conducted among 258 people who inject drugs (PWIDs) in Kuala Lumpur, Malaysia between 2009 and 2011 whereby a novel CRF candidate was identified among six epidemiologically unlinked male subjects (mean age range: 33.6-47.4 years old) from various ethnic groups. HIV-1 near full length genome (≈9kb) was amplified by nested PCR in ten overlapping fragments using primers as previously described, sequenced and assembled prior to alignment, phylogenetic and bootscanning analyses to define the recombinant structures. Sub-region tree analysis was further used to determine the parental origin of each region.

**Results:** Near full length genomes sequenced in six epidemiologically unlinked individuals (09MYPR37, 10MYJK036, 10MYPR87, 11MY1Z731, 11MY1R704 and 11MY1EP794) showed identical mosaic structures consisting of subtype B' and CRF01_AE, with six unique recombination breakpoints in the gag-RT, pol and env regions. Among the high-risk population of PWIDs in Malaysia which was predominantly infected by CRF33_01B (>70%), CRF58_01B circulated at a low but significant prevalence (2.3%, 6/258). Interestingly, the CRF58_01B shared two unique recombination breakpoints with other established CRFs in the region: CRF33_01B, CRF48_01B and CRF53_01B in the gag gene, and CRF15_01B (from Thailand) in the env gene. Discrete Bayesian Markov chain Monte Carlo sampling analysis showed that CRF58_01B and other recently discovered CRFs were most likely to have originated in Malaysia, and that the recent spread of recombinant lineages in the country had little influence from neighbouring countries.

**Conclusions:** Our recent findings signify the increasingly complex HIV-1 diversity in Southeast Asia that may hold an implication on disease treatment, control and prevention.
228 Exploring the Hidden Interrelationship of HIV-1 Epidemics in Asia and Beyond
Yutaka Takebe1, Makiko Kondo2
1AIDS Research Center, National Institute of Infectious Diseases, Tokyo, Japan, 2Department of Microbiology, Kanagawa Prefectural Institute of Public Health, Chigasaki, Japan

Background: Along with the resurgence in HIV infection among men who have sex with men (MSM) in the Western world, there have been reports of emerging or newly-identified HIV epidemics among MSM in Asia. Especially, epidemics among MSM in China continued to expand rapidly. Recently, China witnessed the dramatic shift in HIV-1 genotype distribution among MSM from subtype B to CRF01_AE. CRF01_AE strains responsible for China’s MSM epidemics were found to be classified into two distinct variants (designated CN.MSM.01-1 and CN.MSM.01-2). Both variants accounted for 95% of CRF01_AE infections among MSM in China. We aim to examine the possible effect of China’s expanding epidemics among MSM in the surrounding regions and the rest of the world.

Methodology: Using Los Alamos HIV sequence database (HIVDB) and the in-house HIVDB for Tokyo-Kanagawa metropolitan area in Japan, we explored the possible interplay of the epidemics in the region and the rest of the world, by means of Basic Local Alignment Search Tool (BLAST) search coupled with subsequent phylogenetic tree analyses with the nucleotide sequences of 1.1-kb pol (pro-RT). The timescale of the emergence of various MSM lineages was estimated by Bayesian molecular clock analyses.

Results: Extensive database survey revealed that Chinese CRF01_AE variants occurred in surrounding regions in Asia [Hong Kong (n=19); Thailand (n=3); Japan (n=4)] as well as in the rest of the world [Germany; USA (n=1 each)]. The variants detected among MSM in Japan (4 of 4) and Hong Kong (17 of 19) formed distinct phylogenetic subclusters within CN.MSM.01-1 (JP-CN.MSM.01-1) and CN.MSM.01-2 (HK-CN.MSM.01-2), revealing remarkable founder effects. Evolutionary analyses indicated that the emergence of CN.MSM.01-1 and CN.MSM.01-2, JP-CN.MSM.01-1 and HK-CN.MSM.01-2 was estimated to be ~1997, ~1999, ~2009 and ~2005, respectively.

Conclusions: Our study demonstrates for the first time the effect of the expanding HIV epidemic among MSM in China on transmission in neighbouring countries and the rest of the world. This finding highlights the importance of strengthening HIV monitoring efforts in a global scale and the urgent need for implementing effective measures to reduce HIV transmission among high risk groups in Asia, especially as HIV prevalence in China grows and socio-economic links between China and the rest of the world continue to expand.

229 CRF01_AE and Subtype B Transmission Networks Cross Over; A New AE-B Recombinant Emerges in Japan
Masumi Hosaka1, Seiichiro Fujisaki2, Jurko Hattori1, Teiichiro Shiino1, Atsuko Hachiya1, Masakazu Matsuda1, Yasumasa Iwata1, Yoshiyuki Yokomaku1, Wataru Sugiuura1
1National Hospital Organization Nagoya Medical Center, Nagoya, Japan, 2National Institute of Infectious Diseases, Tokyo, Japan, 3Nagoya Graduate School of Medicine, Nagoya, Japan

Background: The major circulating HIV-1 subtypes in Japan have been B followed by CRF01_AE, with prevalences of 86% and 7% in newly diagnosed HIV/AIDS cases, respectively. These two strains have distinct epidemiological characteristics; B predominates in men who have sex with men (MSM), whereas AE is observed mostly in heterosexuals (Hattori 2010). However, transmission networks of these two risk populations appear to be crossing over and diffusing. We have recently seen more AE cases among MSM in Japan, suggesting an increasing chance of recombination between the two strains in Japan. Indeed, newly diagnosed populations have had more discrepant subtyping results between pol and env regions. In this study we explored possible AE-B recombinations and transmission networks in Japan.

Methodology: Newly diagnosed HIV/AIDS cases that visited Nagoya Medical Center from June 1997 to March 2012 were enrolled in the study. We sequenced and analyzed three regions, gag p17 (396bps), protease-rt (1017bps), and env C2V3 (222 bps). Subtypes of each region were determined by phylogenetic analysis with reference sequences from Los Alamos database. Cases with discordant subtype results among the 3 regions were suspected as recombinant strains, and their near full-length sequences were determined. To clarify recombinant structures, we performed similarity plotting, boot-scanning and informative site analysis.

Results: Among 1070 cases diagnosed as HIV/AIDS during the study period, suspected AE-B recombinant form, where gag was identified as AE, pol as B, and env as AE, were found in 7 cases with their time of diagnosis ranging from 2003 to 2010. Of these, 5 were Japanese MSM and 1 was a heterosexual male. Detailed analysis clarified that 6 cases shared identical recombinant structure, different from any previously reported AE-B recombinant strains and was designated as CRF69_01B by the Los Alamos HIV sequence database. tMRCA analysis estimated CRF69_01B emerged between 1993 and 1997, soon after CRF01_AE was introduced from neighboring countries in mid 1990s.

Conclusions: A new recombinant strain composed of CRF01_AE and subtype B, CRF69_01B, was identified in Japan. Although the majority of AE- and B-infected cases belong to different risk populations and transmission networks, the emergence of the recombinant strain indicates the two networks are not sequestered and connections exist. As nine circulating recombinant forms composed of AE and B (CRF15, 33, 34, 48, 51, 52, 53, 54, and 55) have been reported in neighboring countries, it appears that the two strains have higher affinity of recombination. Thus, stakeholders can anticipate the emergence of further recombinant strains, emphasizing the need for continuous surveillance to understand HIV transmission in Japan and neighboring countries.
Phylodynamic Analysis of a Regional HIV Epidemic

**Medicine, BC Centre for Excellence in HIV/AIDS, Vancouver, BC, Canada**

**Background:** Understanding the processes shaping epidemics is critical for their prediction and management. Phylogenetic inferences drawn from viral sequence data can provide a window into the temporal dynamics of regional epidemics, allowing estimation of rates of incidence, infection accumulation, and viral population demographic history. Within such regional epidemics, different risk factors in transmission dynamics and health care engagement predict contrasting different viral evolutionary dynamics measurable from the shape of phylogenetic trees.

**Methodology:** We inferred 1,000 time-scaled phylogenetic trees for 27,296 HIV protease and RT sequences sampled from 7,747 patients in the BC Centre for Excellence in HIV/AIDS database in BC, Canada. All sequences were doubly anonymized to protect patient privacy. Estimates of epidemic age were calculated using the root age of each phylogenetic tree in our distribution. We visualized the accumulation of infections through time using lineage through time plots (LTT). We utilized maximum likelihood approaches for estimating rates of incidence and effective population size by fitting birth-death models across our distribution of phylogenetic trees for the epidemic as a whole and within risk factors.

**Results:** Our analysis suggested 1897 (IQR: 1883-1923) as the estimated median time for the origin of the HIV epidemic overall, and 1941 (IQR: 1923-1958) for the subtype B clade. LTT plots reveal that within and between HIV subtypes, the BC epidemic is composed primarily of variation originating prior to 1990 (the advent of health care intervention). Birth-death models show the subtype B epidemic has undergone a recent decrease in the estimated rate of incidence. Skyline plots show corresponding declines in effective population size towards the present. Results are consistent with an epidemic founded by multiple sources and subsequent spread along local networks corresponding to different HIV risk factors, with later declines in spread.

Comparative phylogenetic analyses among risk exposure categories reveal substantial differences in the timing of the HIV epidemic between intravenous drug users (IDU) and MSM. IDU experienced a dramatic increase in rate of lineage accumulation; incidence and effective population size in the mid-1990s whereas the MSM epidemic underwent rapid growth in the 1980’s followed by subsequent tapering off.

**Conclusions:** Concordance of our population-level phylogenetic results with epidemiological data validates the use of phylogenetic methods in assessing the past and present dynamics of the HIV epidemic. Further, we show the potential of comparing inferences drawn from phylogenetic trees partitioned by different HIV risk exposure categories.

Damage of Gut Junctional Complexes Features HIV-Infected Immunological Non Responders

**Camilla Tincati**, Giuseppe Ancona1, Paola Braidotti, Delfina Tosi, Federica Savi, Elisa Borghi, Alessandra Barassi, Esther Merlini, Nicolas Chomont, Giulia Marchetti

1Department of Health Sciences, University of Milan, Milan, Italy. 2Vaccine and Gene Therapy Institute, Port St. Lucie, FL, United States

**Background:** Gastrointestinal (GI) integrity/permeability were investigated as mechanisms for T-cell activation and poor immune recovery during cART (Immunological Non Responders, INR).

**Methodology:** HIV+ patients (pts) on suppressive cART for at least 12 months were enrolled. 21 INR (ΔCD4 <30% and/or CD4 <350/uL) were compared to 29 Full Responders (FR). GI permeability (LAC/MAN test), stool microbiome (DGGE), plasma MT (LPS, sCD14, EndoCab) and T-cell distribution (flow cytometry) were analyzed. 13 FR and 8 INR also underwent colonoscopy with colon and ileum biopsies for immunohistochemical (IHC) evaluation of adherens/tight junction proteins (CDh1, ZO-1, Claudin1 and 7), cell proliferation (Ki67), T-cell tissue count (CD3, CD4, CD8) and electron microscopy (EM) study of paracellular spaces. Anatomopathological (AP) findings were compared to those of 5 HIV- controls. Total (THIV-DNA), integrated HIV-DNA (iHIV-DNA) and 2-LTR circles were quantified by Real-Time PCR in colon/ileum biopsies and in blood isolated CD4 T-cells.

**Results:** INR presented reduced naïve CD4+CD45RA+ (p <.01) and CD4+CD127+ (p <.001) and increased activated CD8+CD38+ (p <.03) and CD8+CD38+RO+ (p <.03). INR and FR displayed comparable ileum and colon expression of CD3, CD4 and CD8. INR showed higher Ki67 colon expression (35%, IQR 30-40 vs 25%, IQR 9-30; p =.02). CDh1 and ZO-1 immunoreactivity were impaired in HIV+ pts vs controls. CDh1 immunostaining was distributed around the entire epithelial plasma membrane in controls, at the basolateral surface in FR and only at the basal level in INR. The lowest levels of CDh1 cells were detected in colon biopsies from INR. Moreover, ZO-1 expression was frequently negative in ileum and colon tissue from INR. EM evaluation of the colon confirmed wider intercellular spaces in INR (Fig). DGGE demonstrated clustering stool microbial communities in INR not detected in FR. Both INR and FR showed a heightened LAC/MAN ratio (>0.045) suggesting increased GI permeability; however, no significant differences in LAC/MAN and plasma LPS, sCD14, EndoCab were noted between groups.

No differences in THIV-DNA, iHIV-DNA and 2-LTR in circulating CD4 and colon/ileum tissue were registered between FR and INR.

**Conclusions:** Patients failing CD4 recovery on effective cART present damage of gut junctional complexes seemingly not due to increased viral burden. Such defects may translate into impaired mucosal and peripheral immunity, hampering CD4 reconstitution, albeit GI CD4 repopulation.
A, C: Colon biopsy from a representative INR patient. A: CDh1 antibody, arrow points to negative lateral edge of enterocytes. 40X original magnification (OM). C: arrows point to dilated intercellular space. 30,000X (OM). B, D: Colon biopsy from a representative FR patient. B: CDh1 antibody, arrow points to lateral immunoreactivity of enterocytes. D: arrows point to normal intercellular space. 30,000X (OM). E, F: CDh1 and ZO-1 expression in the ileum of study patients. G, H: CDh1 and ZO-1 expression in the colon of study patients. Immunoreactivity was evaluated by staining intensity (1 to 3) and percentage of positive cells.

**Dysregulated Gut Dendritic Cells Correlate With T-Cell Activation During Untreated HIV Infection**

**Stephanie M. Dillon**<sup>1</sup>, Eric J. Lee<sup>1</sup>, Gregory L. Austin<sup>1</sup>, Sara Gianella<sup>2</sup>, Davye M. Smith<sup>2</sup>, Basile Siewe<sup>3</sup>, Cara C. Wilson<sup>1</sup>

<sup>1</sup>University of Colorado AMC, Aurora, CO, United States, <sup>2</sup>University of California San Diego, La Jolla, CA, United States, <sup>3</sup>Rush University Medical Center, Chicago, IL, United States

**Background:** The gut mucosa is a major site of HIV-1-associated pathogenesis. Dendritic cells (DCs) play crucial roles in innate and adaptive immunity, in gut homeostasis and in pathogen defense, but the impact of HIV-1 infection on gut DCs has not been extensively studied. We investigated the impact of chronic, untreated HIV-1 infection on colon DC frequency and activation and evaluated associations with virological and immunological parameters.

**Methodology:** Colonic mucosal cells (CMC) and peripheral blood (PB) mononuclear cells were obtained from 24 untreated HIV-1 infected (HIV-1+; median viral load (VL): 51,350 HIV-1 RNA copies/ml; median CD4 T cell count: 445 cells/μl) and 14 uninfected (HIV-1 neg) subjects. Participants gave informed consent. Flow cytometry was used to determine frequencies (number per gram of mucosal tissue) of colon CD11chi HLA-DR + myeloid DC (mDC) subsets (CD1c+ and CD1c neg) in conjunction with increased levels of CD40 on CD1c + (p=0.006) and CD1c neg (p=0.005) mDCs. The fraction of CD83+ pDCs were also reduced (p=0.03), but levels of CD40 on pDCs were similar to HIV-1neg donors. In HIV-1+ donors, CD40 expression on CD1c+ mDCs correlated with mucosal VL (r=0.49, p=0.04), with the number of activated colon CD4 (r=0.70, p=0.0009) and CD8 (r=0.59, p=0.008) T cells, with CMC production of pro-inflammatory IL-1β (r=0.72, p=0.003), IL-23 (r=0.67, p=0.008), IL-6 (r=0.68, p=0.006), TNF-α (r=0.66, p=0.009) and regulatory IL-10 (r=0.54, p=0.04), and with the percent of activated PB CD4 (r=0.61, p=0.006) and CD8 (r=0.53, p=0.02) T cells. No associations between activated DCs and PB CD4 count or plasma VL were observed.

**Conclusions:** Untreated, chronic HIV-1 infection results in a dysregulated colon mDC phenotype characterized by a lower percentage of CD83+ mDCs, but increased expression of CD40. Increased CD1c+ mDC activation was associated with local T cell activation, higher mucosal HIV-1 viral load, and with mucosal cytokine production. Further, CD1c+ mDC activation was associated with higher levels of systemic T cell activation, thereby linking colon mDC activation to a marker of HIV-1 disease progression. Together, these findings suggest gut mDCs likely contribute to mucosal inflammation and HIV-1 pathogenesis.

**HIV-1 RNA+ Cells Are Concentrated in the Germinal Centers of Activated Lymph Nodes In Vivo**  
Tessa Arends1, Joy Folkvord1, Martin McCarter2, Amie Meditz2, Elizabeth Connick1  
1University of Colorado Anschutz Medical Campus, Aurora, CO, United States, 2Boulder Community Hospital, Boulder, CO, United States  

**Background:** Follicular dendritic cells (FDC) are located within germinal centers (GC) of follicles and harbor large amounts of extracellular virus that are potently infectious to CD4+ T cells in vitro. Although most HIV-producing T cells are located within B cell follicles in secondary lymphoid tissues, it is unknown whether HIV RNA+ cells are concentrated within GC in vivo. The purpose of this study was to quantify HIV RNA+ cells in GC, non-GC follicular (non-GC F) and extra-follicular (EF) compartments of lymph nodes (LN) of HIV-infected individuals. We hypothesized that if FDC are a major source of infectious virus in vivo, then HIV RNA+ cells will be concentrated primarily within GC.  

**Methodology:** Frozen LN cross-sections from 22 chronically HIV-infected untreated individuals without AIDS and 10 HIV-seronegative individuals were evaluated. For each LN, **in situ** hybridization for HIV RNA combined with immunohistochemical (IHC) staining for CD20 and IgD were performed in a minimum of 3 cross-sections located ~60 μm apart. GC was defined as CD20+ IgD+ stained areas, non-GC F as CD20+ IgD+, and EF as CD20- IgD+. Visual inspection and quantitative image analysis were used to determine the number of HIV RNA+ cells per mm². IHC for HIV p24 Ag was used to identify the FDC reservoir of virions in follicles (CD20+). Wilcoxon two-sample t test was used for comparisons. Spearman ρ was used to describe correlations.  

**Results:** LN cross-sectional area was larger in HIV+ (median, 35.8 mm²) compared to HIV- subjects (median, 15.4 mm²; p=0.06). Percent LN that was GC was 16-fold higher in HIV+ (median, 8%; range 0.8-41%) than HIV- (median, 0.5%; range, 0-1.6%). Frequencies of HIV RNA+ cells in LN were higher in GC (median, 2.95 cells/mm²) than in non-GC F (median, 1.38 cells/mm²; p = 0.0008) and EF (median, 0.13 cells/mm²; p< 0.0001). A median of 55% of HIV RNA+ cells within LN resided in GC, which was 2.5-fold higher than both non-GC F (median, 22%; p=0.0012) and EF (median, 22%; p= 0.0005). Plasma HIV RNA correlated with HIV RNA+ cells/mm² in GC (ρ=0.62, p=0.002), non-GC (ρ=0.65, p=0.001) and EF (ρ=0.83, p<0.0001). Percent p24 Ag+ area within follicle ranged from 0.1 to 4.1 (median, 0.8), but did not correlate with either plasma HIV RNA (p=0.13) or frequency of HIV RNA+ cells in GC (p=0.56).  

**Conclusions:** This study is the first to quantify the distribution and frequency of HIV-1 producing cells within GC of LN. HIV RNA+ cells are concentrated within GC of activated follicles where FDC and their extra-cellular burden of HIV virions are located. Results are consistent with the hypotheses that FDC are major sources of infectious virus in vivo and/or GC F follicular helper cells are highly permissive to HIV.

**Duodenal and Rectal Mucosa Immune Reconstitution Differ After ART Initiation**  
Talia Sainz1, Sergio Serrano-Villar1, Anthony Albanese2, Tammy Yotter3, Paolo Troia-Cancio4, Darin Lartimore4, Steve Deeks4, Elizabeth Sinclair4, Vera Go4, David Asmuth5  
1Molecular Immune-Biology Laboratory, Hospital General Universitario Gregorio Marañón, Madrid, Spain, 2Infectious Diseases Department, Hospital Universitario Ramón y Cajal, Madrid, Spain, 3Veterans Administration Northern California Health Care System, Sacramento, CA, United States, 4University of California Davis Medical Center, Sacramento, CA, United States, 5UCSF, San Francisco, CA, United States  

**Background:** Despite peripheral immunological recovery, incomplete restoration of the gut associated lymphoid tissue (GALT) during treated HIV infection is likely a major determinant of disease progression. The association between blood and GALT T-cell changes following ART initiation, and whether these changes correlate across the different gastrointestinal tract segments remain unknown.  

**Methodology:** Peripheral blood (PB), duodenal and rectal biopsies were obtained from 11 HIV- controls and 33 ART naïve HIV+ subjects participating in a randomized clinical trial comparing three different ART initiation strategies, at baseline and after 9 months of treatment. Tissue was digested into single-cell suspensions for measurements of T-cell subsets and activation phenotype by immunophenotyping  

**Results:** Twenty-six HIV+ subjects completed the follow-up. Median age was 37 years [25-42] vs 34 [28-43] in the control group, and median CD4 T-cell count 435 cell/mL [283-572], Eight subjects received EFV, 10 MRV and 8 MVC+RAL, each in combination with FTC/TDF, and all achieved viral suppression.  

Overall, ART resulted in a significant repletion of CD4 T-cell in GALT at month 9, greater in rectum (24% to 38%) than in duodenum (12% to 17%) (all P<0.01). Also, CD8 T-cells decreased in rectum (62% to 53%) and duodenum (81% a 70%) (all P<0.01). However, the levels of both CD4 and CD8 T-cells remained very impaired relative to controls (beyond 2 SD). Changes in %CD4 in PB (24% to 40%, P<0.01) predicted %CD4 changes in colon (Beta 0.54, P=0.023) but not in duodenum (Beta -0.19, P=0.272).  

The %HLADR+CD38+ of CD8 T-cells was significantly higher at baseline in PB and rectal mucosa in HIV+ compared to HIV- subjects, but not in duodenum. CD8 T-cell activation significantly decreased in blood (57% to 28%, P<0.001), duodenum (65% to 52%, P=0.015) and rectum (71% to 58%, P=0.429,) and the change in PB was reflective of the smaller mucosal changes (duodenum Beta=-0.39, P<0.01, and rectum Beta=0.23, P<0.01). However, the % of activated CD8 T-cells in PB and in colon did not reach normal levels. In addition, the % of PB activated CD8 T-cells at baseline predicted the extent of CD4 depletion in duodenum (Beta=-0.7, P<0.001) and colon (Beta=-0.7, P<0.001).  

HIV+ subjects showed similar % of naive CD8+ T-cells in colon and duodenum than controls, but not in PB. The CD8 naive/memory ratio significantly improved in blood but did not reach normal levels.  

**Conclusions:** Following ART initiation we observed incomplete recovery of GALT CD4 T-cells. Immune reconstitution of the duodenal mucosa was impaired compared to changes in blood and rectum. The duodenal compartment may represent a portal for systemic immune activation and CD4 depletion during HIV infection and further studies of this compartment are warranted.
**Gut Microbiota of HIV Infected Subjects Induce Inflammatory Cytokines But Not T Regulatory Cells**

**Authors:** Charles P. T. Neff, Andrew Fontenot, Catherine Lozupone, Brent E. Palmer

**Institution:** Allergy and Clinical Immunology, University of Colorado, Aurora, CO, United States

**Background:** We co-exist with an abundant microbiota that cooperate with and help regulate our immune system. However, during HIV infection the microbial community in the gut is altered to a distinctive composition which is not consistently restored to that of seronegative subjects by ART. Recently, our group illustrated that in contrast to uninfected patients, the microbial community in HIV infected subjects exhibits increased phylogenetic diversity and is Prevotella-rich and Bacteroides-poor. Here we seek to understand the impact of the change in gut microbiota on HIV infection by characterizing innate and adaptive immune responses, including T regulatory cells, to selected gut bacteria that changed with HIV infection.

**Methodology:** Based on our 16S rRNA sequencing from HIV+ and HIV- subjects we chose four characteristic bacteria; Bacteroides dorei, Bacteroides fluxus, which were decreased, and Prevotellaceae copri, Erysipelotrichaceae biforme, which were elevated with HIV infection. PBMCs of 15 HIV-positive and 18 HIV-seronegative subjects were incubated with lysate of these bacteria. Levels of inflammatory cytokines were evaluated at 24 hours post inoculation by bead array assay, and T regulatory cells and CD4+ T cell proliferation were enumerated by flow cytometry at either 3 or 6 days. Statistical significance was determined using Mann-Whitney T tests.

**Results:** HIV-infected subjects had significantly elevated levels of both TNF-α and IL-10 to all bacteria in comparison with HIV-seronegative (p<0.05). Levels of T regulatory cells also increased with all bacteria although levels were not significantly different in regard to HIV status. Median levels of T regulatory cells from PBMC cultured with B. fluxus (2.24%) and B. dorei (2.08%) were greater compared to that of P. copri (0.44%; p=0.03, p=0.05, respectively) and E. biforme (0.06%; p=0.02, p=0.03, respectively). All bacteria induced CD4+ T cell proliferation regardless of HIV status. However, with HIV infection CD4+ T cell proliferation to B. fluxus (1.30%) and B. dorei (0.47%) was reduced compared to HIV-seronegative subjects (4.77% and 1.78%; p=0.03, p=0.08, respectively), while responses to P. copri and E. biforme were not significantly different.

**Conclusions:** These results illustrate that HIV infection is associated with a distinct microbial signature that is more pro-inflammatory. Furthermore, Bacteroides species which are lost during HIV infection are better adapted for inducing T regulatory cells than P. copri and E. biforme that are enriched in the gut during infection. By evaluating bacterial mediated immune responses these studies will provide important new understanding about the mechanisms and functional aspects of these bacteria in regulating the immune system and their role in HIV disease.

---

**An SMS Intervention To Improve HIV Linkage To Care: A Randomized, Comparative Effectiveness Trial**

**Authors:** Mark J. Siedner, Data Santorino, Alexander J. Lankowski, Michael Kanyesigye, Bosco Mwebesa Bwana, Jessica E. Haberer, David R. Bangsberg

**Institution:** 1Medicine, Massachusetts General Hospital, Boston, MA, United States, 2Mbarara University of Science and Technology, Mbarara, Uganda, 3University of Philadelphia, Philadelphia, PA, United States, 4Mbarara University of Science and Technology, Mbarara, Uganda

**Background:** Up to 50% of HIV-infected persons in sub-Saharan Africa are lost from care between HIV diagnosis and ART initiation. Clinicians identified patients undergoing high-risk CD4 testing, defined as a test for which an abnormal result would prompt early return to care. Participants enrolled in the pre-intervention period (January-August 2012) served as a control group. Participants enrolled in the intervention period (September 2012-November 2013) received an SMS message notifying them of normal results or, if results were abnormal, were randomized to one of three messages: 1) an unprotected SMS reporting an abnormal result (direct message); 2) a personal identification number-protected (PIN) message; or 3) a message reading “ABCDEFG”, coded to convey an abnormal result confidentially. We provided transportation reimbursements (~$6USD) to those returning within 7 days of their first abnormal result SMS. We conducted survival analyses and fit Cox proportional hazards regression models to estimate differences between groups for outcomes of interest: 1) time to return to clinic after an abnormal result and 2) time to initiation of ART among the ART naïve.

**Results:** Of 553 patients enrolled, 533 (96%) had a valid laboratory result, and 187 (35%) of results were abnormal. There were 46, 48, 47, and 45 participants with abnormal laboratory results in the control, direct, PIN, and coded message groups. Median days to clinic return after abnormal results in the control, direct, PIN, and coded groups was 29, 4 (P<0.001 for logrank test vs. control arm), 11 (P=0.02), and 6 days (P<0.001). Median time to ART initiation was 47, 13 (P=0.03), 15 (P=0.10), and 15 days (P=0.001). In multivariable regression models adjusted for age, gender, district of residence, education, and CD4 result, receipt of an SMS was associated with earlier return to clinic (adjusted hazard ratio [AHR] = 2.4, 95%CI 1.6 - 3.6, P<0.001) and shorter time to ART initiation (AHR=1.7, 95%CI 1.0 - 2.7, P=0.04). Among those with normal results, a greater proportion who received an SMS message returned within 7 days of their scheduled return date (81 vs 62%, P=0.001).

**Conclusions:** An SMS-based laboratory result communication system coupled with transportation incentives significantly decreased time to clinic return and time to ART initiation after abnormal CD4 test results.
CD4 T-Cell Responses in Relationship With Immune Activation and Viral Load in Primary HIV Infection

Mathieu F. Chevalier1, Céline Didier1, Gaël Petitjean1, Pierre-Marie Girard2, Françoise Barré-Sinoussi1, Daniel Scott-Algara1, Laurence Weiss3, 4

1Institut Pasteur, Paris, France, 2AP-HP, Hôpital Saint-Antoine, Paris, France, 3Université Paris Descartes, Paris, France, 4AP-HP, Hôpital Européen Georges Pompidou, Paris, France

**Background:** Early events during primary HIV infection (PHI) are thought to influence disease outcome. Although few studies have characterized HIV-specific CD4 T cells during PHI, a growing body of evidence suggests a beneficial role of functional CD4 T-cell responses in different aspects of protective immunity in HIV infection. It is unclear how viral replication and systemic immune activation may shape these responses. Here, we longitudinally investigated polyclonal and HIV-specific CD4 T-cells in relationship with the immuno-virological status of patients with PHI.

**Methodology:** 27 patients with early PHI were included in a prospective longitudinal study and followed-up for 6 months. T-cell activation, natural Tregs, Th1, Th17 and Th1/Th17 cells were assessed by cytometry on fresh PBMC. Cytokine-producing effector CD4 T cells were quantified by intracellular cytokine staining on isolated peripheral CD3+CD4+ cells stimulated with PMA/ionomycin for 5h or with the HIV-1 gag p24 antigen for 72h in the presence of autologous monocytes. Statistical significance was assessed using the Mann-Whitney or the Wilcoxon matched-paired non-parametric tests.

**Results:** Two groups of patients were segregated based on the level of CD8 T-cell activation at baseline (the groups with lower immune activation (LIA, n=13) and higher immune activation (HIA, n=14) were defined as % HLA-DR+CD38+ CD8 T cells < median and ≥ median, respectively). Following PMA/ionomycin activation, compared to patients with HIA, patients with LIA exhibited higher frequency of CD4 T cells producing IFNγ (p=0.039) or IL-17 (p=0.018). Also, patients with LIA exhibited higher effector/regulatory T-cell balance (p=0.001 when considering the Th1/Treg ratio; p=0.039 when considering the Th17/Treg ratio). No differences were found in the frequency of HIV-specific CD4 T cells between both groups. However, patients with plasma viral load (pVL) > median had higher IFNγ (p=0.031), IL-2 (p=0.018), IL17 (p=0.037) and IFNγ/IL17 (p=0.009) HIV-specific CD4 T cells compared to patients with pVL < median. Of note, the frequency of IFNγ (but not of IL-2) HIV-specific CD4 T cells significantly diminished between baseline and month 6 only in patients receiving ART during the follow-up (p=0.014).
Conclusions: Immune activation in PHI is associated with low polyclonal effector CD4 T cell responses but not related to levels of HIV-specific responses suggesting that immune activation is mainly driven by the virus and innate responses rather than by HIV-specific responses. In addition, the frequency of HIV-specific Th1, Th17 and Th1/Th17 cells is positively associated with plasma viral load, suggesting that these cells are driven by viral replication but not able to contribute to its control in the early phase of infection.

266  Herpesvirus Infections in HIV+ Individuals On ART Are Not Associated With Immune Activation

Bernard J. Macatangay1, Yue Chen1, Artemis Bullotta1, Aarika Yates2, Eric Fialkovich2, Luanz Borowski2, William Buchanan2, Phalguni Gupta2, Charles Rinaldo2
1Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, 2Infectious Disease and Microbiology, University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA, United States

Background: We assessed whether systemic reactivation of herpesviruses contributes to innate immune activation and inflammation observed in treated chronic HIV-1 infection.

Methodology: We obtained whole blood, plasma, throat washings, urine, semen, and stool specimens from HIV-1(+) MSM in the Multicenter AIDS Cohort Study (MACS) who were <50 years old, on suppressive ART for at least 2 years, and with CD4+ T cell counts >500 cells/mL (HIV+; N=15) as well as in matched, CMV IgG(+), seronegative MSM controls (NC; N=12). HSV 1 and 2, CMV, EBV, HHV6, and HHV8 DNA were measured using multiplex real time PCR. ELISA was done on plasma samples to assess levels of monocyte (sCD14) and macrophage (sCD163) innate immune activation, and soluble markers of inflammation and coagulation (IL-6, hsCRP, and D-dimer). Immunologic and virologic parameters were compared between the two groups using the Mann Whitney test, and for correlations using the Spearman rank test.

Results: 14/15 HIV+ and 11/12 NC showed evidence of herpesvirus reactivation, in a median of 2 body compartments in HIV+ compared to 1 in NC. Herpesviral DNA was detected mostly in throat washings of both groups. HHV6 was the most common virus detected in both groups (73.3% in HIV subjects and 66.7% in controls). HIV+ had reactivation in more body compartments (p=0.0371) and a trend for multiple types of herpesviruses (p=0.074), with up to 5 different herpesviruses reactivating in different body compartments during suppressive ART. CMV reactivated more in HIV+ (6/15;40%) than in NC (1/12;8.3%), and was mostly detected in semen. HIV+ had significantly higher levels of plasma sCD14 than NC (p=0.0058). However, these levels did not correlate with the number of herpesvirus DNA copies, the number of herpesvirus types reactivating, or the number of body compartments where the herpesviruses were reactivating. Similarly, there was no correlation between these virologic parameters and the levels of pro-inflammatory biomarkers, IL-6 and hsCRP. There was no significant difference in the levels of macrophage activation (sCD163) or in the levels of pro-inflammatory biomarkers. Levels of D-dimer were also similar between the two groups.

Conclusions: HIV(+) MSM who are virally suppressed on ART and with immune reconstitution (CD4>500) exhibit more systemic herpesvirus reactivation than age and risk-factor matched HIV seronegative controls. However, this viral reactivation was not associated with increased levels of innate (monocyte) activation markers that are observed in these individuals.

267  Chronic Inflammation in HIV-1 Infected Individuals Reduces T-Cell Responsiveness To Vaccines

Jean Boyer1, Lorenzo Ramirez1, Ian Frank1, Pablo Tobias1
1University of Pennsylvania, Philadelphia, PA, United States, 2Hospital of the University of Pennsylvania, Philadelphia, PA, United States

Background: Chronic inflammation remains a problem for HIV-1 infected individuals despite stable anti-retroviral therapy (ART). These low levels of inflammation, an imbalance in the cytokine/chemokine milieu, continue to exacerbate the immune deficiency of HIV+ individuals. And, therefore, these individuals may not mount an adequate immune response to vaccines, such as influenza.

Methodology: We assessed the level of inflammatory molecules in the sera of volunteers who were HIV-1 infected. We also examined cellular activation and responsiveness to HIV-1 and influenza antigens using multi-parameter flow cytometry flow cytometry and ELISPOT.

Results: We found the HIV-1 infected subjects on ART had significantly higher serum IP-10 levels as compared to healthy HIV-negative controls. Additionally, subjects showed a positive relationship between serum IP-10 levels and the percentage of activated (CD38+ HLA-DR+) central memory (CD27+ CD45RO+ CD4+ T-cells). In our in vitro studies we also found that PBMCs exposed to non-normal IP-10 levels for 24 hours demonstrated a decrease in the number of cells capable of secreting IFN-γ production when stimulated with HIV and influenza antigens. To determine the mechanism of suppression of high levels of IP-10 on the lymphocyte responsiveness we cultured PMBCs from healthy HIV-negative subjects with or without IP-10 (0.5, 10, 100ng/mL). PBMCs were either un-stimulated or stimulated with viral antigens. We again observed a decrease in IFN-γ production as well as a decrease in phosphorylation of p38 MAPK.

Conclusions: Chronic exposure to high levels of IP-10 lead to a reduction in IFN-γ production to both HIV-1 antigens as well as influenza antigens. The reduction in the T cell response to viral antigens appeared to be due a loss of p38 MAPK phosphorylation. Therefore, even with stable ART, low level chronic inflammation could lead to continued immune dysfunction, which in turn can impact responsiveness to anti-retroviral therapy, disease progression, and response to vaccination. These findings demonstrate that anti-inflammatory drugs may need to be administered to HIV-1 infected subjects on ART in order to reduce damage from low level inflammation. Such treatment could preserve and enhance T-cell immune responses to vaccination.
268  Persistently Activated CD27+CD80+ B Cells Following ART Correlate With Macrophage Activation

sCD14 vs CD27+CD80+
Spearman: r=0.54, p=0.028
Background: Antiretroviral therapy (ART) and control of HIV replication does not fully restore perturbations within resting (CD19+CD27+CD21+) and activated (CD19+CD27+CD80+) memory B cell compartments. This study was based on the hypothesis that ongoing macrophage activation and HIV-associated inflammation contributes to B cell abnormalities.

Methodology: Longitudinal cellular and soluble plasma markers for inflammation were evaluated in 43 healthy controls (HC) and 17 behaviorally-infected HIV-1+ subjects ages 18-25 years. Multicolor flow cytometry analysis of B cell subsets and assessment of markers of macrophage (sCD163 and sCD14) and lymphocyte (sCD27) were measured by ELISA. Assays were performed prior to and at 24 and 48 weeks following ART. All HIV-1 subjects suppressed HIV to < 50 copies/ml. Healthy controls and HIV+ treated subjects were also compared pair-wise and longitudinally at study entry (prior to ART), 24 weeks and 48 weeks on therapy by non-parametric rank sum.

Results: Compared to HC, resting memory B cells were lower and activated B cells were higher among HIV+ subjects at all time points before and after ART (22.6 ± 8.1% (HC) versus 16.4 ± 6.7% (HIV+ at 48 weeks) for resting memory, p=0.0081, and 11.5 ± 5.3% (HC) versus 15.2 ± 5.1% (HIV+ at 48 weeks), for activated B cells, p=0.0415, Mann-Whitney). Control of viral replication failed to decrease the proportions of activated B cells or increase memory B cells after 48 weeks on therapy. Compared to HC, sCD14, sCD27 and sCD163 all remained significantly elevated in HIV+ subjects at 48 weeks following therapy (p=0.0027, p<0.0001, and p=0.0142, respectively, Mann-Whitney). Regression analysis revealed a positive correlation between the decrease in resting memory B cells and levels of sCD14 at 48 weeks on therapy (r=0.51, p=0.038, Spearman test) but sCD163 and sCD27 did not correlate with the extent of B cell activation. Results also showed a positive correlation between the increase in activated B cells and the elevation of sCD14 24 weeks following therapy (r=0.54, p=0.028 Spearman).

Conclusions: Elevated levels of sCD14, a biomarker of macrophage activation, is the result of LPS binding to TLR4. Our results show that chronic B cell activation also reflects ongoing inflammation due to microbial translocation that may contribute to ongoing B cell dysfunction, even in HIV-infected subjects who control viral replication with ART.

269 Novel Exosomal HIV miRNAs may Contribute To Chronic Immune Activation
Mark A. Bernard
Division of Pulmonary, Critical Care and Sleep Medicine, Beth Israel Deaconess Medical Center, Boston, MA, United States

Background: Chronic immune activation may be in part attributable to translocation of microbial TLR ligands from the GI tract into the systemic circulation, but may involve direct effects of viral proteins and nucleic acids and activation of bystander host immune cells. We investigated whether novel HIV-derived miRNAs can directly induce macrophage proinflammatory cytokine release via non-canonical pathway.

Methodology: HIV miRNAs including vmiRNA-TAR and two novel HIV miRNA designated as vmiR88 and vmiR99 (determined by UNAfold RNA folding software, from R/U5 and U5 regions of HIV LTR, each with requisite short hairpin structure and highly conserved sequence vs. several clinical HIV isolates) were synthesized by IDT (Corvalis, IA). Human macrophages U937 and HIV+U1 cell lines (differentiated with PMA), and human alveolar macrophages (AM) from consenting healthy or asymptomatic HIV+ volunteers (hospital IRB-approved bronchoscopy protocol) were isolated by adherence. For select experiments, healthy AM were infected in vitro by HIV-Bal isolate x 2 weeks. For select experiments, RNAi targeted TLR8 gene silencing performed by Amaka. HIV miRNA detected by ultrasensitive qRT-PCR on cell lysates, and exosomal fraction of macrophages cultured supernatants and archived sera from healthy and asymptomatic HIV+ persons. TNF release in cultured supernatants determined by ELISA.

Results: Exosomal fraction of sera from asymptomatic HIV+ persons with CD4+ T-lymphocyte counts <200 cells/mm³, undetectable viral load, prescribed cART demonstrated abundant HIV vmiRNA-TAR in 92% of persons, in addition to both novel vmiR88 and vmiR99 each in 54% of persons, often exceeding levels of vmiR-TAR. In addition, vmiRNA-TAR, vmiR88 and vmiR99 were detected in cell lysates, released by HIV-infected macrophages upon PMA stimulation, released by AM following in vitro HIV infection, and associated with exosomal fractions. Exogenous vmiR88 and vmiR99 (but not vmiR-TAR) directly stimulated TNF release by human macrophages, dependent on macrophage TLR8 and miRNA GU-content. Finally, HIV vmiR-mediated TNF release was neutralized by specific complimentary antagonists duplexing with HIV vmiRNAs.

Conclusions: Novel HIV-derived vmiRNAs stimulate macrophage TNF release through non-canonical pathway and may contribute to chronic immune activation in HIV-infected persons. HIV miRNAs may represent novel therapeutic targets to limit HIV disease pathogenesis.

270LB Interleukin-21 Reduces Residual Immune Activation in ART-Treated SIV-Infected Rhesus Macaques
Luca Mico1, Emily Ryan1, Colleen McGarry1, Sara Paganini1, Guido Silvestri1, Jason Brenchley1, Francois Villinger1, Mirko Paiardini1
1Department of Microbiology and Immunology, Emory University, Atlanta, GA, United States, 2NIH/NIAID, Bethesda, MD, United States

Background: Current HIV antiretroviral therapy (ART) successfully inhibits virus replication, improves health, and prolongs life expectancy in people living with HIV. Although HIV replication is suppressed, residual immune activation persists and critically contributes to non-AIDS-related morbidity and mortality in ART-treated individuals. Interleukin (IL)-21 regulates three immunological functions - Th17 cell homeostasis, differentiation of memory B cells, and long-term maintenance of functional CD8+ T cells - that are compromised following HIV infection. Previously, we showed that when administered during acute infection, Interleukin (IL)-21 reduces microbial translocation and systemic immune activation in SIV-infected rhesus macaques (RMs). In this new study we investigated if administration of IL-21 to chronically SIV-infected, ART-treated RMs is effective in limiting the extent of on-ART residual immune activation.

Methodology: Sixteen RMs were infected with SIVmac239 i.v. and, starting at day 60 post-infection, were treated for seven months with PMPA, FTC, Raltegravir, Darunavir and Ritonavir. Eight RMs received IL-21-Fc (100 μg/kg, s.c., weekly for six weeks) at the beginning and at the end of ART, with the other eight serving as ART-treated controls. Longitudinal collections of blood, lymph nodes and rectum were performed. IL-21 effects on immune activation, T cell subset levels and functions were assessed by flow cytometry. The Mann–Whitney test was used for statistical analyses.
**271 Immune Activation and Risk of HIV-1 Transmission Among Discordant Couples**

**Erlin M. Kahle**, Michael Bolton, James Hughes, Deborah Donnelly, Connie Celnik, Jairam Lingappa, Allan Ronald, Guy de Bruyn, Julie McElrath, Jared M. Baeten

1University of Washington, Seattle, WA, United States; 2Fred Hutchinson Cancer Research Center, Seattle, WA, United States; 3University of Makerere, Kampala, Uganda; 4University of Witwatersrand, Johannesburg, South Africa

**Background:** Immune activation is a hallmark of chronic HIV-1 infection. A heightened pro-inflammatory state has been hypothesized to enhance HIV-1 transmission - both susceptibility of HIV-1-exposed persons and infectiousness of HIV-1-infected persons.

**Methodology:** Using data collected prospectively from heterosexual HIV-1 serodiscordant couples from 6 countries in eastern and southern Africa, we conducted a nested case-control analysis to assess the relationship between immune activation and risk of HIV-1 acquisition and transmission. Cases (N=120) included incident HIV-1 transmissions; controls (N=321) were couples in which HIV-1 transmission did not occur. Immune activation was measured in both HIV-1 susceptible and infected partners by a panel of 30 cytokines.

**Results:** For both HIV-1 infected and susceptible partners, cases and controls had significantly different mean responses in cytokine panels (Hotelling T2 p<0.001), suggesting a broadly different pattern of immune activation for couples with HIV-1 transmission events compared to those who did not transmit HIV-1. When considering elevations in specific cytokines, log10 mean concentrations were found to be significantly higher for HIV-1 susceptible cases when compared to controls for IL-10 (p=0.001) and IP-10 (p=0.002). Similarly, for HIV-1 infected partner cases and controls, log10 mean concentrations were significantly higher for IL-10 (p<0.001) and IP-10 (p<0.002). In multivariate analysis, HIV-1 transmission was significantly associated with elevated IP-10 concentrations in HIV-1 susceptible partners (p=0.001) and elevated IL-10 concentrations in HIV-1 infected partners (p=0.02).

**Conclusions:** Immune activation - particularly elevated levels of IL-10 and IP-10 - are associated with both increased HIV-1 susceptibility and infectiousness.

**272 Inflammation in Acute HIV Infection Correlates With Blood and Gut CD4 T-Cell Loss and Viral Burden**

1Internal Medicine, University of Texas Medical Branch at Galveston, Galveston, TX, United States; 2SEARCH, The Thai Red Cross AIDS Research Center, Bangkok, Thailand; 3HIV-NAT, The Thai Red Cross AIDS Research Center, Bangkok, Thailand; 4AIDS Monitoring Laboratory, Leidos Biomedical Research, Inc., Frederick, MD, United States; 5Armed Forces Research Institute of Medical Sciences – US Component, Bangkok, Thailand; 6NIADDK Vaccine Research Center, National Institutes of Health, Bethesda, MD, United States; 7NIADDK Vaccine and Gene Therapy Institute Florida, Port St. Lucie, FL, United States; 8Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States; 9NIADDK, National Institutes of Health, Bethesda, MD, United States

**Background:** Biomarkers of inflammation, coagulation and fibrosis are associated with morbidity and mortality in HIV infected persons. Understanding the changes in these biomarkers during sequential stages of acute HIV infection (AHI) before seroconversion could illuminate the course of early HIV pathogenesis.

**Methodology:** Plasma levels of D-dimer, hyaluronic acid (HA), C-reactive protein (CRP), soluble CD14 (sCD14), IL-6 and TNFα were measured from 78 AHI and 109 HIV uninfected (HIV-) Thai participants by ELFA (D-Dimer) and ELISA methods, respectively. 42 AHI participants had sigmoid biopsies. Cell-associated HIV DNA and RNA in peripheral blood and sigmoid colon were measured by PCR and RT-PCR. Subjects were divided by 4thG staging: 1 (4th generation (G) EIA-; 3rdG EIA-), 2 (4thG +; 3rdG -) and 3 (4thG +; 3rdG +, Western blot - or indeterminate). Median values were compared between groups by non-parametric methods and Spearman correlations were used for associations between variables.

**Results:** The median age in AHI versus control subjects was 28 vs. 27 years. Median time since HIV exposure was 12, 16 and 18 days in stages 1, 2 and 3, respectively. The table illustrates key data. Plasma levels of biomarkers of inflammation, microbial translocation (MT), fibrosis and coagulation correlated positively with plasma HIV viremia: TNFα (r=0.62, P<0.001), sCD14 (r=0.25, P=0.03), HA (r=0.28, P=0.01) and D-dimer (r=0.33, P=0.003) and with sigmoid HIV DNA levels: TNFα (r=0.66, P=0.002) and CRP (r=0.44, P=0.02). Increased inflammation and MT correlated with low circulating CD4 T cell counts: TNFα (r=-0.31, P=0.04) and CRP (r=-0.25, P=0.03), and low sigmoid CD4 T cell numbers: TNFα (r=-0.40, P=0.03), CRP (r=-0.31, P=0.05), sCD14 (r=-0.42, P=0.005) and IL-6 (r=-0.37, P=0.05). High HA levels (r=-0.42, P=0.006), reflecting fibrosis, correlated with low sigmoid CD4 T cell numbers. Subjects with detectable peripheral blood integrated HIV DNA at week 24 had higher baseline TNFα (8.9 vs. 6.4 pg/mL, P=0.02), sCD14 (2.2 vs. 1.3 μg/mL, P=0.01) and D-dimer (0.41 vs. 0.24 μg/mL, P=0.01) levels.

**Conclusions:** Biomarkers of inflammation, coagulation and fibrosis are elevated in AHI before seroconversion. The temporal course of these biomarkers suggests that peak viral burden and inflammation trigger a pro-thrombotic and pro-fibrotic response. Stage 2 may represent the peak of immunologic destruction and thus a critical point for early intervention to prevent further immune decay and ultimately HIV disease.

NK Cells in HIV Pathogenesis

273  NK Cell Subsets Responding To HIV-Infected Autologous CD4 T Cell in Protective KIR/HLA Genotypes

Irene Lisovsky1,2, Rujun Song2, Bertrand Lebouché1, Jean-Pierre Routy1, Julie Brunneau, Nicole F. Bernard1, 2

1Division of Experimental Medicine, McGill University, Montreal, QC, Canada, 2Research Institute of the McGill University Health Centre, Montreal, QC, Canada, 3Medicine Division of Experimental Medicine, McGill University, Montreal, QC, Canada, 4Chronic Viral Infection Service, McGill University Health Centre, Montreal, QC, Canada, 5Division of Hematology, Royal Victoria Hospital, McGill University Health Centre, Montreal, QC, Canada, 6Centre de Recherche du Centre Hospitalier de l’Université de Montréal (CRCHUM), Montreal, QC, Canada, 7Division of Experimental Medicine, McGill University, Montreal, QC, Canada

**Background:** Genetic and epidemiological studies implicate NK cells in HIV resistance and slow disease progression in infected individuals. This protective effect is achieved by interactions between NK cell surface receptors called KIRs and their ligands, HLA molecules. These interactions are important for NK cells to gain functional potential during a developmental process known as education. The receptor KIR3DL1 with its ligand HLA-B*57 (*h/*y+B*57) has the strongest effect on slow time to AIDS and HIV viral load control compared to Bw6 homozygotes (Bw6hmz). *h/*y+B*57 carriers have a stronger effect on these outcomes than do carriers of *l/*x+B*57. Levels of KIR3DL1 on NK cells from *h/*y+x+B*57 carriers are lower than those from *l/*x+B*57 carriers. NK cells from *h/*y+B*57 carriers receive potent educational signals through HLA-B*57 KIR3DL1 ligation leading to high functional potential. Since Bw6 antigens do not interact with KIR3DL1, NK cells from Bw6hmz are not educated through KIR3DL1. Here we investigated whether KIR/HLA genotype influences the potency of NK-mediated inhibition of viral replication and NK cell subset responses to autologous HIV-infected CD4 cells.

**Methodology:** The study population included carriers of *h/*y+B*57 (n=7), 3DS1+*80I (n=9), *l/*x+B*57 (n=4) and Bw6hmz (n=11). We measured NK cell mediated inhibition of HIV replication in autologous infected CD4 T cells by assessing the supernatant levels of HIV p24 longitudinally. We measured CC-chemokine secretion following stimulation with autologous infected CD4 cells by ELISA and multi-parametric flow cytometry.

**Results:** NK cells from *h/*y+B*57 carriers inhibited HIV replication in autologous infected CD4 T cells as well as those from 3DS1+*80I carriers (p>0.05) and better than those from Bw6hmz and *l/*x+B*57 positive subjects (p<0.05 for all comparisons Mann-Whitney test). Infected CD4 cells stimulated NK cells from *h/*y+B*57 and 3DS1+*80I carriers to produce higher levels of CC-chemokines than those from Bw6hmz (p<0.05). Intracellular cytokine staining of stimulated NK cells and NK subsets confirmed that NK cells were the source of CC-chemokines. A higher frequency of NK cells from carriers of *h/*y+B*57 than Bw6hmz secreted these CC-chemokines and in *h/*y+B*57 carriers more KIR3DL1+ than KIR3DL1- secreted these chemokines.

**Conclusions:** NK cells from carriers of *h/*y+B*57 inhibit HIV replication in autologous CD4 T cells more effectively than those from *l/*x+B*57 carriers and Bw6hmz. This suggests that NK cell education influences the potency of NK cell mediated inhibition of HIV replication. The inhibition of viral replication in autologous infected CD4 T cells involves responses by KIR3DL1 subset and is partially due to secretion of CC-chemokines.
274 Siglec-7 Binds HIV-1 GP120 and Facilitates Infection of CD4pos T Cells and Macrophages
Stefania Varchetta1, Paolo Lusso1, Dalia Mele1, Stefania Paolucci1, Raffaello Cimbro2, Mauro Malnati1, Agostino Riva1, Renato Maserati1, Mario U. Mondelli1, Domenico Mavilio1
1Department of Infectious Diseases, Fondazione IRCCS Policlinico, Pavia, Italy, 2Laboratory of Immunoregulation, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, 3Unit of Human Virology, San Raffaele Scientific Institute, Milan, Italy, 4Dipartimento di Scienze Cliniche (DISC), Luigi Sacco Hospital and University of Milan, Milan, Italy, 5Department of Medical Biotechnologies and Translational Medicine, Humanitas Research Center and University of Milan, Rozzano (Milan), Italy

Background: Sialic acid-binding Ig-like lectin-7 (Siglec-7) expression is strongly reduced on natural killer (NK) cells from HIV-1 infected viremic patients. To investigate the mechanism(s) underlying this phenomenon, we hypothesized that Siglec-7 could directly interact with the HIV-1 envelope (Env) glycoprotein (gp120), thus contributing to the infection of target cells.

Methodology: The binding of Siglec-7 fusion protein to HIV-1 GP 120 was detected by flow cytometry by using a protein-bead conjugation technology. The Siglec-7-induced rates of infection of CD4+ T cells and monocytes-derived macrophages (MDMs) were assessed by detecting HIV-Env in cell supernatants and by HIV-1 entry assay. The amounts of soluble Siglec-7 (sSiglec-7) in HIV-infected patients' sera were measured by ELISA.

Results: We found that Siglec-7 binds gp120 Env in a sialic acid-dependent manner. Pre-incubation of HIV-1 with sSiglec-7 increases the infection rate of CD4+ T cells, which do not constitutively express Siglec-7. Conversely, selective blockade of Siglec-7 markedly reduces the degree of HIV-1 infection in Siglec-7+ MDMs. Finally, the amount of sSiglec-7 is increased in the serum of AIDS patients compared to that of healthy donors and inversely correlates with CD4+ T cell counts.

Conclusions: Our results show that Siglec-7 binds HIV-1 and contributes to enhance the degree of infection of CD4+ T cells and MDMs. Indeed, our study demonstrates that Siglec-7 increases HIV-1 viral entry in CD4+/Siglec-7- T cells in its soluble form while it reduces infection in CD4+/Siglec-7+ MDMs if masked/blocked on cell surface. Together with our previous data showing a pathologic expansion of highly dysfunctional CD56-/Siglec-7- NK cells in AIDS patients also carrying higher levels of sSiglec-7 in their sera, our findings provide evidence that this lectin-type molecule plays an important role in HIV-1 pathogenesis by being associated with an higher susceptibility of CD4+ target cells to be infected by HIV-1 and with disease progression. The disclosure of these novel insights suggest that Siglec-7 might serve as potential biomarker to monitor the clinical course of HIV-1 infection and can also represent a therapeutic target to inhibit viral replication/spreading thus limiting the depletion of CD4+ T cells.

275 Monocyte and NK Cell Dysfunctional Responses To Mycobacteria During Chronic HIV-1 Infection
Melanie A. Gasper1,4, David R. Sherman1, Donald L. Sodora1
1Seattle Biomedical Research Institute, Seattle, WA, United States, 2Pathobiology Graduate Program, University of Washington, Seattle, WA, United States

Background: Coinfection with M. tuberculosis (Mt) and other Mycobacteria is a leading cause of morbidity and mortality in HIV+ patients. While neither monocytes nor NK cells are directly infected with HIV, several of their phenotypic and functional properties become altered during chronic infection, and both cell types are important to the control of Mt. We hypothesized that HIV-related NK cell dysfunction may result from impaired monocyte dysfunction and impaired crosstalk with NK cells, which we will evaluate in the context of Mycobacteria infection.

Methodology: To assess monocyte cytokine production, whole blood from HIV+ ART-naïve patients and healthy donors was stimulated with Mycobacteria for 6 hours (in the presence of Brefeldin-A) and followed by intracellular cytokine staining. For cellular functional assays, cells were isolated from PBMC and impaired phagocytosis. Autologous NK cells were utilized to assess cell killing.

Results: We observed a decrease in IL-12 (p=0.017), but similar TNF-alpha production, by blood monocytes from HIV+ individuals following a 6 hour stimulation with M. Bovis BCG (opportunist pathogen), compared to uninfected donors. As IL-12 is known to regulate NK cell functionality, we were also interested in evaluating NK cell function in our cohort. While developing a flow-based functional assay to measure NK cell killing of autologous Mt-infected monocytes, we found that NK cells from HIV+ donors exhibited decreased killing of target K562 cells compared to controls (p=0.04). Further evaluation established that monocytes from the same HIV+ patients in which we identified lower NK cell killing also exhibited decreased phagocytosis of fluorescently-labeled BCG (p=0.016) but similar phagocytosis of Mt compared to uninfected donors.

Conclusions: Our data demonstrate a reduction in both monocyte and NK cell functionality in the same HIV-infected patients and is suggestive of synergism in the dysfunction of two innate cell types in our patients. The assays described have the potential to identify novel therapeutic targets to enhance innate (both monocyte and NK cell) cellular function in HIV-infected patients.

276 Identification of a New Isoform of MLL5: A Surrogate Marker of the CD4 Depletion in HIV-1
Vincent Vieillard1, Florence Baychelier1, Alexis Sennepin1, Myriam Ermonval2, Karim Dorgham1, Patrice Debre1
1INSERM UMR-S 945, Paris, France, 2Département de Virologie, Institut Pasteur, Paris, France

Background: Nkp44 is a unique member of the natural cytotoxicity receptor family, which is exclusively expressed on activated NK cells. We had previously shown that the cellular ligand of Nkp44, called Nkp44L, is specifically expressed on bystander non-infected CD4+ T cells during HIV infection. Thus, over the ensuring years, we showed that Nkp44L expression is induced by a remarkably conserved motif of the HIV-1 gp41, and correlated to CD4 depletion, T cell activation, inflammation and apoptosis. To better understand the relations between Nkp44 and the HIV-pathophysiology, we undertook studies to identify and characterize its cellular ligand, Nkp44L. We report here that Nkp44L is a new isoform of the mixed-lineage leukemia-5 (MLL5) gene.

Methodology: Nkp44L has been cloned using the yeast 2-hybrid system, and then confirmed by immunoprecipitation with anti-MLL5 or anti-Nkp44L Abs followed by immunoblotting with Nkp44L fusion protein. Expression of Nkp44L was tested by Northern blot, immunofluorescence and flow-cytometry. Functional assays were performed using a standard 51Cr release assay.
Do KIR3DL1/HLA-B Combinations Influence ADCC Responses of HIV-1 Infected Slow Progressors?

Ganze Isitman1,2, Zoya Padamsi1,2, Pilar Zanoni1,2, Matthew Parsons1, Marianne Harris1, Jean-Pierre Routy1,2, Cecile L. Tremblay1, Nicole F. Bernard1,2

1Division of Experimental Medicine, McGill University, Montreal, QC, Canada, 2Research Institute of the McGill University Health Centre (RI-MUHC), Montreal, QC, Canada

Background: The *h*/γ+y+B*57 genotype, which encodes high expression Killer Immunoglobulin-like Receptor (KIR)3DL1 variants and HLA-B*57 is the KIR/HLA combination with the strongest effect on slowing time to AIDS and controlling HIV viral load, as compared to Bw6 homozygotes (Bw6hmz). The interaction of 3DL1 with HLA-B*57 is a potent natural killer (NK) cell licensing combination. NK cell licensing plays a role in the potency of antibody dependent cellular cytolysis (ADCC) activity.

The percentage of functional NK cells induced by HLA-null or autologous HIV-infected CD4 cells is higher when from *h*/γ+y+B*57 carriers than from Bw6hmz or carriers of several other 3DL1hmz/HLA-Bw4 combinations. Using cells from HIV-infected slow progressors (SP) we investigated whether KIR3DL1/HLA genotypes that support licensing (3DL1+Bw4) generate NK cells with higher ADCC activity than that do not (3DL1+Bw6hmz). Our hypothesis is that NK cells from HIV-infected SP mediate ADCC activity.

Methodology: We studied 48 3DL1hmz SP with plasma viral loads <3000 cells/mm3, including HLA-Bw4+ HLA-B*57- (n=34), HLA-Bw6hmz (n=12) and *h*/γ+y+B*57 (n=6) carriers. Anti-HIV ADCC was measured using a GranToxiLux (GTL) assay, which assesses the ability of NK cells (effectors) to deliver granzyme B (GzB) to HIV gp120-coated CEM.Nkr.CCR5 targets (%GzB+ cells) in the presence of a common pooled source of anti-HIV immunoglobulin G.

The significance of between group differences was assessed using the Mann-Whitney test.

Results: NK cells from all HLA-Bw4+ and Bw6hmz 3DL1hmz mediated equivalent levels of ADCC (21.1 ± 13.9 vs 24.05 ± 20.7 %GzB cells+, p=0.87). NK cells from *h*/γ+y+B*57 carriers also mediated the similar levels of ADCC activity (20.7 ± 16.1) as those from Bw6hmz (p=0.96) and carriers of other Bw4 alleles (21.1 ± 13.8, p=0.85).

Conclusions: NK cells from HIV infected SP mediate ADCC. Carrying KIR/HLA combinations, that play a role in NK cell licensing through KIR3DL1 ligation, does not influence the potency of ADCC activity of NK cells from HIV-infected SP. These results contrast with previous studies by us and others using NK cells from uninfected individuals, where KIR3DL1/HLA-B genotype does appear to influence levels of ADCC activity. Further investigation will be needed to determine whether HIV infection even in this well controlled SP population abrogates the influence of licensing on NK mediated ADCC activity.

CD8+ NK Cells in HIV-1 Infection Are Associated With Slower Disease Progression Towards AIDS

Fareed Ahmad1, Hencho S. Hong1,2, I-Na Lu1, Marc Jäckel1, Nupur Bhatnagar1, Johanna M. Eberhardt1, Benjamin A. Bollmann1, Reinhold E. Schmidt1, Dirk Meyer-Olson1,4

1Clinic for Immunology and Rheumatology, Hannover Biomedical Research School (HBRS), Medizinische Hochschule Hannover (MHUH), Hannover, Germany, 2Division of Immunology, Hanard Medical School, Southborough, MA, United States, 3Clinic for Immunology and Rheumatology, Medizinische Hochschule Hannover (MHUH), Hannover, Germany, 4Rheumatologie, KVG Klinik in Bad Pyrmont Verwaltungs GmbH & Co Betriebs KG, Bad Pyrmont, Germany

Background: NK cells are part of the innate immune system and provide one of the first lines of immune defense and its regulation. Although increasing evidence suggests a protective role of NK cells in HIV-1 infection the phenotypical and functional NK cell parameters correlating with a slower disease progression are currently poorly understood.

Methodology: A cohort of 117 untreated chronic HIV-1 infected subjects with CD4+ helper cell counts above >500/μl were longitudinally followed at our institution. We analyzed NK cells from 53 untreated, 25 treated HIV-patients and 15 healthy controls with flow cytometry. Analysis of the degranulation marker CD107a and cytokine production (IFN-γ, TNF-α, MIP-1β) were assessed after stimulation with IL-12, IL-15 and K562 cells. Statistical analyses included unpaired t test, One-way ANOVA followed by Tukey post test when comparing more than two groups, Kaplan Meier and Pearson analysis to identify correlations.

Results: High NK cell as well as CD8+/CD3- lymphocyte counts were associated with slower disease progression in a longitudinal analysis of untreated patients. In addition, we found a robust inverse correlation between frequencies of CD8+ NK cells with HIV viral loads and direct correlation with CD4+T cell counts as well as CD4/CD8 ratio. In a cross-sectional analysis we observed substantially reduced numbers of CD8+ NK cells in HIV-1 seropositive patients compared to healthy controls, which were partially restored after initiation of antiretroviral therapy. There were no significant phenotypic differences between CD8+ and CD8- NK cells for a number of markers, except for the CD57, which was higher among CD8+ NK cells. Further analysis of CD8+ NK cells revealed higher frequencies of granzyme B and perforin-expressing cells among CD8+ NK cells compared to CD8- NK cells. Degranulation capacity,
secretion of IFN-γ, TNF-α, and MIP-1β were higher amongst CD8+ NK cells. Importantly, the frequency of polyfunctional CD8+ NK cells were higher in HIV-infected individuals with viral loads below 10,000 copies/ml compared to HIV-seronegative individuals. Notably, the lowest frequency of polyfunctional CD8+ NK cells was observed in HIV-infected individuals with viral loads above 10,000 copies/ml suggesting that viremia impacts the functionality of CD8+ NK cells.

Conclusions: We identified the frequency of highly functional CD8+ NK cells as a parameter for delayed disease progression towards AIDS in untreated HIV-1 infected patients. It is thus tempting to speculate that CD8+ NK cells can play a prominent protective role in HIV infection.

279 HLA-B*35:05 Is a Protective Allele With a Unique Structure Amongst CRF01_AE-Infected Thais
Masahiko Mori1,2, Nuanjun Wichulchinda3, Reiko Miyahara1, Archawin Rojanawiwat1, Panita Pathipvanich4, Tomoyuki Maekawa5, Philip Goulder2, Michio Yasunami1, Koya Arizohi1, Pathom Sawanpanyalert6
1Department of Clinical Medicine, Nagasaki University, Institute of Tropical Medicine, Nagasaki, Japan, 2Department of Paediatrics, University of Oxford, Oxford, United Kingdom, 3Department of Medical Sciences, Ministry of Public Health, Nonthaburi, Thailand, 4Day Care Centre, Lampang Hospital, Lampang, Thailand

Background: About 1,500 of CTL epitopes including 250 best-defined epitopes and their restricting HLA allele data have accumulated in the Los Alamos database. However, most of these have been derived from subtype-B-infected Caucasians, and from subtype C-infected Africans. Studies from south-east Asia, where about 1.5 million patients are living with HIV, and where about 90% of them are infected with subtype CRF01_AE, remain sparse. Although HLA-B*57 is a protective allele amongst Africans and Caucasians, its prevalence amongst Asians is lower than other ethnic groups.

Methodology: 1) S57 HIV-1 CRF01_AE-infected Thais were recruited, and their HLA type and viral load were determined to statistically analyze the association of each allele in viral control. 2) In silico molecular dynamics was used to evaluate the effect of HLA structure variants on epitope binding. 3) Recently HLA-B*35-restricted epitope Gag 253-262 NNPPIPVGDIY, which D260E escape mutation causing HLA-epitope binding instability and consequent viral load increase, was reported. Sequence mutation at this site was statistically analyzed amongst HLA-B*35:05 positives and HLA-B*35:01 positives.

Results: HLA-B*35:05 was identified as the most protective allele (p=0.003, q=0.17), along with HLA-B*57:01 (p=0.044, q=0.31). Structurally HLA-B*35:05 belongs to PY, which has epitope binding motif of Pro (P) at HLA B pocket and Tyr (Y) at F pocket. However, unlike other HLA-B*35 alleles with Arg (R) at HLA residue 97, HLA-B*35:05 has unique sequences at Thr (T) at 94, Leu (L) at 95, and Ser (S) at 97, located at the peptide-binding groove. Analysis of 3D HLA structure and molecular dynamics showed that S97 in HLA-B*35:05 led to 1) less flexibility in the groove, and 2) shorter distances between the α-helices compared to the other PY, HLA-B*35:01, suggesting fewer peptide variants will be able to bind to the groove, leading to induction of stronger virus-specific immunity by HLA-B*35:05. In the viral sequence at Gag 253-262 NY10, mutations were significantly identified amongst HLA-B*35:01 positives; p=0.0001 by Fisher’s exact test at D260E, p=0.0025 at I261X, and p=0.019 at flanking N252X. However, there was no significant mutations amongst HLA-B*35:05 positives in this site.

Conclusions: Our data indicates the existence of a protective effect of HLA-B*57 across ethnic groups and highlights HLA-B*35:05 as an allele uniquely protective in subtype CRF01_AE-infected Thais, due to its divergence from conventional PY structural sequences at the peptide-binding groove. Identification of unique protective alleles in all endemic area provides the opportunity to better define the nature of HLA-mediated immune control and will be valuable for CTL vaccine development.

280 Eomes and T-Bet Are Differentially Linked To CD8+ T-Cell Exhaustion in HIV Infection
Johanna Tauriainen1, Marcus Bugger1, Takuya Yamamoto2, Bo Hejde1, Richard A. Koup3, Marianne Jansson4, Anders Sonnerborg5, Michael R. Betts6, Annika C. Karlsson7
1Department of Laboratory Medicine, Institute of Clinical Microbiology, Karolinska Institutet, Stockholm, Sweden, 2Immunochemistry Laboratory, Vaccine Research Center, National Institutes of Health, Bethesda, MD, United States, 3Stockholm South General Hospital, Stockholm, Sweden, 4Department of Immunology, Karolinska Institutet, Stockholm, Sweden, 5Department of Microbiology, Tumor and Cell Biology (MTC), Karolinska Institutet, Stockholm, Sweden, 6Department of Microbiology, University of Pennsylvania, Philadelphia, PA, United States

Background: Loss of CD8+ T cell functionality (exhaustion) represents a major hallmark of chronic HIV infection. T cell exhaustion is generally considered as a consequence of several factors that drive T cells to senescence. However, a mechanistic explanation between the transcriptional regulation of CD8+ T cell differentiation and exhaustion remains elusive. Here we conducted a comprehensive multi-parametric study to elucidate whether two T-box transcription factors governing cytolytic T cell differentiation, T-bet and Eomesodermin (Eomes), were linked to exhaustion of human viral-specific CD8+ T cells.

Methodology: In this prospective study, 52 untreated chronically HIV infected individuals and 20 healthy controls were recruited from the HIV clinics at Karolinska University Hospital Huddinge and Stockholm South General Hospital. A total of 24 patients initiated ART and were followed longitudinally for 6 months. Peripheral blood mononuclear cells were collected and flow cytometry was used to assess immunological markers. The samples were acquired on an LSR Fortessa and data analysis was performed in FlowJo. Non-parametrical tests were performed using GraphPad Prism and SPICE.

Results: We provide evidence that an inverted relationship between T-bet and Eomes is closely linked to exhaustion of human memory and viral-specific CD8+ T cells. Single and co-expression of inhibitory receptors (PD-1, CD160 and 2B4) was thoroughly related to a transcriptional profile of EomesiT-betdim memory CD8+ T cells. HIV infected subjects showed increased expression levels of PD-1, CD160 and 2B4 compared to healthy controls, which was closely linked to elevated expression of Eomes. Consistently, HIV-specific T cells were trapped within this transcriptional profile (EomesiT-betdim),
while the anti-CMV CD8+ T cell response displayed a balanced expression pattern between T-bet and Eomes. Highly exhausted cells did not show any features of terminal differentiation, but rather a transitional memory phenotype with poor functional abilities for both HIV- and CMV-specific CD8+ T cells. Interestingly, a decay of the MFI of PD-1 and Eomes was related to each other longitudinally in HIV infected individuals initiating ART. However, in most individuals initiating ART, the HIV-specific CD8+ T cell repertoire still retained elevated frequencies of PD-1, CD160, 2B4 as well as Eomes, and lower T-bet expression.

**Conclusions:** The current data implicate that CD8+ T cell exhaustion is influenced by differential expression of T-bet and Eomes. This study supports the concept that poor viral-specific T cell functionality is not due to senescence, but rather an intermediate transcriptional profile that impedes the clearance or control of specific human chronic viral infections.

### 281 Increased Frequencies of HLA-G+ HIV-1-Specific Regulatory CD8 T Cells in HIV-1 Controllers

**Selena Viganò**, Chun Li, Jordi Negroni, Florencia Pereyra, Matthias Lichterfeld, Xu Yu

**Background:** Regulatory T cells may influence HIV-1 disease progression by suppressing immune activation or inhibiting antiviral T cell immune responses. Recent data suggest that the proportion of non-classical regulatory CD4 and CD8 T cells expressing HLA-G was inversely correlated with markers of HIV-1 associated immune activation, as opposed to non-classical regulatory T cells expressing the TGF-b latency-associated peptide (LAP). The role of non-classical regulatory T cell specific for HIV-1 is unknown.

**Methodology:** 31 HIV-1-specific and 19 CMV/EBV specific CD8 T cell responses were analyzed in 31 HIV-1 infected patients. 17 patients were chronic progressors with median HIV viral load 42500 copies/ml and median CD4 T cells count 456/μl. 14 patients were controllers with viremia below 1000 copies/ml and CD4 T cell counts above 900/μl. HLA-G and LAP expression on HIV-1 specific CD8 T cells was assessed by multimer staining and flow cytometry.

**Results:** The frequency of HLA-G+ HIV-1 specific (p=0.015), but not CMV- or EBV-specific (p=n.s) CD8 T cells was increased in controllers when compared to chronic progressors. This increase was mostly driven by HLA-G+ CD8 T cells restricted by protective HLA class I alleles (p=0.05), while no difference between controllers and chronic progressors was observed when CD8 T cells restricted by non-protective alleles were selectively analyzed. The proportion of HLA-G+ HIV-1-specific CD8 T cells was directly associated with CD4 T cell counts (p=0.0003, r=0.48), but not with viral loads. In contrast, LAP+ HIV-1-specific CD8 T cells were reduced in frequency in controllers in comparison to chronic progressors and their frequency was directly associated with viral loads (p=0.0006, r=0.61) and inversely associated with CD4 T cell counts (p=0.024, r=-0.4).

**Conclusions:** These data indicate a potentially protective role of HIV-specific HLA-G+ regulatory CD8 T cells on HIV-1 disease progression. Further investigations of functional properties of these antigen-specific, non-classical regulatory CD8 T cells are necessary in order to better elucidate their role in HIV immunopathogenesis.

### 282 CD8+CD28-CD127loCD39+ Treg: A New Biomarker for HIV Infection

**Chiara Dentone**, Daniela Fenoglio, Alessia Parodi, Francesca Kalli, Antonio Di Biagio, Paolo Fraccaro, Giancarlo Orofino, Giovanni Cenderello, Mauro Giacomini

**Background:** The phenotype of non-antigen specific CD8+ T regulatory lymphocytes (Treg) has been recently characterized as CD8+CD28-CD127loCD39+. In order to study the in vivo compartmentalization of this newly recognized Treg subset, we analyzed its frequency in the peripheral blood of patients (pts) affected by cancer and HIV infection, characterized by an abnormal expansion of regulatory circuits and immunodeficiency, in comparison with healthy subjects (HS).

**Methodology:** We analyzed these cells with FACSCanto II flow cytometer in HS, in pts affected with cancer and in HIV infected pts subdivided in elite controllers (EC) with CD4+T cells ≥ 400/mm³ and persistent HIVRNA ≤ 50 cp/ml without antiretroviral therapy (ART); long term non progressor (LTNP) with CD4+ T cells ≥400/mm³ and HIVRNA > 50 and < 1000 cp/ml without ART and progressor (HIVRNA ≤ 50 copies/ml treated with at least 2 ART regimens). Statistically significant differences between frequencies were assessed using the Fisher’s exact test for binary variables, while statistically significant differences between means were analyzed with the Mann-Whitney test for non-parametric values.

**Results:** We included 24 HS, 34 pts with cancer subdivided in elite controllers (EC) with CD4+T cells ≥400/mm³ and persistent HIVRNA ≤ 50 cp/ml without antiretroviral therapy (ART); 8 EC, 5 LTNP and 20 progressor The CD8+CD28-CD127loCD39+ T reg were detected in 1/24 (4%) of HS and the frequency was very low (0.1%). The analysis of the frequency of CD8+CD28-CD127loCD39+ Treg in the surgical tumor specimens showed that these cells were present in 30 out of 34 (88%) total tumors with comparable frequencies between renal and bladder cancers. While these cells were rare in EC and LTNP (2/13 patients [15%]), they were present with high frequency in 95% of progressors (p=0.0001).

**Conclusions:** These data show the existence of a T cell subpopulation, CD8+CD28-CD127loCD39+ Treg, that is substantially unrepresented in the circulation of healthy subjects, but that circulates in the peripheral blood of cancer or HIV-infected patients. This finding configures CD8+CD28-CD127loCD39+ Treg as an optimal biomarker for diagnostic/prognostic or follow-up purposes in diseases characterized by an abnormal predominance of regulatory circuits, as cancer and HIV infection.
Determination of PD-1 Expression On CD4+ and CD8+ T Cells in Treated and Untreated HIV Disease

Leslie R. Cockerham1, Vivek Jain1, Elizabeth Sinclair2, David V. Glidden3, Wendy Hartogenesis4, Hiroyu Hatano1, Peter W. Hunt1, Jeffery N. Martin1, Frederick M. Hecht1, Steven G. Deeks3

1HIV/AIDS Division, University of California - San Francisco, San Francisco, CA, United States, 2Division of Experimental Medicine, University of California - San Francisco, San Francisco, CA, United States, 3Department of Epidemiology and Biostatistics, University of California - San Francisco, San Francisco, CA, United States, 4St. Jude Children's Research Hospital, Memphis, TN, United States

Background: Expression of programmed death 1 (PD-1) is upregulated on CD4+ and CD8+ T cells in untreated HIV infection, resulting in decreased proliferation and function. The impact of antiretroviral treatment (ART) and the determinants of PD-1 expression in CD4+ and CD8+ T cells are not fully understood.

Methodology: We assessed T cell expression of PD-1 longitudinally in a cohort of acutely infected HIV+ individuals who started ART early (6 months) vs. late (2 years after infection) and cross-sectionally in a diverse cohort of chronically HIV-infected adults, including elite controllers and long-term immunologic non-responders (INRs; individuals who failed to achieve a CD4+ T cell count >500 cells/mm3 on long-term ART). PD-1 MFI was measured by flow cytometry on total CD4+ and CD8+ T cells and T cell subsets. Longitudinal mixed effects regression modeling was done to assess the impact of ART and other factors on PD-1 expression.

Results: In the longitudinal cohort (n=121), PD-1 expression increased an average of 6.4% and 7.9% each year without ART on CD4+ and CD8+ T cells, respectively. Early ART initiation resulted in a rapid decline in PD-1 expression on CD8+ T cells (41% after one year of ART, P < 0.001); similar results were observed in CD4+ T cells. Delayed ART resulted in a similar decline in PD-1 expression. In the cross-sectional cohort (n=206), PD-1 expression remained high in INRs (median MFI of 218 vs. 130 in responders vs. NRs, P < 0.001). This effect was seen in all T cell memory subsets. Compared to HIV-uninfected, elite controllers had similar PD-1 expression on both total CD4+ and CD8+ T cells, while viremic controllers had higher PD-1 on effector memory CD8+ T cells (P = 0.03). Amongst all ART suppressed subjects in both cohorts, PD-1 expression on CD4+ T cells was strongly associated with CD4+ T cell activation (ρ = 0.53, P < 0.001) and inversely with CD4 count (ρ = -0.50, P < 0.001). In contrast, PD-1 expression on CD8+ T cells was most strongly associated with CD8+ T cell activation and plasma viral load in viremic subjects (CD8+ T cell activation: p = 0.60, P < 0.001; VL: p = 0.30, P = 0.01).

Conclusions: PD-1 expression on CD4+ T cells is strongly associated with peripheral CD4+ T cell count and frequency of activated CD4+ T cells, while PD-1 expression on CD8+ T cells is associated with viremia and CD8+ T cell activation. Effective ART reduces PD-1 on both populations. Multiple mechanisms may account for the CD4+ T cell observations, including a potential role of homeostatic signals such as IL-7 causing proliferation and PD-1 expression. Prospective studies of anti-PD-1 antibody therapy will be needed to define whether PD-1 expression on CD4+ T cells is a cause or consequence of CD4+ T cell lymphopenia. Antigen-driven activation likely accounts for PD-1 expression on CD8+ T cells.

CD160 Is the Most Specific Co-Inhibitory Molecule Associated With CD8 T Cell Functional Impairment

Selena Vigano, Riddhima Banga, Florence Bellanger, Alex Farina, Denis Comte, Giuseppe Paritaleo, Matthieu Perreau

Division of Immunology and Allergy, Lausanne University Hospital, Lausanne, Switzerland

Background: Co-inhibitory molecules are commonly associated with T-cell dysfunction in the context of chronic viral infections such as HIV or HCV, however, their relative contribution in T-cell impairment remains unclear.

Methodology: In the present study, we evaluated the influence of expression of co-inhibitory molecules i.e. 2B4, PD-1 and CD160 on CD8 T-cell functions using the prototypic models of cleared (Flu) and persistent (EBV, CMV) virus infections.

Results: We hereby show that 2B4+CD160+PD-1+ and 2B4+CD160+PD-1+ CD8 T-cell populations are endowed with a reduced capacity to proliferate, produce IL-2 and IFN-γ, associated with a reduced capacity to express perforin, demonstrating that CD160+ CD8 T cells are functionally impaired, independently of PD-1 expression. In addition, the blockade of CD160/CD160-ligand interaction restored CD8 T-cell proliferative capacity and the level of CD8 T-cell proliferative restoration directly correlated with the ex vivo proportion of CD160 expression, demonstrating that CD160 signaling negatively regulates TCR-mediated CD8 T-cell signaling. Finally, in contrast to PD-1, CD160 expression was not up-regulated upon T-cell activation or proliferation.

Conclusions: Taken together, this study demonstrates that CD160 is the most specific T-cell dysfunction associated with CD8 T-cell dysfunctions.

Expansion of TIGIT-Expressing CD8+ T Cells Persists in Virally Suppressed HIV-1 Infection

Glen M. Chew1, Tsuyoshi Fujita1, Ravi Tandon1, Jeffrey N. Martin1, Steven Deeks2, Lishomwa C. Ndhlovu1

1Tropical Medicine, University of Hawaii, Manoa, Honolulu, HI, United States, 2University of California San Francisco, San Francisco, CA, United States

Background: HIV-1 infection induces a series of phenotypic and functional changes to T cells that eventually results in a state of T cell exhaustion. This immune dysfunction is defined by coordinate upregulation of negative immune checkpoints such as TIM-3 and PD-1. A detailed understanding of immune regulation of effector CD8+ T cells afford novel therapeutic strategies to halt or reverse HIV-1 progression and persistent inflammation. T-cell-ig-and-ITIM-domain (TIGIT) is a putative checkpoint blocker that upon engagement with its cognate ligand inhibits T cell function. The role of TIGIT in T cell exhaustion during HIV-1 disease progression remains uncharacterized.
Methodology: We assessed gene and surface expression of TIGIT, Tim-3, and PD-1 on CD8+ T cells derived from 60 HIV+ subjects [non-controllers (n=20), elite controllers (n=20) antiretroviral (ART) suppressed (n=20)] and 20 demographically matched HIV-1 uninfected adults in the SCOPE cohort study of well-characterized contemporary HIV-1 infected patients in San Francisco. Cryopreserved peripheral blood mononuclear cells (PBMCs) were phenotyped by multiparametric flow cytometry technology for TIGIT, Tim-3, and PD-1 expression, T cell differentiation, and in vitro T cell functional characteristics in response to anti-CD3 and anti-CD28 dynabead stimulation. RNA was isolated from PBMCs and relative gene expression was measured by real-time RT-PCR to determine gene transcription. Nonparametric Mann-Whitney Statistical t-Test were used.

Results: The expression of TIGIT on CD8+ T cells was highest in non-controllers (67.2%), intermediate in controllers (58.9%) and those on ART (49.2%) and lowest in HIV-1 uninfected (33.4%) (p = 0.0001, p = 0.0002, p = 0.0015 for comparisons of non-controllers, controllers and those on ART with HIV-1 uninfected, respectively). In contrast to PD-1 and TIM-3, the majority of TIGIT was highly expressed on effector memory (CD45RA+CD28-) CD8+ T cells. TIGIT mRNA relative expression levels were similarly elevated in non-controllers, controllers, and those on ART, compared to HIV-1 uninfected subjects.

In response to polyclonal stimulation, most of the IFN-γ responses were from TIGIT- CD8+ T cells (TIGIT- IFN-γ + 2.06% (0.91,5.8) vs. TIGIT+ IFN-γ + 0.49% (0.16,0.75); p = 0.035).

Conclusions: TIGIT is highly expressed on effector CD8 T cells, is actively transcribed and associated with reduced T cell function. These potentially dysfunctional cells persist during ART, suggesting that reversal of this pathway may be necessary during curative interventions.

286 PD-1 Expression Is Associated With Preserved CD4+ T Cell Homeostasis in Viremic Non-Progressors
Melicent C. Peck1, Elizabeth Sinclair1, Nichole R. Klaft1, Lorrie Eppling2, Jeffrey N. Martin3, Frederick M. Hecht1, Steven G. Deeks4, David Camerini1, Peter W. Hunt1
1Medicine, University of California San Francisco, San Francisco, CA, United States, 2Pharmaceutics, University of Washington, Seattle, WA, United States, 3Epidemiology & Biostatistics, University of California San Francisco, San Francisco, CA, United States, 4Medicine, University of California Irvine, Irvine, CA, United States

Background: Viremic non-progressors (VNPs) are a rare group of ART-naive, HIV-infected individuals that remain asymptomatic with normal CD4+ T cell counts for >10 years despite high-level viremia, similar to natural hosts of SIV infection. Like natural SIV hosts, VNPs also maintain very low levels of central memory CD4+ T cell (TCM) infection, but the effects of immunologic characteristics of this rare clinical phenotype are unknown.

Methodology: VNPs (n=9) were defined as: ART-naive, HIV duration >10 years, CD4+ T cell counts stably >500 cells/mm3 (and CD4% >15%), plasma HIV RNA levels (VL) stably >104 copies/ml, and absence of AIDS-defining illness. We compared them to recently HIV-infected participants (< 2 years post-infection) with similar CD4+ T cell counts and VL who were expected to progress at a typical rate (“putative progressors”, n=110), untreated HIV-infected progressors with similar VL, but CD4+ T cell counts <500 cells/mm3 (n=26), and HIV-uninfected controls (n=24). We compared T cell activation (CD38+HLA-DR+), maturation (CCR7, CD45RA), PD-1 expression, and HIV-specific functional responses between groups.

Results: VNPs were known to be HIV infected for a median of at least 22 years, and had higher median CD4+ T cell counts than both putative and chronic progressors (723 vs. 560 and 381, p ≤ 0.004), but also much higher CD8+ T cell counts (1737 vs. 859 and 986, p ≤ 0.001). VNPs had higher proportions of activated CD4+ and CD8+ T cells compared with HIV-uninfected controls (14% vs. 2% and 52% vs. 9%, p ≤ 0.001), comparable to putative and chronic progressors. The proportion of CD4+ T cells expressing PD-1 was higher in VNPs than putative progressors (24% vs. 16%, p = 0.006), driven by higher proportions of PD-1 expressing CD4+ TCM (CCR7-CD45RA+, p = 0.006) and TEM subsets (CCR7-CD45RA-, p = 0.01). Furthermore, in VNPs, the proportion of CD4+ T cells expressing PD-1 was associated with higher CD4+ T cell counts (r = 0.78, p = 0.02), while the opposite association was observed in chronic progressors (r = -0.62, p = 0.006). Despite a high proportion of CD4+ T cells expressing PD-1, VNPs had higher Gag-specific CD4+ T cell responses than putative progressors (TNFα+, p = 0.007). VNPs had lower proportions of PD-1 expressing CD8+ T cells than chronic progressors (p ≤ 0.05), and higher Gag-specific CD8+ T cell responses than putative and chronic progressors (TNFα+, p ≤ 0.05).

Conclusions: Despite maintaining normal CD4+ T cell counts and low levels of CD4+ TCM infection, VNPs have abnormally high T cell activation and CD4+ TCM PD-1 expression. This may suggest that sustained proliferation without productive infection of TCM may contribute to the VNP phenotype. Regardless of the mechanism, the immunology of VNP in humans appears fundamentally distinct from that in natural hosts of SIV.

287 PD-1 Homolog Expression Regulates Spontaneous Cytokine Production in HIV Infection
Preeti Bharaj, Harendra S. Chahar, Lizette Rodarte, Ogchechka Alcioe, Manjunath Swamy, Premilata Shankar
COE, Texas Tech University, El Paso, TX, United States

Background: Programmed death-1, is upregulated on immune cells in HIV infection and is considered to be a phenotypic marker for functional T cell exhaustion and immune dysfunction. Recently, another related, but distinct ligand PD-1H with a broad hematopoietic lineage distribution has been identified in mice. In this study we sought to examine the expression pattern and functional impact of the human orthologue of PD-1H on hematopoietic cells from normal and HIV infected individuals.

Methodology: PD-1H expression was determined by qPCR analysis of purified monocytes, T cells and B cells from PBMCs isolated from normal donors or HIV infected patients. FACS was done on PBMCs for PD-1H alongwith antibodies to identify monocytes, T cells and B cells. To study functional effects in monocytes, PD-1H-expressing or control plasmids were introduced by nucleofection. Cytokine levels were determined by cytometric bead array or ELISA. qPCR was used to determine the mRNA levels of IL-6, IL-1β and TNF-α. PBMCs from HIV infected subjects were co-stained for PD-1H and T cell activation markers. Effect of PD-1H overexpression or ablation on APC function of monocytes was determined by measuring HIV-gag-specific IFN-gamma response by ELISA.
**Results:** In normal donor PBMCs, highest expression of PD-1H was seen on monocytes followed by T lymphocytes and then B cells. Upon nucleofection, PD-1H in normal human monocyte/macrophages induced spontaneous secretion of multiple cytokines like IL-6, IL-8, IL-1β, and TNF-α. The effect was abrogated with PD-1H silencing using specific siRNA. Signaling was required as deletion of cytoplasmic domain abolished the spontaneous cytokine secretion. In HIV infected patients, PD-1H expression was also found to be highest on monocytes and expression levels were significantly higher than in normal monocytes. Further, activated monocytes expressed higher levels of PD-1H than classic or non-classic subset. PD-1H expression correlated highly with cytokine mRNA expression in monocytes and with expression of immune activation markers CD38 and PD-1 expression on both CD4 and CD8 T cells. Overexpression of PD-1H expression on monocytes enhanced their ability to induce IFN-γ secretion by HIV-specific T cells whereas silencing the molecule abrogated the effect.

**Conclusions:** PD-1H might play a pathogenic role in HIV-induced immune activation and thus provides a potentially new target for therapeutic intervention.

**288  HIV Virulence Has Not Increased in the UK Subtype B Epidemic**

Emma B. Hodcroft1, Jarrod Hadfield1, Esther Fearnhill2, Andrew Phillips3, David Dunn3, Deenan Pillay4, Andrew Leigh Brown5, UK HIV Drug Resistance Database

1Institute of Evolutionary Biology, University of Edinburgh, Edinburgh, United Kingdom, 2Department of Zoology, University of Oxford, Oxford, United Kingdom, 3MRC Clinical Trials Unit, London, United Kingdom, 4Infection and Population Health, University College London, London, United Kingdom, 5Research Department of Infection, University College London, London, United Kingdom

**Background:** The question of whether HIV is evolving and perhaps becoming more virulent has received considerable attention. Two recent meta-analyses have estimated an increase in set-point viral load (spVL), a predictor of disease progression, of 0.044 log10 copies/mL/year and 0.013 log10 copies/mL/year, interpreted by both studies as an increase in virulence that could be caused by viral factors. This would require that the viral genome exerted substantial influence over the spVL, i.e., spVL having high heritability. Previously we estimated this to be only 5% in the UK subtype B epidemic.

Change in spVL over time could be influenced by selection. Transmission and extinction events, on the lineage down which spVL is evolving, exert between-lineage selection, and within-lineage selection occurs at the individual level, as spVL is correlated with probability of transmission. Here we implemented quantitative genetics methods to estimate change in spVL due to between- and within-lineage selection on the viral genome.

**Methodology:** 8,483 pre-ART subtype B sequences with corresponding spVL were analysed. A phylogenetic tree was reconstructed from the resistance-site stripped sequences in RAxML. The phylogeny and spVL were fitted in a mixed model with age, sex, ethnicity, time since diagnosis, and year of diagnosis as fixed effects and year of diagnosis and country of origin as random effects.

Within-lineage change can be estimated from longitudinal data by adding sequence sample date as a covariate in the model. Between-lineage selection can be estimated by looking at the difference in predicted genotypic potential (“breeding value”) over time. We used Markov chain Monte Carlo methods to obtain a posterior distribution of evolutionary change by averaging over uncertainty in the estimates. To determine whether any change that has occurred is greater than would be expected by chance (drift), we used posterior predictive tests.

**Results:** We estimated a small change in spVL due to between-lineage selection of 0.002 log10 copies/mL/year, which this was not significantly different from what could be expected due to drift. Our estimate of the change in spVL due to within-lineage selection and environmental effects was small but significant at -0.05 log10 copies/mL/year.

**Conclusions:** Our estimate of the change in spVL over time, although small, is significant but negative. This is based on the first direct estimate of the viral contribution to spVL across an epidemic and gives no support to the view that virulence in HIV is increasing. However, we previously showed that most of the phenotypic value of spVL in our model is determined by fixed effects (age, sex, time to diagnosis, etc.) which themselves have changed over the epidemic and propose this is a more probable source of the observed change.

**289  Subjects Infected With Clade C-Containing HIV Exhibit Higher CD4+ T Cell Activation**

Priscilla R. Costa1, Wendy Hartogensis2, Ricardo S. Diaz3, Peter Bacchetti2, Rick Hecht2, Breno R. Santos3, AMPLIAR study team, Esper G. Kallas1, Emma B. Hodcroft1

1Institute of Evolutionary Biology, University of Edinburgh, Edinburgh, United Kingdom, 2Department of Zoology, University of Oxford, Oxford, United Kingdom, 3MRC Clinical Trials Unit, London, United Kingdom

**Background:** Cellular activation has been implicated in the progressive immunodeficiency and the development of end-organ disease in HIV-1 infection. Recent studies have shown that HIV subtypes may differ in loss of CD4+ T cells and viral load over time. Genetic differences in LTR, Nef, Tat, and Vpu may play important roles in HIV transmission and immunopathogenesis, and may differ in HIV strains from clade C vs. those from other clades. We hypothesized that individuals infected by clade C (or C-containing recombinant strains) would have different cell activation status than non-C-containing HIV-infected subjects.

**Methodology:** Sixty-three Brazilian subjects recently infected by HIV were studied and divided into two groups: a “C” Group (n=20) included those with clade-C-containing virus (subtypes C, BC, CU, CK, CRF_31BC, CRF31-like, CRF40-like, and Complex), and a “non-C” group (n=43) infected by subtypes B, BF, BF1, F1, and CRF02 AG. From each subject, peripheral blood mononuclear cells (PBMC) were analyzed from acute infection (<3-6 months) and after virologic set point (approximately six months later), prior to ART. Samples were analyzed to characterize T cell activation and maturation markers (CD38, HLA-DR, CD27, CD45RA, and CCR7) using multiparametric flow cytometry.
Results: HIV viral load, CD4+ T cell count and activation (percentage CD38+ HLA-DR+) expression in total CD4+ T cells) were similar between C and non-C groups during acute infection. In the C group, but not in the non-C group, CD4+ activation increased substantially between acute infection and set point. At the set point (follow-up) visit, CD4+ T cell activation was statistically significantly higher in the C group in T cell subsets including naïve (CD45RA+ CD27+CCR7+) (p = 0.005), central memory (CD45RA-CD27+CCR7+) (p = 0.003), effector t. (CD45RA+CD27-CCR7-) (p = 0.002), and effector memory (CD45RA-CCR7-CD27-) (p = 0.005) subsets. In multivariate models, differences in CD4+ CD38+HLA-DR+ expression remained statistically significant after controlling for baseline CD4+ and HIV viral load, gender, and transmission route/risk group.

Conclusions: Infection with clade-C-containing HIV-1 strains circulating in Brazil effect was associated with higher levels of CD4+ T cell activation than infection with non-C containing HIV-1, which emerged shortly following acute infection. This effect was independent of CD4+ T cell counts, HIV viral load, sex and infection route. These finding may have implications for how subtype C causes HIV disease progression, end-organ disease and HIV transmission.

Correlative Marker Studies

290 Telomere Length Predicts Immunological Recovery in Older HIV Patients Treated With cART

Jose-Ramon Blanco1, Inciudacila Jarrin2, Alfredo Martinez2, Eva Siles3, Ana Canuelo3, Felix Gutierrez3, Jorge del Romero3, Jesus Santos3, Santiago Moreno3, CoRIS
1Hospital San-Pedro-CIBER, Logroño, Spain, 2ISCIII, Madrid, Spain, 3Department of Experimental Biology, University of Jaen, Jaen, Spain, 4Hospital Ramón y Cajal, Madrid, Spain

Background: Successful cART does not always recover CD4 T-cells despite the effective control of HIV-1 replication. Telomeres are DNA-protein structures essential to chromosomal stability and replication. Telomere length (TL) is probably regulated by oxidative stress. Because little is known about the impact of TL on the immunorecovery we evaluated the relationship between TL and immunorecovery at 48 weeks after cART initiation in patients virologically suppressed.

Methodology: CoRIS is an open, prospective, multi-centre cohort of HIV-positive subjects. We selected those on stable cART who achieved a VL<50 cop/ml after 48 weeks of their first cART. Immunorecovery was defined as an increase in CD4+ cells by >100 cells/ml compared to baseline. Leukocyte TL was measured using a quantitative PCR technique and categorized into tertiles (<0.13 for the lowest, 0.13-0.27 for the middle and >0.27 for the highest telrite). Nitric oxide levels were quantified by determining nitrate/nitrite and S-nitroso compounds using an ozone chemiluminescence-based assay. Lipid peroxidation was measured by quantification of thiobarbituric acid reactive substances. Multivariate logistic regression models were used to estimate odds ratios (OR) and its 95% confidence intervals (CI) for association between TL and the odds of achieving immunorecovery adjusting for sex, age at cART initiation (years) (<50 and ≥50) and CD4+ count at start of cART (cells/ml) (<200, ≥200). Additional adjustment for nitrosative and oxidative stress was also carried out. We assessed whether this association was different in patients aged <50 and ≥50 years at cART initiation by including interaction terms into models.

Results: Of 132 patients included, 86% were male and 81% <50 years at cART initiation. We failed to find an association between TL, and immunorecovery overall (p = 0.47) but found an interaction between TL and age at cART initiation (p = 0.008): while no association was seen in patients <50 years (p = 0.18), in those ≥50 the odds of achieving immunorecovery decreased with decreasing tertiles of TL (OR [95% CI] for middle and lowest tertiles were 0.50 [0.05-4.84] and 0.13 [0.03-0.63], respectively). Additional adjustment for nitrosative and oxidative stress did not change results.

Conclusions: Short TL in HIV-infected patients ≥50 is related to a lower immunorecovery in spite of the successful virological control.

291 The Clinical Impact of Viral Load Copy Years in Antiretroviral-Naive HIV Serocounters

Matthias an der Heiden1, Alexander Zoufaly2, Caroline Sabl3, Jan van Lunzen4, Hans-Jürgen Stellbrink5, Barbara Gunsenheimer-Bartmeyer6, Philippe Vanhems7, Santiago Perez-Hoyos7, Geneviève Chêne8, Osamah Hamouda1, on behalf of CASCADE Collaboration in EuroCoord
1Infectious Disease Epidemiology, Robert Koch-Institute, Berlin, Germany, 2Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany, 3Institute of Epidemiology & Health, University College London, London, United Kingdom, 4Infectiologie, Universitätshôpital, Hamburg-Eppendorf, Hamburg, Germany, 5Institut für Medizinische Mikrobiologie und Infektionsbiologie, Universität Göttingen, Göttingen, Germany, 6Infection Control, Centre Hospitalier Universitaire de Lyon, Lyon, France, 7Servei de Medicina Preventiva i Salut Publica, Institut de Recerca Hospital Vall Hebrón, Barcelona, Spain, 8Instituut de Santé Publique, d’Épidémiologie et de Développement, Université Victor Segalen Bordeaux 2, Bordeaux, France

Background: Ongoing viral replication may contribute to immune activation which may have deleterious effects additional to CD4 loss before antiretroviral therapy (ART) is started. A measure of the cumulative exposure to HIV replication (viral load copy years, VCY) may therefore add important prognostic information in chronic HIV infection.

Methodology: Data from CASCADE, a cohort collaboration of HIV-1 serocounters, were used. All ART-naïve patients >15 years with seroconversion (SC) dates after 1997, who had viral load (VL) and CD4 measured within 4-12 months following SC were included. Patient follow-up began 4 months after SC and was censored at earliest of ART start, CD4 <200 cells/μl or when there were no VL and CD4 measurements for >12 months. VCY was approximated by the time-updated product of VL and the duration to the next VL measurement. A multivariable Poisson model with outcome clinical AIDS or death was also carried out. We assessed whether this association was different in patients aged <50 and ≥50 years at cART initiation by including interaction terms into models.

Results: Of 132 patients included, 86% were male and 81% <50 years at cART initiation. We failed to find an association between TL, and immunorecovery overall (p = 0.47) but found an interaction between TL and age at cART initiation (p = 0.008): while no association was seen in patients <50 years (p = 0.18), in those ≥50 the odds of achieving immunorecovery decreased with decreasing tertiles of TL (OR [95% CI] for middle and lowest tertiles were 0.50 [0.05-4.84] and 0.13 [0.03-0.63], respectively). Additional adjustment for nitrosative and oxidative stress did not change results.

Conclusions: Short TL in HIV-infected patients ≥50 is related to a lower immunorecovery in spite of the successful virological control.
**Results:** Of 5770 patients with 13,330 years of follow-up, 110 (2%) acquired AIDS or died, 2351 (59%) started ART and CD4 count dropped below 200 cell/μl in 160 patients. In the adjusted Poisson model, older age (rate ratio 1.04 per year [95% confidence interval 1.02-1.06]), injection drug use (2.76 [1.25-6.10]) and having a CD4 count of 200-350 cells/μl (rate ratio 1.93 [1.16-3.23]) compared to 500-1000 cells/μl were associated with a higher rate of clinical AIDS or death. Compared to VCY category 20,000-50,000 copies×y/mL, rates of clinical AIDS/death were higher for those with VCY 100,000-200,000 copies×y/mL (2.4 [1.1-5.2]) and >200,000 copies×y/mL (4.9 [2.3-10.1]). Modelling log10(VCY) continuously using B-splines in the otherwise unchanged Poisson model is depicted in Figure 1 for 25 year old males with a CD4 count of 350-500 cells/μl and current VL > 60,000 copies/mL.

**Conclusions:** VCY appears to provide prognostic information on the risk of clinical AIDS/death additional to current VL and CD4 in naive patients. Choice on when to start ART may also be influenced by the duration and extent of previous HIV replication.

**Interleukin-32: Expression, Interaction With IFN, and Clinical Significance in HIV-1 Infection**

Carolina Scagnolari¹, Katia Montenleone¹, Carla Selvaggi¹, Francesca Falasca¹, Pierluigi Di Maio¹, Ivano Mezzaroma², Gabriella d’Ettorre³, Ombretta Turriziani¹, Guido Antonelli¹

¹Molecular Medicine, Sapienza University of Rome, Rome, Italy, ²Department of Clinical Medicine, Sapienza University of Rome, Rome, Italy, ³Department of Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy

**Background:** Given the growing evidence for a role of interleukin-32 (IL-32) in the immune response to HIV-1 infection, and its interplay with type I and III interferons (IFNs), we studied the gene expression of IL-32 isoforms (α and nonα) in untreated chronically HIV-1-infected patients and in gender- and age-matched healthy individuals. To further characterize both the anti-HIV properties of IL-32 and the cytokine’s relationship with host antiviral innate immune responses, we evaluated whether IL-32 can induce ex vivo the expression of antiviral IFN-induced genes (ISGs), namely Myxovirus resistance A (MxA), and apolipoprotein B mRNA-editing enzyme-catalytic (APOBEC)3G and APOBEC3F. We also investigated whether in vivo IL-32 isoform levels were correlated with those of MxA and APOBEC3G/3F. Furthermore, since the activity of IL-32 is regulated by microRNA29b, we evaluated the relationship between IL-32 levels and microRNA29b expression.

**Methodology:** PBMCs from 98 HIV-1 subtype B -infected patients, naïve for antiretroviral treatment, attending the Policlinico Umberto I Hospital in Rome over the seven year period 2005-2012 were included in this study. The CD4+ T cell count was between 83 and 1,300 cells/mm3; the plasma viral load ranged from 300 to 1,805,000 HIV-RNA copies/ml. Blood samples from 36 healthy individuals were also included in this study. Expression of IL-32 subtypes was evaluated using RT-Real Time PCR. Comparison of quantitative values were assessed by Mann Whitney test, and Sperman correlation using SPSS 17 Software.

**Results:** Results indicated that mRNA levels of both IL-32α and IL-32nonα were significantly higher in chronically HIV-1-infected patients than those measured in the control group. We observed a significant negative correlation between the gene expression of IL-32 isoforms (α and nonα) and HIV-RNA levels measured in plasma but not with the CD4+ T cell count. Our ex vivo studies disclosed that ISGs mRNA levels were significantly increased after IL-32 treatment of PBMCs. Interestingly, our results indicated significant positive correlations between transcript levels of IL-32 subtypes and those of MxA, APOBEC3G and APOBEC3F measured in PBMC collected from HIV-1-infected patients. In contrast we failed to detect any significant association between levels of IL-32 subtypes and microRNA29b expression.

**Conclusions:** Overall our results demonstrated that IL-32 isoforms are highly expressed during chronic HIV-1 infection and that IL-32 through the induction of IFN stimulated genes and host restriction factors could have a central role in the antiviral immune response against HIV-1.
293  TNFα in Viral Control and Early Disease Progression in Patients With HIV-1 Infection

Sagar A. Vaidya1, 2, Christian Korner1, Michael Sirignano1, Molly Amed1, Sue Bazner1, Jenna Rychert2, Todd Allen1, Eric S. Rosenberg2, Ronald J. Bosch3, Marcus Altfeld1, 4
1The Ragon Institute of MGH, MIT, and Harvard, Cambridge, MA, United States, 2Division of Infectious Diseases, Massachusetts General Hospital, Boston, MA, United States, 3Harvard School of Public Health, Boston, MA, United States, 4Department of Viral Immunology, Heinrich Pette Institute, Hamburg, Germany

**Background:** Inflammatory biomarkers are associated with increased morbidity/mortality in chronic HIV-1 infection, however, their role in early HIV-1 disease is poorly understood. We hypothesized that inflammatory biomarkers in early infection are associated with the subsequent viral load set point (VLSP) and the time to reach early clinical measures of HIV-1 disease progression.

**Methodology:** A longitudinal retrospective analysis was conducted of 90 patients with untreated primary HIV-1. VLSP was determined for all study subjects during the first year post-infection and their plasma was tested for TNFα, IL-6, CRP, Dimer-1, and IFNα. Primary endpoints were VLSP and days to CD4+ T cell count < 500 cells/mm³, secondary endpoints were days to CD4+ T cell count < 350 cells/mm³ and days to antiretroviral therapy (ART) start.

**Results:** Only TNFα was significantly correlated with VLSP (R = 0.48, p < 0.0001, Spearman-rank) and CD4+ T cell count (p = 0.046, Mann-Whitney). Log rank analysis separating the groups by mean TNFα (≥ 8.5 pg/mL) showed significant difference for days to CD4+ T cell count < 500 cells/mm³ (p = 0.006, median days to endpoint of 208 versus 1218 in the high and low TNFα groups, respectively) and for days to ART start (p = 0.049, median days to endpoint of 439 versus 1057 in the high and low TNFα groups, respectively). Cox proportional hazard ratios for days to CD4+ T cell count < 500 cells/mm³ in the high versus low TNFα groups were 3.1 in univariate analysis (CI 1.3-7.1, p = 0.008), 1.9 (CI 0.8-4.7, p = 0.15) when adjusted for concurrent viral load, and 5.1 (CI 1.9-13.5, p = 0.001) when adjusted for concurrent CD4+ T cell count.

**Conclusions:** High plasma levels of TNFα in early HIV-1 infection are associated with poorer viral control as well as decreased time to reach CD4+ T cell count < 500 cells/mm³ and initiation of ART in our cohort. This finding was independent of concurrent CD4+ T cell count and therefore may be relevant for identification of patients at higher risk of early HIV-1 disease progression.

294  Monocyte Activation Markers in HIV Infected Subjects: A Biomarker for HIV Immunotherapy

Joumana Zeidan1, Elizabeth Sinclair2, Gary Lee3, Shelley Wang1, Martin Gedlin4, Geoff Nichol5, Winson Tang6, Steven Deeks5, Dale Ando1, Rafick-Pierre Sekaly1
1VGTI Florida, Port St. Lucie, FL, United States, 2UCSF, San Francisco, CA, United States, 3Sangamo Biosciences, Richmond, CA, United States

**Background:** Immune activation persists among treated HIV infected individuals and is associated with suboptimal CD4+ T cell recovery and excess morbidity and mortality. Activation of both adaptive (T cells) and innate immune systems are known to be pathogenic in treated HIV disease. This chronic inflammation may also impact outcomes of immune-modulatory and gene-modified cell therapies. In order to better define the optimal host environment for cure-related gene therapy studies, we explored the impact of well-controlled HIV infection on the phenotype and activation of monocytes.

**Methodology:** Peripheral blood mononuclear cells (PBMCs) collected from fifteen ART controlled aviremic HIV infected subjects (age range = 22-56, CD4 count range = 506-1656) and fifteen HIV negative subjects (age range = 19-54) were evaluated. Markers associated with T-cell activation (HLA-DR, CD40, and CD86) were assessed on three monocyte subsets (CD14hi, CD16−; CD14+, CD16−; and CD14+, CD16+).

**Results:** Statistically significant greater levels of activation, as defined by expression of HLA-DR, CD40 and CD86 molecules, were observed on monocytes from HIV infected subjects despite long term control of viral load. For the CD14hi, CD16− subset, the mean percent of activated monocytes, as defined by the co-expression of HLA-DR, CD40 and CD86, was 43% (95% CI = 33-54%) and 25% (95% CI = 16-33%) for the HIV infected group and HIV negative group respectively (p = 0.008). Similarly, the level of monocyte activation in the CD14+, CD16+ (Fcγ receptor) monocyte subset was higher in the HIV infected group, 66% (95% CI = 57-75%) versus 39% (95% CI = 30-48%) in the HIV negative group (p = 0.0001). The HIV infected group significantly express a higher level of CD163 (scavenger receptor) (p < 0.0001), another marker of monocyte/macrophage activation. The expression levels of all activation markers (by mean fluorescent intensity) were higher in all monocyte subsets in the HIV infected group.

**Conclusions:** Even among an optimally treated group of HIV-infected adults (as defined by viral load and high CD4+ T cell counts), HIV infected subjects showed elevated expression level of the immune activation markers in multiple monocyte subsets, as compared to HIV negative individuals. We have previously found that monocyte activation (as defined by co-expression of HLA-DR, CD40, and CD86) predicted poor long term CD4 reconstitution (r = -0.75; p = 0.03) in immunologic non-responders after infusion of SB-728-T (autologous ZFN mediated CCR5 gene disrupted CD4+ T cells). These results should provide guidance for identifying HIV infected individuals who may have a more intact immune system and thus more suitable for HIV immunotherapy.

295  Down-Regulation of CD39/CD73 On B Cells of HIV Patients Coincides With a Disturbed Ig Class Switch

Eun-Seong Kim1, Ilona Töth1, Claudia Beisel1, Johanna Eberhard1, Silke Kummer1, Ansgar W. Lohse1, Friedrich Haag2, Jan van Lunzen1, Julian Schulze zur Wiesch1
1I. Department of Internal Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, 2Institute of Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

**Background:** So far, the antibody independent role of B-cells in HIV infection has not sufficiently been characterized. Recently, it has been described that down-regulation of CD39 on B cells in CVID patients correlates with a defective Ig-switch (F. Schena et al Cell Reports 2013). Here, we investigate the surface expression of two ectonucleotidases, CD39 and CD73, of different B cell subpopulations in HIV infection with regards to their class-switch properties.

**Methodology:** Peripheral (n=52) and lymph nodal B cells (n=10) of HIV infected patients at different stages of disease as well as uninfected controls (n=14) were analyzed via multi-color flow cytometry for their differentiation-(CD19, CD20, CD21, CD27, IgG, IgM, CD39, CD73 and CD26), activation and
exhaustion status (CD38 CD86, PD-1, Ki-67). Furthermore, functional assays were performed with these B cells to assess the cytokine pattern (IL4, IL10, IL13). Then, we compared these data with clinical parameters as well as plasma IgG1-4 and IgM levels.

Results: Overall, we find high expression of CD39 and CD73 on B cells of healthy controls. HIV Elite controller patients display comparable CD39 and CD73 expression on their B cells to healthy controls, while chronic untreated HIV patients show a significant down-regulation of both enzymes (p=<0.0001). Subanalysis of naive and memory B cell subsets revealed, that CD39/CD73 down-regulation can be observed in every naive/memory subset, apart from the IgM memory subset. CD39 and CD73 expression partly recovered after initiation of ART. We find significantly increased IgM expression (untreated p= 0.0001, ART p=0.0231) in both ART and viremic patients compared to healthy controls. However, in ART patients we observed a significantly higher expression of IgG compared to viremic patients as well as healthy controls (p=0.0014) indicating class-switch recovery.

Conclusions: Untreated, viremic HIV patients with impaired class-switched antibody responses are selectively deficient in the CD73 expression of their B cells, suggesting that lack of CD73-dependent adenosine generation leads to a shift in IgG class switch and contributes to the pathogenesis of this disease.

296 Transcriptional Signatures of CD4 T Cell Subsets and Control of HIV Reservoirs in Elite Controllers
Adele de Masson1, Amos Kirilovsky1, Rima Zoorob1, Veronique Avettand-Fenoel1, Veronique Morin1, Anne Oudin1, Benjamin Descours1, Christine Rouzioux2, Brigitte Autran1, the ALT ANRS-Co15 Study Group
1Immunology, Université Pierre et Marie Curie - Paris 6, UMR S945, Laboratory Immunity and Infection, INSERM, U945, Laboratory Immunity and Infection, Paris, France, 2Immunology, Paris-Descartes University, Sorbonne Paris-Cité, EA 3620, Virology Laboratory, Necker Enfants-Malades Hospital, Paris, France

Background: Understanding the molecular mechanisms associated with the exceptional quasi-equilibrium between HIV reservoirs and host cells in the model of functional cure represented by Elite Long-Term Nonprogressors (E-LTNPs) should provide clues for developing strategies to purge the HIV reservoirs but remain to be elucidated.

Methodology: We compared the whole-genome transcriptional profiling of the 4 major resting (CD25-CD69-DR-) CD4 T cell subsets (naïve [TN], central-memory [TCM], transitional-memory [TTM] and effector-memory [TEM]) sorted from PBMCs of 14 HIV-1 infected individuals including 7 E-LTNPs, 7 viremic LTNPs (Vir-LTNPs) and 7 uninfected individuals (UI). Total HIV DNA was quantified in each T cell subset by real time quantitative polymerase chain reaction (qPCR, Biocentric, Bandol, France). The transcriptomes were analyzed using an Illumina Platform. Statistics were performed using the Limma package of R. Differentially expressed genes (DEGs) were considered significant with a false-discovery rate (FDR) below 0.05. Key molecular signatures were quantified by qPCR in each sorted CD4 T cell subset in parallel to the HIV-1 cellular DNA and unspliced RNA levels.

Results: Resting TCM and TTM were the main contributors to the HIV reservoir in LTNP's with a 1-log difference for each subset HIV-DNA content between E-LTNPs and Vir-LTNPs. When comparing each E-LTNP, Vir-LTNP and UI CD4 T cell subset transcriptome to a single comparator (UI-TN), an increasing gradient of DEGs followed the linear TN to TCM, TTM and TEM differentiation model. Distinct profiles were however observed between groups with the most active and distant transcriptomes in TCM from E-LTNPs but in TEM from Vir-LTNPs. Most DEGs encoded proteins with functions related to intracellular signaling, adherence, cytotoxicity and apoptosis. The E-LTNPs TCM, representing the main CD4 compartment, revealed 2 major specific signatures compared to TCM from Vir-LTNPs and UI: (i) TCR and costimulation signaling genes with 8 overexpressed and 2 down-modulated DEGs, and (ii) type I interferon-related genes with 5 down-modulated and 2 upregulated DEGs. This specific E-LTNPs transcriptome was associated to extremely low levels of HIV-DNA and HIV-RNA transcripts in TCM from E-LTNPs compared to other subsets and to TCM from Vir-LTNPs with significant association between host and HIV genes.

Conclusions: Resting CD4 TCM from E-LTNPs display a unique transcriptional profile with key host genome signatures from the TCR/costimulatory signaling and IFN-I pathways associated to low levels of HIV reservoirs and HIV-RNA transcription. These results allow identification of new molecular targets associated with the control of the HIV reservoirs in models of functional cure.
298 Elite Suppressor CD4+ and CD8+ T Cells Suppress Viral Replication in Monocyte-Derived Macrophages

Victoria E. K. Walker-Sperling1, Robert W. Buckheit2, Robert F. Siliciano3, 4, Joel N. Blankson3

1Immunology Graduate Program, The Johns Hopkins School of Medicine, Baltimore, MD, United States, 2National Cancer Institute, Frederick, MD, United States, 3Department of Medicine, The Johns Hopkins School of Medicine, Baltimore, MD, United States, 4Howard Hughes Medical Institute, Chevy Chase, MD, United States

Background: Elite suppressors (ES) are HIV-1 infected patients who maintain undetectable viral loads without antiretroviral therapy. The control has previously been associated with a qualitatively superior CD8+ T cell response to infected CD4+ T cells. However, very few studies have examined the effector T cell response to HIV-1 infected macrophages. In the macaque ES model, both CD4+ and CD8+ T cell clones are capable of suppressing infection in macrophages, but in an ex vivo study, SIV-specific primary CD8+ T cells were far less effective at inhibiting viral replication in macrophages than in CD4+ T cells. In this study, we examined the CD4+ and CD8+ effector T cell responses to HIV-1 infected monocyte-derived macrophages (MDM).

Methodology: Monocytes were isolated from 10 uninfected healthy donors (HD) and 7 ES and cultured in macrophage differentiation media (RPMI, 20% human AB serum, 1% HEPES, 50 ng hrM-CSF/mL) for 7 days before infection. ON the day of infection, the MDMs were infected with the laboratory isolate Ba-L by spinoculation. Unstimulated primary CD4+ and CD8+ cells isolated from a second blood draw were added to the MDMs at various effector to target ratios immediately after infection. Normalized percent inhibition of viral replication was calculated by comparing culture supernatant p24 levels in the presence and absence of effector CD8+ or CD4+ T cells, and unpaired, two-way Student’s T-tests were used to determine statistical significance.

Results: There was no difference in the rate of viral replication in MDMs isolated from ES and HD (p > .7). ES effector T cells were capable of suppressing viral production in MDMs. By day 7, CD4+ effector T cells inhibited viral production in MDMs by 56.8 ± 11.2% (mean ± SE; range: 23.0-92.7%), and CD8+ effector T cells inhibited viral production in MDMs by 84.4 ± 9.2% (range: 36.0-99.3%), with the CD8+ effect trending to be stronger (p < .1). Conversely, inhibition in HD was significantly lower with an average inhibition of 17.1 ± 8.2% and 12.4 ± 7.7%, respectively (CD4s: p < .02, CD8s: p < 10^-4). These differences were apparent as early as the third day post infection (p < .05). Interestingly, separation of effector cells from target cells with transwells resulted in complete abrogation of the inhibitory response by CD8+ T cells and partial abrogation of the CD4+ T cell response.

Conclusions: Primary unstimulated effector CD4+ and CD8+ T cells from ES are capable of effectively inhibiting viral replication in MDMs in vitro in a cell-cell contact mediated manner. The degree of CD8+ T cell mediated inhibition of viral replication in MDMs was comparable to that seen in target CD4+ T cells. These observations imply that the response of effector cells to macrophages should be considered in rational vaccine design and the continuing goal of eradication.

299 Effective Control of Virus Replication in HIV-1 Elite Controllers by Active SAMHD1

Eduardo Pauls1, Alba Ruiz1, Beatriz Møthe1, Manel Crespo1, Menéndez-Arias Luis1, Bonaventura Clotet1, Oliver T. Keppel4, Francesc Posas1, Christian Brander1, 6, José A. Esté1

1IrsiCaixa AIDS Research Institute, Hospital Germans Trias i Pujol, Universitat Autònoma de Barcelona, Badalona, Spain, 2Infectious Diseases, Hospital Universitari Vell d’Hebron, Barcelona, Spain, 3Centro de Biología Molecular Severo Ochoa, Consejo Superior de Investigaciones Científicas, Universidad Autónoma de Madrid, Madrid, Spain, 4Institute of Medical Virology, University of Frankfurt, Frankfurt, Germany, 5Cell Signaling Unit, Departament de Ciències Experimentalis i de la Salut, Universitat Pompeu Fabra, Parc de Recerca Biomèdica de Barcelona, Barcelona, Spain, 6Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain

Background: Elite suppressors (ES) are HIV-1 infected individuals who control infection and remain healthy without the need for antiretroviral therapy. The basis of this elite control of infection remains unclear. SAMHD1 has been identified as an HIV-1 restriction factor that controls the intracellular deoxynucleotide pool, limiting HIV-1 reverse transcription. SAMHD1-mediated restriction is counteracted by HIV-2 Vpx and is deactivated by cyclin-dependent kinase (CDK)-mediated phosphorylation.

Methodology: Purified CD4+ T cells from healthy donors (n=11), viremic HIV+ patients (n=10) and elite controllers (n=12) were stimulated and infected with HIV-1 or HIV-2 strains in the presence or absence of coexpressed Vpx. Replication levels were measured by flow cytometry and proviral DNA measured by quantitative PCR (qPCR). Gene and protein expression were measured by mrqNA qPCR and Western blot analysis respectively. Cell activation was measured by analysis of CD25 and CD69 expression and proliferation by Ki67 expression and absolute cell count. Unpaired t test was used for statistical analysis.

Results: Despite similar levels of CD4+ T cell activation and proliferation than control cells, anti-CD3 stimulation of CD4+ T cells from elite controllers showed an intrinsic resistance to infection (p<0.0001) at the level of unintegrated proviral DNA formation (p=0.0023) that was overcome by coexpression of HIV-2 Vpx, indicating that restriction was mediated by SAMHD1. HIV-1 infection of CD4+ T cells from healthy donors correlated with the degree of phosphorylation of SAMHD1 (r2=0.7437) measured by Western blot. Moreover, cells from elite controllers showed significantly (p<0.0001) lower levels of SAMHD1 phosphorylation compared to healthy donors or cells from viremic HIV+ individuals. RNA interference or pharmacological intervention showed that CDK2 and CDK6 control SAMHD1 phosphorylation in primary hematopoietic cells. Moreover, CD4+ T cells from elite controllers showed lower mRNA expression of CDK2 (p<0.0001) and CDK6 (p=0.0085) concomitant to reduced activation of CDK2 as measured by CDK2 Thr160 phosphorylation.

Conclusions: These results provide a mechanism of viral control common to HIV-1 elite controllers linking virus replication and cell cycle regulation, and suggest that SAMHD1-mediated restriction may be relevant in vivo as a determinant of HIV-1 disease progression and control.
Effect of Raltegravir Intensification in the Cytokine Profile of Treated HIV+ Individuals

Marta Massanella1, Josep M. Llibre2, Silvia Martíl1, Maria C. Puertas3, Jordi Puig1, Eugènia Negredo1, Douglas D. Richman4, 5, Javier Martinez-Picado6, Bonaventura Clotet2, 3, Julià Blanco2

1Pathology, University of California San Diego, La Jolla, CA, United States, 2Lluita contra la Sida Foundation, Badalona, Spain, 3AIDS Research Institute IrsiCaixa, Institut d’Investigació en Ciències de la Salut Germans Trias i Pujol, IGTP, Badalona, Spain, 4University of California San Diego, La Jolla, CA, United States, 5Veterans Affairs San Diego Healthcare System, La jolla, CA, United States

Background: Inflammatory markers are increased in untreated HIV infected individuals and, as immune activation, are not normalized by combination antiretroviral therapy (cART). Long term (48 weeks) intensification of cART with Raltegravir reduced CD8 T-cell activation in the Discorral and IntegRal studies. Therefore, we have evaluated the effect of Raltegravir intensification in several soluble plasma markers in these studies.

Methodology: Longitudinal plasma samples (0-48 weeks) from the Integral (67 individuals with high CD4 T-cell counts, 22 control and 45 intensified individuals) and the Discorral studies (44 individuals with CD4 T-cell counts >350 cells/μL, 14 control and 30 intensified individuals) were analyzed using a BioRad Multiplexed cytokine array covering 22 markers. Mann-Whitney, Wilcoxon and Spearman tests were used for analysis.

Results: Before intensification, individuals enrolled in the Discorral Study (median CD4 T-cell counts 248 cells/μL) showed a significant higher level of most inflammatory cytokines when compared with individuals enrolled in the IntegRal study, which had a median CD4 T-cell counts of 520 cells/μL. Main differences were observed in pro-inflammatory cytokines IP10 (p=0.001), IL-1b (p=0.006), IL-12 (p=0.006), IL-13 (p=0.0001), IL-17 (p=0.0084) and TNFa (p=0.0024), apoptosis mediators such as TRAIL (p=0.0024) or homeostatic cytokines as IL-7 (p=0.0009). Consistently, significantly negative correlations between most of these markers and CD4 T-cell counts were found: IP10 (r²=0.074), TRAIL (r²=0.074), IL-17 (r²=0.064), IL-1b (r²=0.06) and IL-13 (r²=0.06), p<0.02 in all cases. Moreover, a marker of endothelial function, sVCAM-1, was negatively correlated with CD4 T-cell counts (r²=0.06, p=0.009). Longitudinal analysis showed that 48-week raltegravir intensification failed to induce significant changes in cytokine levels in individuals with high CD4 T-cells (IntegRal study) although significantly reduced some of the cytokines increased in individuals with low CD4 T-cell counts (Discorral study) at week 48, especially IP10 (p=0.03) and a trend was observed with TNFa (p=0.09).

Conclusions: Inflammatory profile is strongly associated with the level of CD4 T-cells in long term cART treated HIV infected individuals. Raltegravir intensification has little effect on these markers, although a positive impact could be observed in individuals with poor CD4 T-cell recovery.

Analyses of HIV-1 Viral Dynamics During Treatment With a Regimen Including an Integrase Inhibitor

Jeremie Guedj1, Ruy Ribeiro2, Adriana Andrade3, Susan L. Rosenberg4, Darlene Lu5, Douglas Richman6, Mathew Strain7, John Mellors6, Daniel R. Kuritzkes7, Alan S. Perelson2

1UMR-0738, INSERM, Paros, France, 2Theoretical Biology and Biophysics, Los Alamos National Laboratory, Los Alamos, NM, United States, 3The Johns Hopkins University, Baltimore, MD, United States, 4Center for Biostatistics, Harvard School of Public Health, Boston, MA, United States, 5Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, United States, 6School of Medicine, University of California, San Diego, San Diego, CA, United States, 7School of Medicine, University of Pittsburgh, Pittsburgh, PA, United States, 8Brigham and Women’s Hospital, Boston, MA, United States

Background: Viral dynamics analyses have improved our understanding of HIV infection, revealing the timing and rates of important processes in the viral replication cycle. Here we analyzed the early kinetics observed with raltegravir-based treatment to gain new insights into the kinetics of viral decline.

Methodology: We analyzed data from 11 HIV-1 infected subjects enrolled in an intensive viral dynamics substudy (A5249s) of ACTG trial A5248 in treatment-naive subjects initiating treatment with raltegravir (RAL 400mg BID) and emtricitabine (FTC 200mg QD)/tenofovir disoproxil fumarate (TDF 300mg QD). After initiating treatment, subjects had plasma HIV-1 RNA measured at 0, 2, 4, 6, 12, 18, 24, 30, 36, 42, 48h and then on (or about) days 3, 4, 7, 10, and 14. To fit these data, we used a mathematical model of viral dynamics that distinguishes between infected cells with unintegrated HIV DNA and productively infected cells. Parameters were estimated using non-linear least square fitting.

Results: Whereas HIV RNA is usually described as declining linearly during the first two weeks of treatment (phase 1), our analysis revealed that RAL/FTC/TDF led to a biphasic decline of viral load, with a rapid first phase lasting for about 5 days, followed by a second slower phase of viral decline. The new model attributes the first phase (phase 1a) to the rapid elimination of productively infected cells. The second phase (1b) had a slower slope of decline and reflects the loss of infected cells with non-integrated provirus due to both cell loss and integration of HIV DNA. The model describes the data well and we estimate the half-life of productively infected cells was ~17 h, in good agreement with previous estimates; and the half-life of infected cells that had completed reverse transcription but had not yet integrated HIV DNA was >4.3 days, and quite variable. Additional parameters could not be estimated precisely, but the data is consistent with the time for half of activated cells to transition between pre-integration to post-integration being between 2 h and 16 h and the efficacy of RAL in preventing HIV-1 integration being ~96%. Lastly, our model predicts that the higher the efficacy of the integrase inhibitor the larger the phase 1a viral decline.

Conclusions: Using viral kinetic analyses we characterized the determinants of HIV RNA decline in a RAL containing regimen and estimated the effectiveness of RAL (~96%). We found, as previously suggested for RAL monotherapy, that the first phase was composed of two subphases corresponding to the half-lives of infected cells with integrated proviruses (17 hours) and unintegrated HIV-1 DNA (>4.3 days).
302 Characterization of Functional Profile of HIV-Specific CD4+ T Cells in VISCONTI Group of Patients

Assia Samir1, Charline Bacchus2, Laurent Hocqueloux2, Asier Saez-Cirion3, Amandine Emarré4, Christine Rouzioux4, Brigitte Autran5, and VISCONTI ANRS Study

1Immunology, UPDC Univ Paris O6, UMR-S945, Laboratory Immunity and Infection. Inserm, U945, Laboratory Immunity and Infection, Paris, F-75013, France, Paris, France, 2Immunology, Infectious and Tropical Diseases Department, Regional Hospital Center, Orleans, France, Orléans, France, 3Immunology, Institut Pasteur, Unité de Régulation des Infections Rétrovirales, Paris, France, Paris, France, 4Virology, Virology Laboratory, René Descartes University, EA 3620, Necker Enfants-Malades Hospital, Paris, France

Background: The mechanisms underlying the exceptional control of HIV replication and reservoirs observed in Post Treatment Controllers (PTC) remain unknown. To further understand such control we evaluated the functional profile of HIV-specific CD4+ T cells of PTCs from the prospective VISCONTI study (Virological and Immunological Sustained CONTROL after Treatment Interruption).

Methodology: Ten VISCONTI patients defined as controlling HIV (<400cp/mL) for a median 89 [IQR:73-103] months long interruption of a median 3 [IQR:1.7-5.9] years long HAART initiated within 10 weeks post-infection. Multiparametric flow cytometry assessed HIV-specific CD4 T cells producing IFNγ, IL2, TNFα, MIP1β, or expressing CD40L after stimulation by HIV-p24 peptides pool or p24 recombinant protein. Results were compared to those from 10 control fully-suppressed treated patients (pts) under at least 5 years long HAART initiated within 10 weeks post-infection. Statistics were done using Mann-Whitney tests.

Results: Relatively high frequencies of CD4+ T cells against the HIV-p24 peptide pool and recombinant protein were found and did not significantly differ between both groups with median values of: 0.125% [0.03-0.49] and 0.12% [0.02-0.68], respectively in VISCONTI pts, and 0.195% [0.01-1.16] and 0.44% [0.1-1.44] in control treated pts, though lower in the VISCONTI pts. In both groups, CD4+ T cells specific for HIV-p24 peptides produced more IL2 and MIP1β than IFN-γ while CD4+ T cells specific for the p24 recombinant protein were more polyfunctional, producing IL2, IFNy and MIP1β and expressing CD40L. Polyfunctional CD4 T cells directed against HIV p24 pool and p24 recombinant protein can be detected in both groups. Nevertheless in both groups specific CD4+ T cells expressed 1 to 4 functions with 29%, 37% 20% and 6% vs 55%, 13%, 14% and 1% against the p24 recombinant protein in Visconti vs controls pts. VISCONTI pts CD4 T cells against HIV p24 peptides produced significantly at least 2 functions than control treated pts (p=0.029).

Conclusions: The major virus control observed in PTC from the VISCONTI study is associated with relatively high frequencies of multi-functional HIV-specific CD4+ T cells. The 3 years long HAART regimen introduced early after infection might have preserved those HIV-specific cells which might participate in the post-treatment control of HIV.

303 Immune Activation and Defective pTFHs Are Associated With Impaired Immunity in Aging HIV+ Persons

Varghese K. George1, Suresh Pallikkuth1, Anita Parmigiani2, Maria L. Alcaide3, Margaret Fischl4, Savita Pahwa1

1Microbiology and Immunology, University of Miami, Miami, FL, United States, 2Human & Molecular Genetics, Virginia Commonwealth University, Richmond, VA, United States

Background: With improved antiretroviral treatment (ART) and increasing survival, the aging HIV infected population is rising. HIV infection and aging are independently associated with waning immunity including poor vaccine induced antibody responses, but the combination of HIV and aging needs further investigation.

Methodology: This study represents initial observations from a larger ongoing study in young (Y) and old (O) people in the presence (+) or absence (-) of HIV infection. Four groups n=12 each, O+ median age (Δ) 65yr; O- Δ 63yr; Y+ Δ 37yr, and Y- Δ 33yr were investigated. HIV+ were well controlled on ART with<48 HIV RNA copies/ml and mean±SD CD4 counts (cells/mm³) of 602.7±273.6 (O+) and 654.3±313.8 (Y+). Investigations included Hemagglutination inhibition (HAI) titers at pre- (T0) and 4 weeks post (T2) seasonal 2011-2012 influenza vaccination, immune activation (IA), and Immunologic analysis of peripheral T follicular helper cells (pTFH) and B cells. Differences between groups were analyzed by Student t-test and correlation between variables was determined by Pearson correlation and linear regression analysis.

Results: At T0, seroprotection [HAI titers ≥1:40] was less frequent in Old (O+ 33%, O- 25%) compared to Young (Y+ 75% and Y- 91.6%). At T2, a 4-fold increase in HAI titers was noted in Y+ [peak mean±SD titer, 246±337] but only in 50% of each of the other groups, with O+ exhibiting lowest peak titer (81±61). At T0, the O groups compared to Y had higher CD4 IA (CD38+HLADR+) and lower frequencies of pTFH (CD4+CD45RO+CXCR5+) with highest and lowest values respectively noted in O+. Following vaccination, HAI titers at T2 correlated with pTFH changes (expansion, upregulation of ICOS expression and intracellular IL21) and memory B cell changes (expansion, upregulation of IL21R and increases in H1N1 specific Ab responses in Elispot assay). The magnitude of these responses was in the order Y+>Y->O+>O-.

CD4 T cell IA at T0 was negatively correlated with HAI titers at T2. In 5 day PBMC cultures, addition of exogenous IL-21 augmented expansion of pTFH and ICOS expression in all four groups, and H1N1 specific Ab responses in ELISPOT assay were augmented in all except the O+ group.

Conclusions: Aging and HIV infection were independently associated with lower pTFH defects that contribute to B cell impairment, but the presence of HIV infection and aging together exhibited the worst immune profile, with highest underlying IA and poorest serologic response following influenza vaccination. Supplementation of IL-21 ex-vivo was partially restorative of the observed immune defects with better effects noted in HIV+ young than in HIV+ old, indicating the need for additional investigations and measures e.g. targeting immune activation in the HIV+ aging population.
**304 Fresh Cohort: Acute HIV-1 Infection in Cohort of High Risk HIV Negative Women in KZN, South Africa**

Krista Dong1,2, Amber Moodley1, Thumbi Ndungu1,2, Bruce Walker1,4

1Ragon Institute, Massachusetts General Hospital, Boston, MA, United States, 2Harvard Medical School, Boston, MA, United States, 3University of KwaZulu-Natal, Durban, South Africa, 4The Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States

**Background:** The HIV epidemic in KZN South Africa continues unabated amongst young at risk women. Seroprevalence data collected in 2009 at an antenatal clinic in the Umlazi KZN showed that 2 of 3 women become HIV-infected by 22 years of age. While ART availability in SA has increased steadily since launch of treatment in 2004 the magnitude of the epidemic underscores the need for a vaccine. Key to vaccine development is understanding factors that influence HIV disease progression. Characterization of immune responses in both the peripheral circulation and the female genital tract, the site of most common exposure, just prior to and in the earliest stages of acute infection may offer valuable insights.

**Methodology:** The study launched in December 2013, enrolling 30 women per month to create a cohort of 300 HIV-negatives aged 18 to 23 years to be followed for 24mo. Monitoring occurs twice weekly to check HIV-1 RNA PCR by finger prick during year 1, then 3-monthly during year 2. Blood collection and pelvic examination are performed every 3mo for 24mo for collection of PBMCs and mucosal tissue via cervical and vaginal swab, cervical cytobrush and cervicovaginal lavage . To support study retention participants are concurrently enrolled in 1-year life-skills poverty alleviation program, which meets on the same days as scheduled study follow-up.

**Results:** In September 2013 at 9mo after launch, 410 women have been screened and 288 found eligible. 205 are enrolled and in active follow-up; 6 identified with acute HIV-1 infection. 5 of 6 experienced flu-like symptoms consistent with acute viral syndrome around the time of infection. First +RNA PCR occurred after 16w of monitoring (4.5 to 44w) with initial VL of 34,616 copies/mL (160 - 120,000). Peak viremia was 28.5mil copies/mL (11-57) occurring at 7.6 days (7-11) after initial +RNA PCR. CD4 nadir of 299 mm-3 (217 - 506) occurred at 13d (3-24). Seroconversion by HIV rapid occurred at 16.8 days (14 - 21d) after +RNA PCR. 4 of 4 screened were found to have an STI at the time of acute infection. Seroconversion rate was estimated to be 7.71 (95% CI: 2.50-18.0) per 100 person-years.

**Conclusions:** Frequent monitoring of a cohort of high-risk women in KZN, SA enables identification of acute HIV-1 infection. Peak viremia is rapid, occurring within 7 days of initial +PCR. CD4 drops below 350 within 2w of +PCR, but rebounds. Combining a life-skills/empowerment intervention may increase study retention and compliance of high risk individuals expected to comply with frequent study visits.

---

**305 Vitamin D Significantly Changes the Immune Transcriptome and Augments CD4 Recall Responses in HIV**

Raskit Lachmann1, Margaret-Anne Bevan1, Sangmi Kim2, Nishma Patel1, Riddhima Banga1, Nagasuma Chandra1, Sudha Rao3, Catherine Hawrylowicz1, Annapurna Vyakarnam1, Barry Peters1

1Infectious Diseases, Kings College London, London, United Kingdom, 2GU Medicine and HIV, Guys and St Thomas’ Hospital Trust, London, United Kingdom, 3Indian Institute of Science, Bangalore, India, 4Genotypic Technology Limited, Bangalore, India, 5Division of Asthma, Allergy & Lung Biology, Kings College London, London, United Kingdom

**Background:** In vitro studies, including our laboratory, highlight the active metabolite of Vitamin D, Calcitriol, to have pleiotropic effects on innate and adaptive immunity. More recently, in vivo Vitamin D supplementation showed beneficial effects by promoting resolution of inflammation. HIV progression, which is associated with excessive immune activation and impaired T-cell immunity, is also associated with low serum vitamin D level although biological plausibility and causality have yet to be established. This study was therefore designed to assess the impact of Vitamin D supplementation on T-cell function in both HAART treated and treatment naïve HIV+ subjects.

**Methodology:** This prospective controlled study enrolled 28 subjects with low plasma vitamin D (Vit D) (<20ng/l, 50micromol/l) comprising 17 HIV+ patients (11 on HAART, 6 treatment naïve) and 11 healthy controls. A single dose of 200,000 IU oral cholecalciferol was administered. Blood samples were
analysed at baseline and one month. Advanced multi-colour flow cytometry was used to assess T-cell signalling, T cell effector responses, and markers of T-cell activation and homeostasis. In addition the whole blood transcriptome was analysed along with the primary Vitamin D receptor, VDR.

**Results:** Plasma Vit D levels were restored to normal at one month. The following statistically significant results were found: CD4 T-cell responses to CMV and SEB were markedly augmented in HAART+ subjects and similarly HIV-specific responses in HAART Naive subjects. Specifically MIP1β+; CD4 T-cell frequency increased in HAART+ subjects, concomitant with an increase in plasma MIP1β+, which correlated with plasma Vit D levels. An associated increase in prominal T-cell pERK mobilisation following PMA stimulation was noted. T-cell CD38 expression was downregulated only in HAART+ subjects; however no significant changes to T-cell CD39 or Treg and IL-17 numbers were noted. These specific changes to the T cell compartment were associated with changes to some 250 genes at the whole blood level in HAART naive and healthy controls. However, 10-fold fewer genes were altered in HAART+ subjects associated with significantly lower basal VDR expression. Pathways impacting T-cell function were altered in all three groups but a common gene signature spanning all three groups was not identified.

**Conclusions:** Vit D therapy may be a useful adjunct to HAART therapy in HIV infection by improving the quality of the T-cell response. The potential therapeutic benefit of this cheap, safe, easily administered therapy on slowing progression and reducing mortality in HIV merits testing in adequately powered clinical trials.

### 306 Impact of Methamphetamine Use On Immunologic and Virologic Markers During Suppressing ART

**Marta Massanella1, Sara Gianella1, Douglas D. Richman1, 2, Susan J. Little1, Constance B. Benson1, Eric S. Daar1, Michael D. Dube1, Richard H. Haubrich1, Davey M. Smith1, 3, Sheldon R. Morris1, the CCTG 592 Team**

1University of California San Diego, La Jolla, CA, United States, 2Veterans Affairs San Diego Healthcare System, La Jolla, CA, United States, 3Los Angeles Biomedical Research Institute, Torrance, CA, United States, 4University of Southern California Keck School of Medicine, Los Angeles, CA, United States, 5Veterans Affairs San Diego Healthcare System, La jolla, CA, United States

**Background:** Methamphetamine (meth) is a widely used recreational drug in North America, especially among HIV-infected men who have sex with men (MSM), and is associated with worse health outcomes in HIV infected persons.

**Methodology:** Fifty HIV-infected MSM on long-term antiretroviral therapy (ART) (median 3.8 years) with plasma HIV RNA <50 copies/ml and who were enrolled in a prospective clinical trial to reduce sexually transmitted infections were studied. Meth and other drug use in the past month were assessed at baseline with a self-administered internet-based survey along with other risk behaviors. Levels of immune activation (CD45RA-CD38+) and proliferation (Ki67+) of CD4+ and CD8+ T-cells subsets were determined from frozen peripheral blood mononuclear cells (PBMC) by multicolor flow-cytometry. Total HIV DNA (pol), 2-long terminal repeat (2-LTR), and cellular HIV RNA (unspliced and multiply-spliced encoding for tat/rev) were measured in PBMC by droplet digital PCR. Using non-parametric statistics, we investigated associations between recent use of meth with immune activation and proliferation of subsets of CD4+ and CD8+ T-cells in blood, CD4 count, time on ART, and with levels of HIV DNA and cellular HIV RNA.

**Results:** Twelve of 50 (24%) MSM reported meth use in the past month. Meth use was significantly associated with higher levels of immune activation (CD45RA-CD38+) and proliferation (Ki67+) of total CD4+ T-cells (both P<0.05), and with higher levels of proliferating CD8+ T-cells (P<0.01), in each analyzed subset (i.e. naive, central memory, transitional memory, effector memory CD8+ T-cells). Recent meth use was also associated with a trend towards higher levels of proviral HIV DNA reservoir (median of 2.09 vs. 1.83 log10 copies/million CD4+ T-cells, P=0.09) and higher levels of multiply-spliced cellular HIV RNA transcripts compared to those not using meth (P=0.06). Use of other drugs (cannabis, cocaine, other ‘club’ drugs, alcohol), CD4 counts and time on ART were not associated with any differences in immunologic or virologic markers. Self-reported adherence to ART was not significantly different between meth users and non-meth users (P=1.0).

**Conclusions:** Self-reported meth use by HIV-infected MSM on long-term ART with fully suppressed plasma HIV RNA levels was uniquely associated with increased T-cell immune activation and proliferation, both of which could explain meth-related co-morbidities. Meth users might also have a greater HIV DNA reservoir and residual HIV RNA replication than non-meth users, but this observation and the underlying immunomodulatory mechanisms of meth in HIV-suppressed individuals need to be confirmed in a longitudinal study including a larger population.

### 307 Vitamin D-Receptor Gene Polymorphisms: Association With Virologic Failure and Mortality

**Simbarashe Takuva1, 2, Lynne McNamara1, Tobias Chirwa2, Jan Sanne1, Adrian R. Martineau2, Patrick A. MacPhail2**

1Centre for HIV and STIs, National Institute for Communicable Diseases, NIHS, Johannesburg, South Africa, 2Department of Internal Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, 3Clinical HIV Research Unit, Department of Internal Medicine, University of the Witwatersrand, Johannesburg, South Africa, 4School of Public Health, University of the Witwatersrand, Johannesburg, South Africa, 5Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom

**Background:** Host genetic factors play an important role in disease. Due to its extensive role in the immune system, vitamin D may have a potential role in altering HIV disease progression. Vitamin D actions are mediated by the vitamin D receptor (VDR). Polymorphic variations exist in the VDR gene, each of which may have different significance in disease susceptibility and progression. We set out to examine if VDR gene variations, corresponding to Apa1, Bsm1, Fok1 and Taq1 polymorphisms were associated with HIV disease progression.

**Methodology:** We analyzed cohort data for 142 HIV-infected patients initiating ART in South Africa between November 2008-March 2009. We defined disease progression as: 1) failure to achieve viral suppression (viral load <50copies/ml) within the first 12-months of ART and; 2) mortality during follow-up. Genomic DNA was extracted from whole blood using standard methods and analysed for polymorphisms in the VDR gene. Cox proportional hazards models were used to estimate the association of genotype status (Hazard Ratios (HR) and 95%CI) with disease progression. Models were adjusted for age, gender, BMI, WHO stage, CD4 count, haemoglobin level, employment status and ART regimen.
Consistent with the hypothesis that statin use may contribute to accelerated immune reconstitution, we observed a significant increase in CD4 gains in patients exposed to statins compared to those who were not exposed. The contribution of statins to CD4 gains was evident across all quartiles of CD4 increase, with the magnitude of effect being highest in the lowest quartile. The contribution of statins to increased CD4 gains was also observed in the subgroup of patients exposed to HAART, further suggesting a potential role for statins in enhancing immune reconstitution in this population. These findings suggest that statin use may be a modifiable factor that could be targeted in interventions aimed at improving immune reconstitution and achieving faster viral suppression in HIV-infected patients.

Results: Statin use was associated with greater CD4 gains, faster immune reconstitution, and faster time to viral suppression in HIV-infected patients. The contribution of statin use to CD4 gains was significant across all quartiles of CD4 increase, with the magnitude of effect being highest in the lowest quartile. The contribution of statins to increased CD4 gains was also observed in the subgroup of patients exposed to HAART, further suggesting a potential role for statins in enhancing immune reconstitution in this population. These findings suggest that statin use may be a modifiable factor that could be targeted in interventions aimed at improving immune reconstitution and achieving faster viral suppression in HIV-infected patients.
**309** Maraviroc Intensification in HIV-Infected Patients Induces Increased CCR5 Expression On T Cells  
Assia Samiri, Gael Mouliol, Christina Psomas, Melanie Lavenu, Selma Trabelsi, Lise Cuzin, Pierre Corbeau, Brigitte Autran, Philippe Flandre  
1Immunology, UPMC Univ Paris 06, UMR-S945, Laboratory Immunity and Infection, INSERM, U945, Laboratory Immunity and Infection, Paris, France; 2Immunology, Infectious Diseases Department, University Hospital, Institute for Human Genetics, CNRS UPR1142, Montpellier, France; 3Immunology, INSERM U 943 and University Pierre and Marie Curie, UMR 843, Paris, France; 4Immunology, Infectious Diseases Department, University Hospital, Lille, Institute for Human Genetics, CNRS UPR1142, Montpellier, France

**Background:** Our group showed that Maraviroc (MVC) intensification over 24 weeks (W) in immunological non responders over the last two years (CD4 < 350 cells/mm³, CD4 slope < 50 cells/mm³/year and HIV-RNA < 50 copies/ml) enhanced CD4 cell slopes and significantly decreased CD8+ T cell activation. We analyzed whether these effects were associated with modulation of CCR5 expression on various T cell subsets, frequencies of virus-specific T cells and levels of CCR5 ligands.

**Methodology:** 31 patients were monitored at baseline, after 24W of MVC intensification and at W28 (4W post-intensification). We evaluated CCR5 modulation on different T-cell subsets (Naïve (N), Central-Memory (CM), Effector-Memory (EM), Effector (E) and on CD4 T cells expressing CXCR3, CCR4 or CCR6, as well as on activated CD4+ and CD8+ T cells in parallel to plasma CCR5 ligands (MIP-1A, MIP-1B and RANTES) levels. T cells specific for HIV-1 gag and CMV antigens were quantified using IFN-γ ELISpot assay.

**Results:** During MVC intensification, a decrease in activated CD8+DR+CD38+ T cells is observed (-26%; p=0.001). We also observe a significant increase of CCR5 on CD4+ (+6%; p < 0.001) and CD8+ T cells (+15%; p < 0.001), mainly on CD8+ TEM (+14%; p = 0.003) and on activated CD8+DR+CD38+ T cells (+10%; p=0.00014). MVC intensification also resulted in significant increase in CCR5 expression on CD4+CXCR3-CCR4+CCR6+ T cells defining Th17 cells (+4%; p=0.003). This increased CCR5 expression paralleled an increase in MIP-1B plasma levels (+57pp/ml; p=<0.001). At W28, 4 weeks after stopping MVC both CCR5 expression and MIP-1B levels were reversed. No significant changes were observed in frequencies of CMV- or HIV-specific T cells.

**Conclusions:** The blockade of CCR5 receptor-ligand interaction by MVC not only reduced CD8+ T-cell activation but also increased CCR5 expression mainly on effector-memory and activated T cells, paralleling the increase in plasma levels of MIP-1B the CCR5 ligand. These changes during MVC intensification might reflect a preferential decrease of activated T cells that do not display CCR5 and the redistribution of CCR5+ activated differentiated T cells in association with the positive effect on CD4 counts in immunological non responders.

**237** CD161+Vα7.2+IL18R+ MAIT Cells Are Reduced in HIV Infection Regardless of the Disease Status  
Johanna M. Eberhard, Philip Hartjen, Ashwin Balagopala, Clara Lehmann, Dominik Ebert, Ilona Töth, Silke Kummer, Reinhold E. Schmidt, Jan van Lunzen, Julian Schalke zur Wicsch  
1Infectious Diseases Unit, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 2Department of Oral and Maxillofacial Surgery, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 3Department of Medicine, Johns Hopkins University, Baltimore, MD, United States; 4Department of Medicine, University Medical School, Cologne, Germany; 5Clinic for Immunology and Rheumatology, Hannover Medical School, Hanover, Germany

**Background:** Mucosal-associated invariant T (MAIT) cells are characterized by the combined expression of the semi-invariant TCR Vα7.2, the lectin receptor CD161 and the IL18 receptor. They play an important role in the antibacterial host defense of the gut. CD161+ MAIT cells vanish almost completely from the bloodstream in HIV-infected patients and cannot be restored by antiretroviral therapy. To date, the mechanisms causing this HIV-associated reduction of MAIT cells are not well understood and it is not known whether the magnitude of the reduction depends on the disease status. Thus, we aimed to comprehensively characterize a large cohort of HIV patients including patients with slow disease progression and elite controllers and to explore the mechanisms that lead to the loss of MAIT cells in HIV infected patients.

**Methodology:** PBMC and lymph node samples from 60 patients with different disease status, including patients with a high viral load (high VL), patients under antiretroviral therapy (ART), elite controllers (EC) and long term non-progressors (LTNP), were analyzed by multicolor flow cytometry. MAIT cells were analyzed for their activation level and migration pattern ex vivo and after in vitro stimulation with different cytokines (IL-7, IL-18, IL-12) and fixed bacteria (E.coli). Furthermore, their capacity to produce cytokines (IL-17, IL-22, IFN-γ) was determined by intracellular cytokine staining. Plasma IL18-, sCD14- and sCD163 levels were determined by ELISA, to reveal further associations with disease progression.

**Results:** We demonstrate an irreversible reduction of MAIT cells during HIV infection regardless of the patients disease status in the blood (p< 0.05 for all patient groups vs. healthy controls) as well as in lymph nodal tissue. Elevated levels of IL18 and soluble CD14/CD163 are detectable in the plasma of HIV patients, which was paralleled by a loss of CD161+ MAIT cells and increased activation and exhaustion status as well as upregulation of the gut-homing markers CCR9 and beta7 integrin. Analysis of the expression of CD161 and IL18R on TCR Vα7.2+ T cells revealed a phenotypic shift with a loss of these markers accompanied by a functional disturbance involving a reduced capacity to produce IL17. This phenotypic shift can be replicated by in vitro stimulation of MAIT cells with IL18 and IL12 and fixed E.coli.

**Conclusions:** MAIT cells are drastically reduced in the peripheral blood of all HIV infected patient groups regardless of the disease status. We propose a multifractal model to explain loss of MAIT cells during HIV infection that involves activation induced cell death, a phenotypic shift and an increased tissue migration.
238  HIV-1 Alters Plasmacytoid Dendritic Cell Phenotype and Function by Modulating ILT Receptors

Adel Benlahrech, Amina Yasin, Peter Kelleher, Nasrina Imani, Steven Patterson
Immunology, Imperial College London, London, United Kingdom

Background: Dendritic cells (DC), the antigen presenting cells that initiate or shut down adaptive immune responses, exist as two main subsets in peripheral blood namely: myeloid (m)DC, the precursors of tissue DC; and plasmacytoid (p)DC, the main producers of IFN-alpha. Both populations are reduced in HIV-1 infection and their dysfunction has been implicated in HIV-1 immunopathogenesis. The aim of this study was to characterise the impact of HIV-1 on the immunoregulatory functions of peripheral DC, in particular the IFN-alpha blocking immunoglobulin like transcript (ILT)-7 and the T-regulatory (T-reg) inducing receptors, ILT-3 and ILT-4.

Methodology: Peripheral blood was collected from three cohorts of patients: healthy controls (n=11), therapy naïve patients (n=11), and treated patients (n=11). Cell surface expression of ILT-3, -4, and -7 by pDC and mDC was determined by flow cytometry. For functional studies, pDC and mDC were isolated from healthy donors using magnetically-labelled beads and treated with live HIV-1 IIIB, HIV-1 BAL, or influenza virus with or without toll like receptor-7 ligand (R848). The ability of DC to stimulate T-reg was determined using co-culture assays followed by intracellular staining for FoxP3.

Results: Myeloid DC from HIV-1+ patients exhibited normal levels of ILT-3, -4, and -7 regardless of therapy status, whilst pDC from viremic patients expressed significantly higher levels of ILT-3 and lower levels of ILT-7 in comparison to healthy donors and treated patients. Activation of purified pDC with R848 in vitro resulted in a significant reduction in ILT-3 and ILT-4 expression compared to unstimulated pDC. Whilst, treatment of pDC with HIV-1 IIIB failed to reduce ILT-3 levels and resulted in moderate down-modulation of ILT-4, which remained statistically higher than that observed with R848. Co-treatment of pDC with R848 and HIV-1 IIIB, or HIV-1 BAL resulted in reversal of R848-mediated reduction of ILT-3 expression. Functionality of ILT-3 was further confirmed by its cross-linking on pDC that resulted in increased levels of FoxP3 + T-regs.

Conclusions: Elevated proportions of circulating pDC displaying higher levels of T-reg inducing molecules with a predisposition to chronically secrete IFN-alpha through down-regulation of ILT-7 characterise untreated HIV-1 infection. HIV-1 may subvert adaptive immunity through its ability to inhibit full maturation of pDC by blocking activation-induced down-regulation of ILT-3 and ILT-4, potentially leading to raised T-reg activity.

239  Innate Immune Reconstitution With Viral Suppression in HIV-1 Infection

Eileen Scully1, 2, Ainsley Lockhart1, Chelsey Musante1, JJ Chang1, Molly Amero1, Eric Rosenberg1, Ronald J. Bosch1, Marcus Attfield1, 5
1Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States, 2Division of Infectious Disease, Brigham and Women’s Hospital, Boston, MA, United States, 3Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, United States, 4Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, United States, 5Heinrich-Pette-Institut, Leibniz Institute for Experimental Virology, Hamburg, Germany

Background: HIV-1 infection leads to both marked immunodeficiency and to dysregulated immune activation and inflammation. Given the broad nature of immune dysfunction and pathogen susceptibility, we hypothesized that HIV-1 viremia would alter innate immune responses, the fundamental mediators of pathogen recognition. Using longitudinal samples collected before and after initiation of antiretroviral therapy (ART), we tested the capacity of myeloid dendritic cells (mDCs) and monocytes to respond to a panel of innate stimuli. We combined these direct measures of ex vivo cellular responses with measures of T cell activation and plasma inflammatory markers to elucidate the inflammatory environment and viral parameters associated with impaired innate immune function.

Methodology: Pre and multiple post-ART peripheral blood mononuclear cell (PBMC) samples were selected for 8 subjects identified in early HIV-1 infection. Cells were stimulated with heat killed Listeria monocytogenes (HKLM, TLR2 agonist), lipopolysaccharide (LPS, TLR4 agonist), or N-muramyl glycopeptide (NOD agonist), and stained for intracellular cytokine production (TNF-alpha, IL-1beta, IL-23) after 20 hours of culture. Matched plasma samples were tested for levels of LPS, soluble CD163 and CD14, and a panel of inflammatory cytokines.

Results: Declining viral load was correlated with increasing magnitude of monocyte and mDC response to LPS stimulation (% TNF alpha+; repeated measures analysis: p<0.01 for both cell types, rank correlations = -0.57 and -0.54). Responses also negatively correlated with CD8 T cell activation level (p<0.01) but were not related to CD4 count. Exploratory analyses indicate similar associations of declining viral load with increasing TNF alpha and IL-1beta responses to TLR2 agonists, and IL-1beta responses to NOD stimulation. Suppression of HIV-1 was associated with an increase in polyfunctional responses by monocytes and mDCs to LPS, NOD, and HKLM. Plasma viral load had the strongest association to innate cell function, although paired analysis of plasma samples revealed trends towards association between increasing magnitude of innate response and declining sCD163, sCD14 and LPS.

Conclusions: Suppression of HIV-1 viral load with ART was associated with increased innate immune cell responsiveness in longitudinal samples. Depressed innate immune function was most strongly tied to high viral load and T cell activation, possibly suggesting an innate exhaustion in HIV-1 viremia parallel to that seen in adaptive immunity. Identifying the drivers of innate immune dysfunction offers important insights into the determinants of HIV-1-associated immune deficiency and may help to identify patients at risk for immune reconstitution inflammatory syndrome following ART.
CD4:CD8 Ratio Remains Significantly Depressed Despite Viral Suppression With Effective ART

Brinda Emu1, Jeffrey Martin2, Douglas Nixon4, Steven G. Deeks3, Joseph M. McCune2
1Yale University, New Haven, CT, United States, 2University of California, San Francisco, San Francisco, CA, United States

Background: Inverted CD4:CD8 ratio is known to be indicative of advanced, untreated HIV infection. In the HIV-uninfected population, a low CD4:CD8 ratio has also been associated with near-term mortality in the elderly. This study aimed to characterize the CD4:CD8 ratio in untreated and treated HIV-infected, and to determine the relative dynamics of changes in each population over time during effective ART. CD4:CD8 ratio in HIV-infected individuals on effective antiretroviral (ARV) regimens.

Methodology: CD4:CD8 ratio was evaluated in HIV-infected subjects with viral loads >10,000 copies/μl (“non-controllers”, n=42), those with undetectable viral loads on ART (“ART-suppressed”, n=55), and HIV-uninfected subjects (n=22) from a longitudinal cohort study in San Francisco (SCOPE). In addition, CD4:CD8 ratio, and T cell phenotypes were evaluated in 25 non-controllers, 18 ART-suppressed, and 7 HIV-uninfected subjects.

Results: CD4:CD8 ratio in non-controllers, ART suppressed, and HIV-uninfected subjects was 0.25, 0.48, and 1.95 respectively (p<0.0001 for all comparisons). The increased ratio in ART-suppressed compared to non-controllers was driven by an increase of CD4+ T cells, with limited differences in the expanded CD8+ T cell population. We also studied longitudinal changes in ratio in a subset of 15 individuals who had been on effective therapy for for a median of 3.7 years (1.0 - 6.9) and who had a median CD4+ T cell count of 482 (range 300-1079) and a ratio of 0.44 (range 0.21-1.52). With additional time on ART (median of 3.1yrs, range 1.4-4.3 yrs), total CD4+ T cell counts increased by 101 cells/mcl (p=0.02) while CD8+ T cells generally remained stable (p=0.22), resulting in an overall increase in CD4:CD8 ratio from 0.44 to 0.60 (p=0.02). However, the overall gains in CD4:CD8 ratio was driven by only a few individuals (five of fifteen), with the majority of individuals showing minimal change in the ratio during this time.

Conclusions: Untreated HIV infection is associated with a low CD4:CD8 ratio. Effective therapy improves the ratio, but this improvement is primarily caused by increases in CD4+ T cell counts. Increases in the ratio are largely due to increased CD4+ T cells, with a persistently expanded CD8+ T cells limiting further normalization of the ratio. Only a minority of individuals demonstrated any further gains in CD4:CD8 ratio with prolonged ARV therapy. A low CD4:CD8 ratio is a biomarker of poor clinical outcomes in the elderly non-HIV infected population, but requires further studies of clinical correlation in HIV-infected individuals.
**Poster Abstracts**

**242 A Low CD4/CD8 Ratio During Effective ART Predicts Immunosenescence and Morbidity/Mortality**

Sergio Serrano-Villar, Talia Sainz, Sulggi A. Lee, Peter W. Hunt, Elizabeth Sinclair, Jeffrey N. Martin, Joseph M. McCune, Steven G. Deeks

1Infectious Diseases, University Hospital Ramón y Cajal, Madrid, Spain; 2Infectious Diseases, University Hospital Gregorio Marañón, Madrid, Spain; 3University of California San Francisco, San Francisco, CA, United States; 4University of California Davis, Davis, CA, United States

**Background:** A low CD4/CD8 ratio in elderly HIV-uninfected adults is associated with increased morbidity and mortality. A subset of HIV-infected adults receiving ART fails to normalize this ratio, even after a normal peripheral CD4 count is obtained. The immunologic and clinical characteristics of this clinical phenotype remain undefined.

**Methodology:** We evaluated the associations of the CD4/CD8 ratio with 1) maturational subsets and markers of T-cell activation (%HLADR+CD38+), %EMT+ CD4+ CD8+ T-cells (all P<0.05), while those with a normal CD4/CD8 ratio (≥4th Quartile, 1.0) had normal levels. The CD4/CD8 ratio correlated substantially with sCD14, hs-CRP, IL-6 and the KT ratio-a marker of indoleamine-dioxygenase-1 induction-with only the KT ratio was significantly correlated in the subgroup with CD4≤500 cells/mm3 (Rho=-0.29, P=0.041). The peripheral CD4/CD8 ratio was similar to the ratio in gut mucosa (Rho=0.68, P<0.001) but not in lymph nodes. In a longitudinal study, early ART initiators had a faster CD4/CD8 ratio increase than later ART initiators (Rho=0.44 vs. +0.25, respectively, P<0.001). After a median of 3 years of ART, early ART initiators had more CD4/CD8 ratio normalization (OR, 3.6; 95% CI, 1.2, 10.8). After controlling for age, gender, ART duration, nadir and CD4 count, each 10% decrease in the CD4/CD8 ratio was associated with 48% higher odds of serious non-AIDS events (P=0.045) and 13% higher odds of mortality (P=0.01).

**Conclusions:** A persistently low CD4/CD8 ratio during otherwise effective ART is associated with increased innate and adaptive immune activation, an immunosenescent phenotype, and higher risk of morbidity/mortality. This ratio may prove useful in monitoring response to ART and could identify a unique subset of individuals needed of novel therapeutic interventions.

**243 CMV and HIV: A Double Hit On the CD4/CD8 Ratio**

Talia Sainz, Sergio Serrano-Villar, Sulggi A. Lee, Peter W. Hunt, Elizabeth Sinclair, Jeffrey N. Martin, Joseph M. McCune, Steven G. Deeks

1Molecular Immune Biology Laboratory, University Hospital Gregorio Marañón, Madrid, Spain; 2Molecular Immune Biology Laboratory, University Hospital Ramón y Cajal, Madrid, Spain; 3University of California San Francisco, San Francisco, CA, United States

**Background:** Advanced age is associated with a number of immunologic abnormalities, including a low CD4/CD8 ratio and increased frequency of terminally-differentiated CD8+ T cells (“immunosenescence”). CMV infection significantly contributes to this immunosenescent phenotype. Although HIV infection is associated with high levels of CMV-related inflammatory responses and many of the classic markers of immunosenescence, the relative contribution of CMV and HIV to the development of T cell abnormalities during HIV disease is not known. We examined the impact of CMV and HIV on the CD4/CD8 ratio, which is one of the most validated markers of T-cell senescence.

**Methodology:** We analyzed 228 subjects, including 8 HIV-CMV-, 15 HIV-CMV+ and 205 HIV+CMV+ individuals [91 controllers (<1000 HIV RNA copies/mL), 91 ART-suppressed and 23 untreated]. We analyzed correlations between the CD4/CD8 ratio and CMV- and HIV-specific T cell responses [proportion of T cells expressing high levels of IFN-gamma, CD107-alpha, TNF-alpha and IL-2 after stimulation by CMV and HIV proteins (IE and pp65, and gag, respectively)].

**Results:** The CD4/CD8 ratio significantly changed across all subgroups, according to the different immunological background determined by HIV and CMV, as shown in the figure.

Among 228 individuals, high CMV-specific IFN-gamma production of CD8 T cells was associated with low CD4/CD8 ratio (Rho=-0.30, P<0.01). Similar associations were observed for CMV-specific CD107-alpha, IL-2, TNF-alpha and CD8 T-cell response (all P<0.05). The effect of CMV-specific T cell response on ratio was more consistent than the association with either absolute CD4 or CD8 T cell counts, and was consistent within both the HIV- and the HIV+ ART-suppressed groups (in ART-suppressed, for IFN-gamma CD8 T cell response, Rho=-0.24, P=0.01). The CD4/CD8 ratio was also lower across all groups in subjects with higher HIV-specific CD4 T-cell responses, being the strongest correlations with IFN-gamma (Rho=-0.25, P<0.001), IL-2 (Rho=-0.23, P=0.001) and TNF-alpha (Rho=-0.29, P<0.001) CD4 T-cell responses.

**Conclusions:** The specific inflammatory responses elicited by CMV and HIV are likely major drivers of a low CD4/CD8 ratio across the whole spectrum of HIV
Mucosal CD4 and TH17 Cells

Thursday March 6, 2014, 2:30–4:00 PM Exhibit Hall A

Conclusions:

in specific inhibition of IL-23 signalling. Expression of the IL-23 receptor protein IL23R was comparable between HIV-seronegative controls, untreated, and inability of HAART to restore Th17 frequency and function and the resulting persistent chronic immune activation observed in HIV-infected individuals. The CD4/CD8 ratio parallels well the progressive decline in immune competence determined by CMV and HIV, and might be considered in clinical settings as a surrogate marker of immunosenescence.

Severe Depletion of Lung CD4 T Cells During HIV Infection Impairs Alveolar Macrophage Function

Bjorn Corleis1, Maud Deruaz2, Mels N. Anahtar1, Gregory Olson1, Brittany Bowman1, Vladimir Vrbanac2, Andrew M. Tager1, Douglas S. Kwon1
1Ragon Institute of MGH, Harvard and MIT, Cambridge, MA, United States, 2Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States

Methodology:

To study HIV infection in the lung, we made use of a humanized mouse model. 7 weeks after HIV-1 challenge, bronchoalveolar lavage fluid (BALF) and lung tissue were harvested. Alterations in the frequency, phenotypes and gene transcription of human macrophages and T cells in the alveolar space and lung tissue of HIV infected animals were analyzed using FACS, luminex and immunohistochemistry. Results were confirmed in BALF samples obtained from HIV-infected and uninfected individuals and surgical excess lung tissue. Further, alveolar macrophages from HIV infected and uninfected subjects were isolated and changes in the transcriptional profile determined using RNAseq.

Results:

Prior to HIV infection, the majority of human CD4 and CD8 T cells in the lung and alveolar space were of an effector memory phenotype whereas the majority of blood T cells were naïve. Percentage of activated and CCR5+ CD4 T cells was significantly higher in the lung compared to PBMCs. HIV infection resulted in 3 fold higher depletion of CD4 T cells in lung tissue compared to blood whereas CD4 T cells in the alveolar space were almost completely depleted. Lung macrophage cell numbers were not altered after HIV infection however, CD40 expression was significantly reduced, which correlated with CD4 T cell depletion and decrease of soluble CD40L in BALF. Whole RNA sequencing analysis of human alveolar macrophages revealed over 160 genes differently expressed in macrophages isolated from HIV+ individuals compared to HIV negative control donors. Pathway analyses revealed significant down-regulation of pathways involved in pro-inflammatory cytokine responses and intracellular bacterial killing in the HIV+ individuals.

Conclusions:

Prior to HIV infection, CD4 T cells in the lung have a memory phenotype, are activated and express CCR5. Upon HIV infection CD4 T cell depletion in the lung is much more severe relative to blood leading to impairment of T cell help for alveolar macrophages and down-regulation of important intracellular macrophage defense mechanism against bacterial infections such as tuberculosis.

Impaired IL-23 Signalling and Th17 Dysfunction in HIV Infection

Jason R. Fernandes1, Ashok Kumar2, 3, Jonathan B. Angel1, 3
1Chronic Diseases, The Ottawa Hospital Research Institute, Ottawa, ON, Canada, 2Pathology, Children’s Hospital of Eastern Ontario Research Institute, Ottawa, ON, Canada, 3Faculty of Medicine, University of Ottawa, Ottawa, ON, Canada

Background:

Th17 cells maintain gut homeostasis by co-ordinating a variety of innate and adaptive immune responses. HIV infection causes a profound depletion of gut Th17 cells, contributing to loss of mucosal barrier function and microbial translocation, thus driving systemic immune activation. Despite normalisation of circulating CD4+ T cell counts with highly active antiretroviral therapy (HAART), Th17 frequency and function often remain impaired. The IL-12 family cytokine member IL-23 plays a crucial role in maintaining normal Th17 cell function. We hypothesize that HIV inhibits IL-23 signalling in Th17 cells, resulting in Th17 dysfunction.

Methodology:

Th17 cells were isolated from peripheral blood of HIV-seronegative donors by magnetic selection and infected with HIVCS204, a dual-tropic clinical isolate for 24 hours. Expression of IL-17 was examined by ELISA and flow cytometry. Levels of Th17-associated transcription factors STAT3 and retinoic acid orphan receptor C (RORC) mRNA expressed in response to IL-23 stimulation were quantified by qRT-PCR. Phosphorylation of STAT3, the primary transducer of IL-23 signalling, in response to IL-23 stimulation was assessed by flow cytometry. Th17 cells were then isolated from untreated and HAART-treated HIV-infected individuals, and STAT3 phosphorylation (pSTAT3) in response to IL-23 was examined. Expression of the IL-23 receptor protein IL-23R on Th17 cells was examined by flow cytometry.

Results:

In vitro HIV infection significantly inhibited IL-17 production in response to TCR and mitogen stimulation. In vitro HIV infection also significantly reduced IL-23-induced pSTAT3 and expression of STAT3 and RORC mRNA. Th17 cells isolated from untreated and HAART-treated HIV-infected individuals showed complete loss of IL-23 responsiveness. IL-6 induced pSTAT3 was unaffected by in vitro and in vivo infection, suggesting that HIV infection results in specific inhibition of IL-23 signalling. Expression of the IL-23 receptor protein IL-23R was comparable between HIV-seronegative controls, untreated, and HAART-treated HIV-infected individuals.

Conclusions:

These results demonstrate that in vitro and in vivo HIV infection results in impaired IL-23 signalling which is not reversed by HAART and is not a result from reduced receptor expression, demonstrating that HIV interferes with IL-23-activated signalling pathways. These findings may explain the inability of HAART to restore Th17 frequency and function and the resulting persistent chronic immune activation observed in HIV-infected individuals.
Th17 and Tregs at Early HIV Infection Influence Disease Progression and HIV Specific CD8+ Responses

Juliana Falivene1, Yanina A. Ghiglione1, Natalia L. Lauger1-2, María E. Socías1, María J. Ruiz2, Pedro Cahn2-3, Omar Sued2-3, Horacio Salomón1, Gabriela Turk1, María M. Gherardi1

1Instituto de Investigaciones Biomédicas en Retrovirus y SIDA, UBA-CONICET, Buenos Aires, Argentina, 2Hospital Juan A. Fernández, Unidad Enfermedades Infecciosas, Buenos Aires, Argentina, 3Fundación Huésped, Buenos Aires, Argentina

Background: Th17 and Treg subsets have been related to HIV/SIV disease progression. Their role and direct relation with specific HIV-adaptive T cells response during primary HIV infection (PHI) are unclear topics. Aim: To analyze the frequency and balance of Th17 and Treg subsets and the correlation with clinical parameters, immune activation and HIV-specific responses during early infection.

Methodology: PBMCs were obtained from 6 healthy donors (HDs) and 28 HIV infected subjects: 6 elite controllers (ECs), 5 chronics (Chs) and 17 PHIs (within 6 months post-infection (mpi)). Th17 and Treg cells (baseline and 12 mpi samples) were identified as CD3+/CD4+ IL-17+ or CD25+/FoxP3+ (respectively). Data was compared inter/intragroups and correlated to clinical parameters (viral load (VL), CD4 counts), CD4 + or CD8+ CD38+/HLA-DR+ activated T cells and HIV-specific CD8+ responses (specifically a viral inhibitory activity (VIA) assay and intracellular cytokine staining (ICS) for IFN-γ production and CD107a/b cytotoxicity markers) measured at baseline, 6 and 12 mpi, using parametric and nonparametric statistics.

Results: Th17 cells compared to HDs and ECs (p=0.006 and 0.021 respectively), among which frequencies were similar (median 0.14 vs 0.11 respectively). In PHI group, CD4 counts at 6 mpi directly correlated with baseline Th17 counts (p=0.048, r=0.5). Moreover, VL at 12 mpi inversely correlated with baseline % of Th17 (p=0.041, r=-0.596). Th17/Tregs ratio was higher for HDs compared to any HIV+ group (p<0.01), and within PHIs Th17/Tregs was directly associated with CD4 counts at 12 mpi (p=0.017, r=0.793). Significantly, Th17 and quality of HIV-specific CD8+ responses, previously observed to be protective, were directly associated: higher basal % of Th17 correlated with higher CD8+-mediated VIA at 12 mpi (p=0.004, r=0.829) and Th17 counts at 12 mpi also related with % of HIV CD8+/CD107a+b/IFN-gamma+ cells (p=0.024, r=0.847). Regarding immune activation, as expected HDs had the lowest and Chs the highest % of activated T cells compared to the other groups (p<0.05). Of note, in PHIs activation occurs rapidly after infection and normalizes at 12 mpi (p=0.004). Importantly, Th17/Tregs ratio of groups altogether, negatively correlated with activated CD8+ and CD4+ T cells (p<0.05), suggesting a proper balance is associated with a lower level of immune activation.

Conclusions: Results indicate that higher counts and frequency of Th17 and higher Th17/Tregs ratio at early stages of HIV infection associate with slower disease progression in terms of clinical parameters and immune activation. Importantly, preservation of Th17 subset associates with the capacity to exert protective HIV-specific CD8+ responses at later times post-infection.

Profound Lung CD4+ T-Cell Depletion in HIV-Associated Chronic Obstructive Pulmonary Disease

Lulía Popescu1, M. Bradley Drummond2, Lucio Gama2, Christian Merlo2, Robert Wise2, Janice Clements2, Gregory D. Kirk3, John F. McDyer4

1Medicine, University of Pittsburgh, Pittsburgh, PA, United States, 2Medicine, The Johns Hopkins University, Baltimore, MD, United States, 3School of Public Health, The Johns Hopkins University, Baltimore, MD, United States

Background: As overall survival improves, individuals with chronic HIV infection become susceptible to other chronic diseases. In this regard, select HIV-infected individuals develop accelerated chronic obstructive pulmonary disease (COPD). We hypothesized patients with HIV-associated COPD develop dysregulation of lung mucosal immunity associated to HIV-infected individuals without COPD.

Methodology: To test our hypothesis, we evaluated the clinical characteristics in 11 HIV+COPD+ versus 10 HIV+COPD- individuals from a prospectively followed inner city cohort, and performed phenotypic/functional T cell analysis using multi-parameter flow cytometric analysis. Consented subjects underwent bronchoalveolar lavage (BAL) to obtain lung mononuclear cells (LMNC) and same day blood draw for isolation of peripheral blood mononuclear cells (PBMC).

Results: HDs had lower % of Th17 cells compared to HDs and ECs (p=0.006 and 0.021 respectively), among which frequencies were similar (median 0.14 vs 0.11 respectively). In PHI group, CD4 counts at 6 mpi directly correlated with baseline Th17 counts (p=0.048, r=0.5). Moreover, VL at 12 mpi inversely correlated with baseline % of Th17 (p=0.041, r=-0.596). Th17/Tregs ratio was higher for HDs compared to any HIV+ group (p<0.01), and within PHIs Th17/Tregs was directly associated with CD4 counts at 12 mpi (p=0.017, r=0.793). Significantly, Th17 and quality of HIV-specific CD8+ responses, previously observed to be protective, were directly associated: higher basal % of Th17 correlated with higher CD8+-mediated VIA at 12 mpi (p=0.004, r=0.829) and Th17 counts at 12 mpi also related with % of HIV CD8+/CD107a+b/IFN-gamma+ cells (p=0.024, r=0.847). Regarding immune activation, as expected HDs had the lowest and Chs the highest % of activated T cells compared to the other groups (p<0.05). Of note, in PHIs activation occurs rapidly after infection and normalizes at 12 mpi (p=0.004). Importantly, Th17/Tregs ratio of groups altogether, negatively correlated with activated CD8+ and CD4+ T cells (p<0.05), suggesting a proper balance is associated with a lower level of immune activation.

Conclusions: Results indicate that higher counts and frequency of Th17 and higher Th17/Tregs ratio at early stages of HIV infection associate with slower disease progression in terms of clinical parameters and immune activation. Importantly, preservation of Th17 subset associates with the capacity to exert protective HIV-specific CD8+ responses at later times post-infection.
248  Site Specific HIV-Infection of Th17 Cells in the Human Female Reproductive Tract  
Marta Rodriguez-Garcia, Fiona D. Barr, John V. Fahey, Charles R. Wira  
Physiology and Neurobiology, Geisel School of Medicine at Dartmouth, Lebanon, NH, United States

**Background:** Successful prevention of sexual transmission of HIV in women requires a substantial increase in our knowledge regarding HIV-target cell availability and regulation in the female reproductive tract (FRT). In this study we analyzed CD4+ T cell phenotype and susceptibility to HIV-infection in three different FRT compartments likely involved in HIV-acquisition: endometrium (EM), endocervix (CX) and ectocervix (ECX).

**Methodology:** Tissues from EM, CX and ECX from pre- and post-menopausal women were enzymatically digested and CD4+ T cells isolated with magnetic beads. CD4+ T cell phenotype was analyzed by flow cytometry and mRNA analysis used to determine transcription factor and cytokine expression. CD4+ T cells were also infected with HIV (BaL) in vitro and p24+ cells analyzed by flow cytometry 6 days after viral challenge.

**Results:** We found that Th17 cells represent a major subset in FRT tissues with differential distribution among sites. In pre-menopausal women, CD4+ T cells in general, and also Th17 cells in particular, were significantly lower in the EM relative to the CX and ECX. Differences in T cell subsets were found between pre- and post-menopausal women in the EM, but not in the CX and ECX. Th17 cells were the main CD4+ T cell population expressing CCR5 and were more susceptible to infection than the other CD4+ T cell subsets. Susceptibility to HIV infection was different between tissues, with CD4+ T cells from the EM being the least susceptible.

**Conclusions:** Unlike the EM, Th17 cells in the CX and ECX are a major population that has increased susceptibility to HIV infection. Differences in Th17 cell distribution may account for differences in HIV-susceptibility between EM, CX and ECX. Our results provide valuable information for designing preventive strategies directed at targeting highly susceptible target cells in the FRT. Supported by NIH contract HHSN27220100001C and NIH grants AI102838 and AI071761 (CRW).

249  Transcriptional Profiling Identifies New Mechanisms of HIV Permissiveness in Primary Th17 Cells  
Aurélie Cleret-Buhot1, 2, Jean-Philippe Goulet3, 4, Patricia Montero1, 2, Annie Bernier1, 2, Annie Gosselin1, 2, Mohammad-Ali Jenabian5, Jean-Pierre Routy6, Elias Haddad6, Rafick Pierre Sekaly7, Cécile Tremblay1, 2, Petronella Ancuta1, 2  
1Microbiology, Infectology and Immunology, Université de Montréal, Montréal, QC, Canada, 2CHUM-Research Centre, Montréal, QC, Canada, 3Ste-Justine Hospital Research Center, Université de Montréal, Montréal, QC, Canada, 4CARTaGENE, Montréal, QC, Canada, 5McGill University Health Centre, Montréal, QC, Canada, 6Vaccine and Gene Therapy Institute, Port St Lucie, FL, United States

**Background:** Th17 cells are major players in mucosal immunity. Th17 cells are highly permissive to HIV infection, while Th1 cells are relatively resistant. As a consequence, Th17 but not Th1 cells are depleted in HIV-infected subjects and their frequency is not restored under antiretroviral therapy. Thus, there is a need for new therapeutic strategies to prevent Th17 cell infection and depletion. We hypothesized that Th17 vs. Th1 cells express a distinctive transcriptional profile compatible with HIV permissiveness.

**Methodology:** Leukapheresis were collected from uninfected subjects (n=10). Th17 (CXCR3-CCR4+CCR6+) and Th1 (CXCR3+CCR4-CCR6-) subsets were sorted by flow cytometry and stimulated via CD3/CD28. Total RNA was extracted (Qiagen). The expression of 47,000 probe-sets was tested using the Illumina technology. Genes were classified by biological function using GO and GSEA. Cytokine production and proliferation was measured by intracellular staining, CFSE dilution assay and flow cytometry. Levels of HIV-p24 and integrated HIV-DNA were measured by ELISA and real-time PCR, respectively. The Am Rev RNA interference technology was used to evaluate the functional role of top-modulated genes.

**Results:** Among 2,533 “present calls”, 1,335 and 1,198 probe-sets were upregulated and downregulated, respectively, in Th17 vs Th1 cells (p-value<0.05; 1.3-fold change cutoff). Genes associated with T-cell differentiation (RORC), TCR signaling (ZAP-70, Lck, MAP3K4), activation/apoptosis (PTPNI3), and HIV replication (PPARG) were upregulated in Th17 cells at a 1.3-fold change cutoff. Genes associated with T-cell differentiation and previously linked to HIV resistance included CCR5 binding chemokines and IFN-induced molecules. By using HIV-FITC-GFP pseudotyped virions, we demonstrate that HIV permissiveness in Th17 vs. Th1 is regulated by both entry and post-entry mechanisms.

**Conclusions:** Our study reveals the transcriptome of HIV permissive Th17 and resistant Th1 cells; identifies RORC, kinases associated with TCR signaling and NF-kB as key regulators of HIV replication in Th17 cells; and demonstrates that HIV permissiveness in Th17 cells is regulated by mechanisms acting at both entry and post-entry levels. Novel therapeutic strategies aimed at interfering with Th17-specific transcripts may limit HIV replication, while preserving the beneficial role of Th17 cells in mucosal immunity.

250  Elevated Soluble CD40 Ligand During HIV Infection Suppresses Dendritic Cell Function  
Meagan O’Brien, Elizabeth Miller, Nina Bhartiwaj  
Mount Sinai School of Medicine, New York, NY, United States

**Background:** Soluble CD40 ligand (sCD40L) levels are increased in various inflammatory states, including human immunodeficiency virus (HIV) infection. sCD40L exists in both monomeric and multimeric forms, however, the majority of circulating sCD40L is monomeric. sCD40L is predominantly released...
by activated platelets, which we have previously shown are increased during antiretroviral-treated HIV disease. In this study we tested the hypothesis that monomeric sCD40L suppresses dendritic cell (DC) function, thus contributing to immune suppression during HIV infection.

**Methodology:** We compared the effects of monomeric versus multimeric sCD40L on monocyte-derived DC maturation after overnight stimulation and cytokine expression following subsequent overnight Toll-like receptor (TLR) stimulation via FACS analysis and cytokine bead arrays. We also evaluated T cell proliferation and Th1-skewing capacity of DCs exposed to monomeric versus multimeric sCD40L following co-culture with carboxyfluorescein succinimidyl ester (CFSE) labeled naïve CD4+ T cells.

**Results:** We found that only sCD40L multimer, but not monomer, matures DCs after overnight incubation, as measured by CD86 surface expression. Furthermore, DCs incubated with sCD40L multimer, but not monomer, enhance T cell proliferation. However, both monomeric and multimeric forms of sCD40L suppress the production of the Th-1 skewing cytokine, IL-12, by DCs in the setting of subsequent TLR stimulation with Poly ICLC (fold change decrease by 3 and 5 respectively). DCs incubated with either sCD40L monomer or multimer suppress Th-1 skewing of naïve CD4+ T cells in the setting of subsequent TLR stimulation with Poly ICLC, as measured by interferon-gamma production.

**Conclusions:** In summary, multimeric sCD40L activates DCs to become potent antigen presenting cells and appropriately downmodulates the ability of DCs to be subsequently stimulated with TLR ligands after initial activation, whereas the predominant monomeric form of sCD40L plays a solely immunosuppressive role on DC function. Thus, elevated levels of monomeric sCD40L during HIV infection may hinder the ability of DCs to stimulate adaptive responses during the course of disease. Future mechanistic studies will define differential signaling pathways induced by monomeric versus multimeric sCD40L in DCs. Future clinical trials will test whether anti-platelet therapy may reduce circulating sCD40L and improve DC function.

**251 Chronic Exposure To Type-I IFN Under Lymphopenic Conditions Alters CD4 T Cell Homeostasis**

Cécile Le Sauvaget1, Rebecca B. Hasley1, Hiromi Imamičhi2, Zhonghui Hu3, Meghan A. Luckey3, Jung-Hyun Park1, Adam Rupert1, Michael Sneller1, H. Clifford Lane1, Marta Catalfamo1

1Laboratory of Immunoregulation, NIAID/NIH, Bethesda, MD, United States, 2Biostatistics Research Branch, NIAID/NIH, Bethesda, MD, United States, 3Experimental Immunology Branch, NCI/NIH, Bethesda, MD, United States

**Background:** HIV infection and the associated chronic immune activation alter T cell homeostasis leading to CD4 T cell depletion and CD8 T cell expansion. During HIV infection the majority of CD8+ T cells are arrested in their differentiation potential at the TM stage and lack effector function. Our analysis of the transcriptional profile of HIV-specific CD8+ T cells from chronic HIV infected patients showed downregulation of the regulator of differentiation, Id2. The steady decline of the CD4 T cell pool during the chronic phase of infection are not totally understood. We hypothesized that the homeostatic response to HIV-induced CD4 T cell depletion occurs in an inflammatory environment rich in Type-I IFNs and driven by HIV replication and that combination of these two distinct forces: lead to a form of immune T cell activation that results in a decline in the CD4 T cell pool and an increase in the CD8 T cells.

**Methodology:** We analyzed the in vitro effects of IL-7 and IFN-α to increase the total expression levels of the Signal Transducer and Activator of Transcription (t-STATs) in CD4 and CD8 T cells from healthy controls (n=12). We also analyzed the relationships between CD4 T cell counts and total levels of STAT-1 (t-STAT-1) in HIV infected patients (n=53). To examine the combine effects of lymphopenia and IFN-α in vivo we developed an animal model in which lymphocytes were adoptively transferred into lymphopenic mice that were receiving chronically administered IFN-α.

**Results:** IL-7 in vitro upregulated the expression levels of t-STAT-1, -2, -3 and enhanced T cell responsiveness to IFN-α as measured by phosphorylation of STAT-1. In patients with HIV infection and suppressed viremia <50 copies/ml, levels t-STAT1 were inversely correlated with the degree of lymphopenia (R=-0.52, p < 0.01 and R=-0.34, p < 0.01) in CD4 and CD8 T cells respectively. In addition, a positive correlation between STAT-1 and IL-7 serum levels was observed in CD4 (R=0.38, p=0.01) but not in CD8 T cells. In a murine model, lymphopenia and chronic treatment with IFN-α led to diminished survival of CD4 T cells and an expansion of CD8 T cells, thus recapitulating the alterations of the homeostasis of these pools observed in patients with HIV infection.

**Conclusions:** IL-7 in vitro and lymphopenia in vivo can modulate T cell responsiveness to Type I IFNs, suggesting a synergistic interaction of these cytokines. Therefore, the persistent stimulation of this pathway in the setting of a lymphopenic host, such as chronic untreated HIV infected patients could be deleterious for CD4 T cell homeostasis and may contribute to the aberrant immune activation and eventual depletion of the CD4 T cells. The analysis of these pathways may contribute to the development of new strategies to reverse the dysregulation of the T cell pools seen in patients with HIV infection.

**252 IL-15 Induces Id2 To Drive Effector Differentiation of CD8 TM and EM Cells While Maintaining CM Pools**

Alessandra Noto1, Francesco A. Procopi1, Julien van Grevenyghede2, Cheryl Cameron1, Courtney Steel1, Amit Sabnis1, Hiroshi Takata1, Franck Dupuy1, Jeff Ahlers1, Rafick-Pierre Sekaly1

1Vaccine and Gene Therapy Institute, PORT SAINT LUCIE, FL, United States, 2Lady Davis Institute, McGill University, Montreal, QC, Canada

**Background:** During HIV infection the majority of CD8+ T cells are arrested in their differentiation potential at the TM stage and lack effector function. Our transcriptional profile of HIV-specific CD8+ T cells from chronic HIV infected patients showed downregulation of the regulator of differentiation, Id2. The common gamma chain cytokines (IL-2, IL-7, IL-15, IL-21) are necessary for the generation and maintenance of virus-specific effector CD8+ T cells. A better understanding of signal transduction pathways involved in the regulation of CD8+ T cells is critical for the development of effective HIV immunotherapies aimed at restoring effector and cytotoxic ability of antigen-specific CD8+ T cells. In this study we have focused on defining the role of IL-15 in promoting CD8+ T cell differentiation and effector function mediated by upregulation of Id2.

**Methodology:** CD8+ T cell subsets were sorted from total PBMCs obtained from healthy volunteers for naïve, CM, TM, EM and EMRA subsets. Gene expression profiles were assessed ex vivo by gene array and after IL-15 or TCR stimulation by multiplex PCR. Shut-down of Id2 was performed by siRNA assay on total memory CD8+ T cells and functional analysis was assessed by flow cytometry. PBMCs from chronic HIV infected patients were stimulated with IL-15 with an optimum HLA class I restricted HIV peptide. At day five we measured activation (Ki67, GrzB) and differentiation of tetramer positive cells
(Id2 levels and CCR7, CD27, CD45RA). Cytolytic activity was measured by a cell-based assay that measures the capacity of HIV-specific CD8+ T cells to kill CD4+ T cells loaded with their cognate peptide.

**Results:** We show that Id2 and its target genes are mostly expressed in human EM and EMRA while being poorly expressed in CM. Silencing of Id2 impacts on T cell survival, proliferation and differentiation. Id2 expression was regulated by TCR but also by IL-15 which was the most effective among common y-chain cytokines in upregulating Id2 expression and inducing proliferation, and survival of CD8+ EM cells. IL-15 induced proliferation of all memory subsets from healthy subjects while inducing differentiation, GzmB production, and cytotoxic effector function of CD8+ TM and EM cells while maintaining CM pool. Stimulation of CD8+ cells from HIV infected subjects with peptide plus IL-15 induced Id2 expression and differentiation of tetramer+ TM cells, and restored their HIV-specific cytotoxic activity.

**Conclusions:** Immunotherapy with agents such as IL-15 treatment that increase Id2 expression levels, in combination with antiretroviral therapy and blocking PD-1 signaling may provide a novel way to restore and enhance the immune response that triggers the functional re-activation of HIV-specific CD8+ T cells and the killing of latent HIV infected CD4+ T cells.

253  **Double Stranded RNA Stimulates IL-1β Secretion in Cervical Epithelial Cells via the Inflammasome**

*Melis N. Anahtar, Maud Deruaz, Andrew M. Tager, Douglas S. Kwon*

Ragon Institute, Massachusetts General Hospital, Cambridge, MA, United States

**Background:** The female genital tract (FGT) is a critical mucosal site for HIV transmission, and inflammation in the FGT prior to HIV exposure is thought to facilitate HIV infection. IL-1β is one of the key pro-inflammatory cytokines associated with HIV acquisition risk in women when detected at high levels in cervicovaginal (CV) lavages. Little is known about the mucosal factors that induce CV IL-1β secretion, but identification of the stimuli and inflammatory pathways could lead to anti-inflammatory interventions that may reduce HIV acquisition risk. We hypothesize that pathogen-associated molecular patterns (PAMPs) lead to activation of the inflammasome in the FGT, resulting in IL-1β secretion.

**Methodology:** To determine whether PAMPs induce inflammasome activation in the female genital tract, primary human immortalized endocervical (End1) and ectocervical (Ect1) epithelial cell lines were treated with TLR 2/6, 3, 4, 7/8, and 9 ligands followed by ATP. Activated caspase-1 was measured with a fluorescent probe and detected by flow cytometry, with exclusion of necrotic cells using propidium iodide. IL-1β and IL-1β secreted from both End1 and Ect1 cells (p<0.01), while other TLR ligands did not. TLR3, RIG-I, and NLRP3 were expressed at baseline in both End1 and Ect1 cells and upregulated by poly(I:C) treatment. In response to poly(I:C) but not LPS and FSL1, End1 and Ect1 cells strongly upregulated expression of human beta defensin 2 and IFN-β. In vivo, repeated intravaginal treatment of poly(I:C) in humanized mice induced secretion of pro-inflammatory cytokines like human IL-1β and IFN-α2, as well as T cell chemoattractants such as RANTES and MIP-1β.

**Results:** The TLR3 and RIG-I agonist poly(I:C) induced a two-fold increase in activated caspase-1 in End1 cells (p<0.05), and ODN2006 induced a three-fold increase in End1 and Ect1 cells (p<0.05) relative to no treatment. Poly(I:C) treatment also caused a significant and dose-dependent increase in IL-1β secretion from both End1 and Ect1 cells (p<0.01), while other TLR ligands did not. TLR3, RIG-I, and NLRP3 were expressed at baseline in both End1 and Ect1 cells and upregulated by poly(I:C) treatment. In response to poly(I:C) but not LPS and FSL1, End1 and Ect1 cells strongly upregulated expression of human beta defensin 2 and IFN-β. In vivo, repeated intravaginal treatment of poly(I:C) in humanized mice induced secretion of pro-inflammatory cytokines like human IL-1β and IFN-α2, as well as T cell chemoattractants such as RANTES and MIP-1β.

**Conclusions:** Poly(I:C) induces IL-1β secretion when applied to human cervical epithelial cells in vitro and humanized mice in vivo. The mechanism of IL-1β secretion appears to be inflammasome mediated, as measured by caspase-1 activation, and NLRP3 and RIG-I are potential triggers. Future work will determine which bacteria and viruses are associated with genital IL-1β secretion and the potential role in mediating risk of HIV acquisition in women.

254  **Alpha-Defensins Modulate HIV Transcytosis: Role of STI-Mediated Enhancement of HIV Transmission**

*Kimyata Valere1, Aprille Rapista2, Alison J. Quayle3, Wuyan Lu4, Eliseo Eugenin1, Theresa Chang1*

1Public Health Research Institute, Department of Microbiology and Molecular Genetics, Rutgers University-New Jersey Medical School, Newark, NJ, United States; 2Public Health Research Institute, Newark, NJ, United States; 3Louisiana State University Health Sciences Center, New Orleans, LA, United States; 4Institute of Human Virology, University of Maryland School of Medicine, Baltimore, MD, United States

**Background:** Sexually transmitted infections (STIs) increase the likelihood of HIV transmission. Defensins are antimicrobial peptides important for innate immunity at the mucosa. Alpha-defensins, including human neutrophil defensins 1-3 (HNPs1-3) and human defensin 5 (HD5), are elevated at the genital mucosa in individuals with STIs, suggesting their role in early events of HIV infection. HD5 and HD6 promote HIV infectivity and contribute to enhanced HIV infection of conditioned media from Neisseria gonorrhoeae-exposed female genital epithelial cells. In contrast to HD5 and HD6, HNPs exhibit anti-HIV activity in vitro; however, increased levels of HNPs have been associated with enhanced HIV acquisition. HIV can cross the mucosal epithelium by transcytosis. In this study, we examined the effect of alpha-defensins on tight junction formation, permeability, and HIV transcytosis in polarized epithelial cells.

**Methodology:** Endocervical (A2EN) or intestinal (Caco) epithelial cells were grown and polarized in 24-well transwell inserts for 7 days. Defensins were added to the apical side of polarized cells and incubated for 24 and 48h. Tight junction was assessed by immunostaining with antibodies against ZO-1 or occludin. Transepithelial resistance was measured by an EVOM voltmeter or by cellZscope to monitor the physical barrier function. HIV transcytosis was determined by addition of HIV-1BAL at the apical side of epithelial cells followed by monitoring HIV at the basolateral side using HIV p24 ELISA.

**Results:** Alpha-defensins caused discontinuation of tight junctions and nuclear localization of occludin in polarized epithelial cells. HNP-1 significantly increased the epithelial permeability. The levels of transcytosed HIV were increased in defensin-treated polarized epithelial cells compared to untreated control.
Conclusions: Our results show that defensins can affect the integrity of the mucosal epithelium, leading to an increase in HIV transcytosis. Our study offers a new role of defensins in enhancement of HIV transmission in the setting of sexually transmitted infections.

255 Exposure To IFNαx Leads To Generation of IL-10-Producing Tr1 Cells
Clara Lehmann1, Kristina Koch1, Nora Koch1, Pia Hartmann1,2, Gerd Fätkenheuer1, Fabio Romerio3
1First Department of Internal Medicine, University of Cologne, Cologne, Germany, 2Institute for Medical Microbiology, Immunology and Hygiene, University of Cologne, Cologne, Germany, 3Institute of Human Virology, University of Maryland School of Medicine, Baltimore, MD, United States

Background: In HIV-1 infection elevated serum levels of interferon alpha (IFNα) and Interleukin-10 (IL-10) are associated with immune hyperactivation and disease progression. Recently, coexpression of CD49b and LAG-3 was shown to identify Type 1 regulatory cells, which secrete large amounts of the immunosuppressive cytokine IL-10. This study aimed at assessing whether IFNα production during HIV infection might directly cause immune activation and increased expression of Tr1 cells.

Methodology: Plasmacytoid dendritic cells (pDC) (BDCA2+CD123+) and Tr1 (CD3+CD4+CD49b+LAG-3+) cells in peripheral blood of seronegative controls (n=10) and HIV-1+ subjects (viremic: n=15; elite controllers n=5) were quantified by flow cytometry. Spontaneous IFNα and IL-10 expression was assessed by cytokine secretion assays. In an in vitro model of primary antigen-driven immune response, CD4+ T cells from uninfected donors were activated and expanded for 7 days with monocyte-derived dendritic cells (MDDC) in the presence (or absence) of 10 ng/ml IFNα supplied every second day. We used cytokine expression to profile CD4+ T cell subsets (IFN-γ and IL-2 for Th1; IL-4 for Th2; IL-10 for Tr1; IL-17 for Th17 generated in the presence or absence of IFNα. Data (expressed as mean and standard error of the mean, SEM) were analyzed using Mann Whitney tests.

Results: We found higher frequency of circulating Tr1 cells in viremic HIV-1+ patients (1.2% ± 0.5) vs. elite controllers (0.5% ± 0.2; p<0.05). In contrast, lower frequency of circulating pDC was observed in viremic (0.2% ± 0.02) vs. elite controllers (0.5% ± 0.07; p=0.01) vs. controls (0.8% ± 0.08; p<0.0001). Elevated IFNα secretion (geometric mean fluorescence intensity, GMFI) was found in viremic patients (12.4 ± 1.28) vs. elite controllers (4.4 ± 1.2; p=0.02) and controls (Mean 8.9 ± 2.9; p=0.012). CD4+ T cells activated and expanded in vitro in the presence of IFNα expressed lower levels of Th1, Th2 and Th17 cytokines, and higher levels of the Tr1 cytokine IL-10.

Conclusions: Our results suggest that over-expression of IFNα during HIV-1 infection drives the generation of Tr1 cells that produce the immunosuppressive cytokine IL-10.

256 TNF Drives Foam Cell Formation by Monocytes From HIV+ Donors in an In Vitro Atherosclerosis Model
Anna Mais1, Candida F. Pereira1,2,3, Thomas A. Angelovich1,4, Jing-Ling Zhu1, William A. Muller1, Anna C. Hearps1,4, Suzanne M. Crowe1,3, Anthony Jaworowski1,3
1Burnet Institute, Melbourne, Australia, 2Centre for Biomedical Research, Burnet Institute, Melbourne, Australia, 3Department of Infectious Diseases, Monash University, Melbourne, Australia, 4School of Applied Sciences, RMIT University, Melbourne, Australia, 5Northwestern University, Chicago, IL, United States, 6Department of Infectious Diseases, Monash University, Melbourne, Australia

Background: HIV+ individuals have an increased risk of cardiovascular disease (CVD) which is independent of traditional risk factors, but the mechanisms driving this are unknown. We have recently shown that monocytes are activated in HIV+ patients despite combination antiretroviral therapy, and that this is associated with chronic inflammation. The migration of monocytes across endothelial blood vessel walls into developing plaques is a critical early event in atherosclerosis. We hypothesize that inflammation increases the proatherogenic properties of monocytes and drives CVD in HIV+ individuals.

Methodology: We have developed an in vitro model of atherosclerotic plaque formation, which enables monocyte transendothelial migration to be studied using purified donor monocytes and primary endothelial cells. We measured the rates of forward and reverse transendothelial migration, and also the propensity of monocytes to ingest lipids and become inflammatory foam cells (associated with plaque progression) using a combination of phase contrast- and fluorescent live cell microscopy and flow cytometry.

Results: Monocytes from HIV+ individuals showed increased foam cell formation and an impaired ability to migrate out of our atherosclerotic plaque model (p<0.05 for all, n=16 HIV+ donors and 7 controls). Serum from virologically suppressed HIV+ individuals contained higher concentrations of TNF (median 5.7 vs 3.5 pg/ml for controls, p=0.016) and increased foam cell formation in autologous HIV+ as well as uninfected control monocytes. As expected, TNF increased monocyte migration but we additionally found that blocking TNF receptor ligation post migration inhibited foam cell formation (38.9% vs 7.5% for controls (5.7 vs 3.5 pg/ml for controls, p=0.016) and 59.1% vs 10.8%, p<0.0001 for HIV+ monocytes). Live cell imaging confirmed monocytes from HIV+ individuals showed reduced post-migration speed, consistent with increased foam cell formation. Flow cytometric analysis of foam cells showed greater intracellular TNF than non-foamy migrated macrophages, revealing their pro-inflammatory nature.

Conclusions: Monocytes in HIV+ individuals are primed for foam cell formation following transendothelial migration. In addition to established effects on endothelial cells to promote leukocyte migration, TNF also increases the propensity for monocytes to develop into inflammatory foam cells and thus become retained in subendothelial plaques. Elevated TNF levels persist in HIV+ individuals despite virological suppression and may contribute to increased risk of atherosclerosis. These data provide a critical mechanistic link between chronic inflammation, monocyte activation and increased CVD risk in HIV+ individuals.

257 HIV-Altered mRNA Expressions of Type 1 IFN Pathway Related To Activation/Exhaustion in CD4+ T Cells
Chi-Lin Lee1, Erik Serrao1,2, Toni Frederick1, Chia-Hao Wang1, Andrea Kovacs1
1Department of Pediatrics, Keck School of Medicine, University of Southern California, Los Angeles, CA, United States, 2Pharmacology and Pharmaceutical Sciences, University of Southern California, Los Angeles, CA, United States

Background: Recently, the LCMV model study suggests a mechanism whereby persistent viruses modulate Type I Interferon (IFN)-signalling during chronic infection leading to hyperactivation and immune exhaustion in mice. HIV+ patients treated with peg-IFN-α had sustained virologic suppression and...
Dysfunctional High Density Lipoprotein Directly Upregulates T Cell Activation in HIV-1 Infection

Theodoros Kelesidis, Judith Currier, Diana Huynh, Sangeun Park, Hwee Ng, Otto O. Yang

Background: The mechanisms that drive immune activation in HIV-1-infection remain unclear. We have recently shown that HIV-1-infected subjects have dysfunctional (oxidized) HDL that is associated with biomarkers of T cell activation. Herein, we investigated whether in vivo modified native dysfunctional HDL from HIV-1 infected subjects (HIV-HDL) and in vitro oxidized HDL (HDLox) directly upregulate T cell proliferation and activation in vitro.

Methodology: HIV-HDL was isolated from HIV-1 infected subjects (n=8) with suppressed viremia (HIV-1 RNA <50 copies/mL) on antiretroviral therapy (ART) known to have dysfunctional HDL based on a validated biochemical assay. Pooled HDL from healthy subjects was oxidized in vitro using an in vivo generated potent lipid oxidant (Drug Metab Lett. 2010; 4:139-48)(HDLox). Peripheral blood mononuclear cells (PBMCs) from HIV-1 infected (n=15) and uninfected subjects, further studies are warranted to evaluate whether modified lipoproteins may contribute to T cell activation in HIV-1 infection despite successful virologic therapy.
Dysfunctional High Density Lipoprotein Directly Reduces HIV-1-Specific Antiviral Responses

Theodoros Kelesidis, Judith Currier, Diana Huynh, Sangeun Park, Hwee Ng, Otto Yang
Medicine, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, United States

Background: Oxidized lipids play key roles in both viral replication and T cell biology and oxidized lipoproteins may directly affect adaptive immunity. High density lipoprotein (HDL) has many functions including the disposal of oxidized lipids. However, in systemic inflammatory states, it can become oxidized (HDLox) and dysfunctional. To examine effects of oxidized HDL that may potentiate HIV-1 replication and further drive immune activation we evaluated the in vitro effects of HDLox on the antiviral activity of HIV-1-specific CD8+ T-cells (CTLs).

Methodology: Pooled HDL from healthy subjects was oxidized in vitro using 13(S)-hydroperoxy-9Z, 11E-octadecadienoic acid (13(S)-HPODE), an in vivo generated potent lipid oxidant that has previously been shown to modify HDL in vivo and make it dysfunctional. T1 cells were infected with HIV-1 NL4-3.1 at low multiplicity and cultured with or without HIV-1 specific CTLs (Figure) in the presence of normal HDL or HDLox (50-100 ug/ml). Viral replication was assessed by p24 ELISA. At six days after infection virus suppression was quantified by using a virus suppression assay and was calculated as:

\[
\text{"Suppression"} = (\log_{10} \text{pg/ml p24 antigen without CTL}) - (\log_{10} \text{pg/ml p24 antigen with CTL}) \text{ and Virus Suppression Efficiency as: "Suppression Efficiency"} = \frac{\text{"Suppression"}}{(\log_{10} \text{pg/ml p24 antigen without CTL})}.
\]

Paired T-test was used for comparison of values between pairs.

Results: A representative experiment from a Gag-specific CTL clone is shown in Figure 1A. HIV-1-specific CTLs reduced Log10 pg/ml p24 antigen and suppressed virus replication but HDLox reduced the suppression efficiency of HIV-1-specific CTLs in a dose-dependent way (Figure).

Conclusions: Dysfunctional (oxidized) HDL but not normal HDL reduced the ability of HIV-1-specific CTLs to suppress viral replication. Thus, oxidized HDL may contribute to viral persistence in vivo through dysfunction of cellular antiviral immunity. Since HIV-1 infected subjects have dysfunctional HDL compared to uninfected subjects, further studies are warranted to evaluate whether modified lipoproteins may contribute to immune activation in HIV-1 infection.

HLA Gene Loci Associated With HIV Load in CSF and Blood Plasma in the CHARTER Cohort

Benjamin B. Gelman1, Sunil K. Ahuja2, Ronald J. Ellis3, Scott Letendre4, Christina M. Marra5, Justin McArthur6, Susan Morgello7, David B. Clifford8, Igor Grant9, Florin Vaida10, The CHARTER Group
1 Pathology, University of Texas Medical Branch, Galveston, TX, United States, 2 Medicine, University of Texas Health Science Center at San Antonio, San Antonio, TX, United States, 3 Neurology, University of California - San Diego, San Diego, CA, United States, 4 Medicine, University of California -San Diego, San Diego, CA, United States, 5 Medicine, University of Washington, Seattle, WA, United States, 6 Neurology, The Johns Hopkins University, Baltimore, MD, United States, 7 Neurology, Icahn School of Medicine at Mount Sinai, New York, NY, United States, 8 Neurology, Washington University, Saint Louis, MO, United States, 9 Psychiatry, University of California - San Diego, La Jolla, CA, United States, 10 Family and Preventive Medicine, University of California -San Diego, San Diego, CA, United States

Background: Polymorphic gene loci in the major histocompatibility complex (HLA) are associated with better control of HIV in plasma of patients with European but not African ancestries. To determine whether HLA alleles influence HIV replication in the CNS, we compared cerebrospinal fluid (CSF) HIV with HLA genotypes.
Methodology: HLA-C*-35 (rs9264942) and HLA-B*5701 (rs2395029) were identified using PCR in 564 blood DNA isolates from HIV-infected patients in the CHARTER cohort. HIV RNA log10 copy per ml was determined in plasma and CSF and differences in patients with versus without the two HLA polymorphisms were assessed using Fisher's exact test, T test, or Wilcoxon rank sum test.

Results: In 48 treatment naïve European subjects the C allele of HLA-C*-35 was associated with lower HIV concentration in plasma (TT = 4.45 log c/ml, CT = 4.30 log c/ml, CC = 3.60 log c/ml, p = 0.034) but not in CSF (p = 0.61). In 205 Europeans on combination antiretroviral therapy (cART), HLA-C*-35 was not associated significantly with plasma or CSF HIV RNA concentration. In treatment naïve Europeans the HLA-B*5701 analysis resembled the HLA-C*-35 results for plasma (+ = 4.49 log c/ml, - = 3.19 log c/ml, p = 0.032) and CSF HIV (p = 0.20). Unexpectedly, in the 164 treated patients of African descent, those with the C allele of HLA-C*-35 had greater detection of HIV (worse HIV control) (plasma, 73% versus 38%, p = 0.012; CSF, 45% versus 19%, p = 0.017). The number of treated Africans that possessed an HLA-B*5701 allele was too small to yield a meaningful result. No association between HLA-C*-35 or HLA-B*5701 type and HIV RNA concentration in plasma or CSF was observed in 33 treatment naïve patients of African ancestry.

Conclusions: Plasma but not CSF HIV RNA concentration was lower in HLA-C*-35/C and HLA-B*5701/+ treatment naïve patients of European descent. This effect was not seen in treated individuals, likely because the treatment effect overshadows the genetic effect. In contrast, treated patients of African descent with HLA-C*-35 C alleles had higher plasma and CSF HIV RNA concentrations. This association was not seen in the patients not on cART and suggests that those subjects are less likely to attain virologic suppression in plasma or CSF.

261 GUAVAh: A Compendium of Host Genetic Data in HIV Biology and Disease
Istvan Bartha1,2, Paul J. McLaren1, Angela Ciuffi2, Jacques Fellay1,2, Amalio Telenti2
1Ecole Polytechnique Federale De Lausanne, Lausanne, Switzerland, 2Institute of Microbiology, University Hospital Lausanne, Lausanne, Switzerland

Background: There are increasing amounts of data on host genes that are modulated during HIV infection, influence disease susceptibility and that carry genetic variants that impact HIV infection. We created GUAVAh (Genome Updates of Associations and Viral Analyses in HIV) a public resource that supports multipurpose analysis of genome-wide genetic variation and transcriptome profile across multiple data sets and phenotypes in HIV biology.

Methodology: We included original data from 11 genome and transcriptome studies addressing viral and host responses in vivo, ex vivo and in vitro and transcriptome data including diverse phenotypes such as HIV acquisition, viral load, disease progression, viral life cycle, latency and viral host genome interaction. This represents genome-wide association data from more than 14,000 individuals, exome sequencing data from 400 individuals, the publicly available GUAVAh framework supports queries on (i) unique single nucleotide polymorphism across different study phenotypes, including viral escape sites, (ii) gene structure and variation with possible relevance to HIV biology, (iii) gene expression in the setting of human infection (CD4 and CD8 T cells), and (iv) RNA-seq data in the setting of in vitro models of permissive infection and in primary cell latency and reactivation.

Conclusions: The complexity of the analysis of host gene influences on HIV biology and pathogenesis calls for comprehensive motors of research on curated data. The tool developed here allows queries and supports validation of the rapidly growing body of host genetic information pertinent to HIV research.

262 HIV-1 Infection Leads To Increased Expression of HML-2 Proviruses In Vivo But Not Virion Production
Neeru Bhardwaj1, Frank Maldarelli3, John Mellors3, John M. Coffin1
1Tufts University, Boston, MA, United States, 2National Cancer Institute, Frederick, MD, United States, 3University of Pittsburgh, Pittsburgh, PA, United States

Background: Human endogenous retrovirus (HERV) sequences make up ~8% of our genome. One group of HERVs, HERV-K (HML-2), includes the most recently integrated proviruses, present as both fixed and polymorphic loci in the population. Some HML-2 proviruses have retained ORFs for the retroviral genes gag, pro, pol and env. Interestingly, increased HML-2 expression is found in a variety of human disease states, particularly cancers. In particular, HML-2 viral particles have been detected in the plasma of HIV-1 infected individuals. It is unknown how expression is activated or whether it affects HIV-1 pathogenesis.

Methodology: To further investigate HML-2 expression, a specific quantitative PCR was designed based on a comprehensive alignment of all known HML-2 proviruses. This assay is capable of detecting 51 out of the 91 known HML-2 proviruses in the human genome, is highly reproducible and provides a solid basis for expression analysis in HIV-1 infected individuals.

Results: HML-2 RNA expression was assessed in plasma previously collected from HIV-infected individuals (n=9) and from subjects recruited in an ongoing clinical study (n=6). Contrary to previous studies, HML-2 RNA was not detected in the plasma of infected individuals. A robust signal for HML-2 was detected only when the extracted nucleic acid was not DNase-treated prior to reverse transcription. While this condition led to high levels of signal as seen in published reports, such signal could be attributed entirely to the presence of cellular DNA. HML-2 RNA expression was increased in PBMCs from HIV-1 infected individuals (n=19) as compared to uninfected controls (n=13; 2.1 fold increase, p < 0.0001). The level of HML-2 expression in PBMCs was not related to patient use of antiretrovirals or HIV-1 plasma RNA, cellular RNA or cellular DNA levels. In order to investigate the source of HML-2 RNA expression, HIV-1 infected and uninfected patient PBMCs were sorted into CD3+ CD4+, CD3+CD8+, CD3-CD14+ and CD3-CD20+ cell subsets and then analyzed for HML-2 RNA levels. No single cell subset was enriched for HML-2 RNA expression in HIV-1 patients, but there appears to be substantial variability in the level of HML-2 expression dependent on the cell type.
Conclusions: Our study shows that expression of HML-2 as virus in HIV-1 infected individuals is not universal in that HML-2 virions may not be produced; however, HML-2 viral RNA appears to be upregulated in PBMCs from HIV-infected individuals. Cell sorting and expression analysis did not identify a specific cellular source of HML-2 RNA in HIV-1 infected patients. In fact, HML-2 RNA expression was detected in all cell subsets. This study reveals the complexity of HML-2 RNA expression during HIV-1 infection and the need for additional studies to clarify its effects on HIV-1 pathogenesis.

263 Exome Sequencing To Evaluate the Impact of Rare Coding Variation On HIV-1 Control
Paul J. McLaren1, Patrick R. Shea2, David B. Goldstein3, Jacques Fellay4
1Life Sciences, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, 2Center for Human Genome Variation, Duke University School of Medicine, Durham, NC, United States

Background: Common variants (>5% frequency) in the MHC and CCR5 regions are known to influence set point HIV-1 viral load (spVL) yet explain only a portion of the total trait variance. The impact of rare coding variation on HIV-1 disease progression has not been as thoroughly investigated. Here we utilize exome sequencing in 392 HIV-1 infected individuals with stable spVL to look for rare and functional variants that mediate control of HIV-1 infection.

Methodology: Set point HIV-1 viral load was calculated as the average of at least 3 measurements obtained during the chronic phase of infection. We captured and sequenced all coding exons in 392 HIV-1 infected individuals of the Swiss HIV Cohort Study using the Illumina Truseq 65Mb enrichment kit and the Illumina HiSeq2000. Quality control and variant calling were performed using the GATK and variant functional annotation was performed using snpEff version 3.3. Individual variants were tested for association using linear regression. Testing of the combined effects of multiple low frequency variants across each of > 18,000 genes was performed using SCORE-Seq and SKAT.

Results: Consistent with previous results, single marker variant tests showed a strong signal of association in the MHC. The top association was observed between spVL and rs11314446 (p=2.3x10-11) in exon 3 of HLA-B. Conditioning on this SNP, residual association was observed at rs2308622 (conditional p=2.2x10-6) in HLA-C. Accounting for these two SNPs, no other variants showed evidence for association. Analyses aimed at detecting the combined effect of multiple low frequency variants within a gene showed no significant associations. Restricting this analysis to only those variants that result in a change in protein sequence did not reveal further signals.

Conclusions: Outside of the MHC, no significant impact of rare variation on spVL was detected by exome sequencing in 392 individuals. Larger samples are likely required to fully explore the role of rare coding variation on this phenotype. Additional classes of variation not detected by GWAS or current sequencing technologies may also contribute to host HIV-1 control.

310 Increased Immune Activation After Gut Permeabilization in SIV-Infected African Green Monkeys
Jan Kristoff1, Thaidra Gauthier2, Rajeev Gautam3, Dongzhu Ma3, Jacob Estes4, Russell Tracy5, Cristian Apetrei3, Steve Nelson6, Gregory Bagby6, Ivona Pandrea1
1Center for Vaccine Research, University of Pittsburgh, Pittsburgh, PA, United States, 2UCLA, Los Angeles, CA, United States, 3Center for Vaccine Research, NIAID/NIH, Bethesda, MD, United States, 4NCI/NIH, Frederick, MD, United States, 5University of Vermont, Colchester, VT, United States, 6Louisiana State University, New Orleans, LA, United States

Background: Microbial translocation (MT) has been proposed as a major cause of increased immune activation in HIV/SIV infection and subsequent cardiovascular comorbidities, including hypercoagulability. Our hypothesis was that alcohol administration to African green monkeys, that maintain a healthy intestinal barrier despite high levels of viral replication during chronic SIV infection, will result in increased gut permeability and consequent levels of immune activation and hypercoagulability.

Methodology: Six AGMs were administered ethanol by indwelling gastric catheters for 3 months, and then intravenously infected with SIVsab92018. Alcohol administration continued for up to 6 months postinfection. We compared levels of viral replication, T cell changes, immune activation (HLA-DR, CD38, and Ki-67), MT (LPS, sCD14), coagulation (D-Dimer) and plasma cytokines in alcohol-treated infected AGMs and infected AGM controls. Microbial products and fibrosis were assessed in the liver by immunohistochemistry.

Results: Alcohol administration to AGMs altered the mucosal barrier and resulted in increased MT, as illustrated by the significantly higher levels of LPS and sCD14 in alcohol receiving AGMs, and increased levels of microbial products in the liver. In addition, alcohol administration induced increased levels of T cell activation and proliferation and higher levels of proinflammatory cytokines (IL-1b, IL-6, IL-17) in the treated animals compared to controls. Furthermore, alcohol administration resulted in a slight increase of plasma viral loads in acutely SIVagm-infected AGMs and a delayed CD4+ T cell restoration in the gut and periphery. Numerous inflammatory infiltrates and increased fibrosis were observed in the liver in the alcohol treated AGMs. Finally, induction of MT in alcohol-treated AGMs infected with SIVagm resulted in significantly higher levels of the coagulation biomarker D-dimer.

Conclusions: Our study confirmed that alcohol plays a role in permeabilizing the gut and is increasing MT in African green monkeys, a nonhuman primate model that maintains gut integrity during SIV infection despite high viral replication. Alcohol treatment of SIVagm-infected AGMs resulted in increased systemic immune activation and inflammation, delayed immune restoration, and activation of coagulation. Our results bring direct proof that MT is one of the important mechanisms of excessive immune activation/inflammation and a major cause of cardiovascular comorbidities in HIV infected patients.
311 Breaches in Colonic Claudin-4 Expression Correlate With T-Cell Activation in HIV-1 Infection

Louise Greathed1, Anna Mroz1, Hiromi Kudo1, Brian Gazzard2, Mark Nelson2, Robert D. Goldin1, Alan Steel1, Peter Kelleher1

1Imperial College, London, United Kingdom, 2Chelsea and Westminster Hospital NHS Trust, London, United Kingdom

Background: Disruption of the mucosal barrier leading to microbial translocation has been suggested as a cause of systemic immune activation in HIV-1 infection. Dysregulation of the tight junction protein network, which contribute to maintaining barrier function, has previously been described in HIV-1 infected patients. We sought to determine if HIV-1 infection is associated with changes in the immunohistochemical staining pattern of the tight junction proteins claudin-4, previously not investigated in HIV infection, and claudin-1. We also measured T cell activation and levels of bacterial 16s ribosomal DNA in the blood of HIV-1 infected patients to determine if tight junction abnormalities correlate with levels of microbial translocation and systemic immune activation.

Methodology: Paired blood and colonic samples were collected from 19 healthy controls and 35 HIV-1 infected patients (25 on suppressive ART and 10 untreated). Claudin-1 and 4 staining was performed on tissue sections by indirect immunohistochemistry. Quantitative image analysis was performed using high-resolution scans of whole tissue sections. Microbial translocation was assessed using quantitative real time PCR and HLA DR and CD38 was measured on memory T cells by flow cytometry to assess immune activation. Differences between groups were identified using Kruskal-Wallis test with Dunn’s Multiple Correction and correlations were performed using Spearman’s Rho. Median values are reported in the results.

Results: HIV-1 infection was associated with disruption of claudin-1 and claudin-4 staining at the apical surface of colonic epithelial cells (breach/intact ratios: claudin-1: control=0.23, viraemic=7.32, aviraeamic=1.15; claudin-4: control=0.60, viraemic=4.22, aviraemic=1.96, all p<0.001). The magnitude of claudin-4 disruption was positively correlated with levels of 16s ribosomal DNA in plasma (p=0.005, rs=0.505) and CD4 and CD8 T cell activation (p=0.030, rs=0.367 and p=0.002, rs=0.499 respectively) in the grouped HIV cohort. Levels of viraemia in untreated infection were also positively correlated to claudin-4 disruption (p=0.026, rs=0.750).

Conclusions: Alterations in the distribution of expression of the epithelial gap junction proteins may contribute to the pathogenesis of HIV-1 infection. The magnitude of claudin-4 disruption is directly correlated to the level of HIV viremia, which supports in vitro studies showing HIV viral components may directly impair the integrity of the mucosal barrier. The significant association of 16s rDNA and systemic T cell activation with claudin-4 breaches supports the hypothesis that disruption to the mucosal barrier leads to increased microbial translocation and systemic T cell activation.

312 Rapid Gut-Homing of Plasmacytoid Dendritic Cells During Acute SIV Infection

Haiying Li, Jacqueline Gillis, R. Keith Reeves

NEPRC, Harvard Medical School, Southborough, MA, United States

Background: Lentivirus infections are characterized by a rapid loss of mucosal CD4+ T cells and breakdown of the gut mucosa. In addition, multiple studies have shown that IFN-α-producing plasmacytoid dendritic cells (pDC) are activated early after lentivirus infection, but despite the importance of the gut mucosa in HIV/SIV pathogenesis, little is known about pDCs in these tissues during acute infection.

Methodology: This planned sacrifice study included a total of 21 rhesus macaques - six naïve and six infected with SIVmac239 sacrificed at 14 days post-infection, and nine infected with SIVmac239 sacrificed in chronic stage disease. Animals had colorectal and lymph node biopsies prior to infection, were followed longitudinally by blood collection and full tissue collections were performed at necropsy. Phenotypic and functional analyses were performed using polychromatic flow cytometry.

Results: During acute SIV infection the frequency of pDCs in blood declined rapidly, as early as day 3 post-infection, with an ~5-fold loss by day 14, inversely correlating with viral load (R = -0.55, p < 0.001). Furthermore, when compared to naïve controls, pDC frequencies in animals sacrificed at day 14 post-infection were reduced 5- to 10-fold in lymphoid organs including liver and spleen, but were generally unchanged in lymph nodes. This overall loss in blood and vascular organs coincided with 2- to 8-fold increases in pDCs in colon and jejunum. Of note, when comparing individual animals pDC frequencies in colorectal tissue at day 14 sacrifice were between 6- and 10-fold greater than pre-infection colorectal biopsies. Also, as early as day 6 the gut-homing receptor, α4β7, increased significantly over baseline on circulating pDCs, peaking at ~day 10 post-infection and suggesting a likely mechanism for increased gut-homing. Interestingly, in all chronically infected animals, pDC numbers remained significantly elevated in the mucosa, regardless of viral load. Clinically, re-distribution of pDCs was significantly associated with markers of activation and correlated with loss of CD4+ T cells in the gastrointestinal tract (R = -0.603, p < 0.001), indicating a potential mechanism of pDC-induced depletion.

Conclusions: Herein we demonstrate evidence for acute and permanent accumulation of pDCs in the gastrointestinal tract during SIV infection. While pDC accumulation in the mucosa could aid in virus control, over-production of IFN-α derived from these cells could also contribute to increase the immune activation, inflammation, and CD4+ T cell death in the gut mucosa commonly associated with progressive lentivirus infections.

313 CCR6+ and CD161+ CD4 T Cell Loss Contributes To The Pathogenesis of SIV Infection in Rhesus Macaques

Colleen S. McGary1, Luca Micci1, Emily S. Ryan1, Maria J. Buzov1, Amy Shaw1, Mathias Lichterfeld2, Guido Silvestri1, Aftab A. Ansari1, Mirko Paiardini1, 3

1Department of Microbiology and Immunology, Emory University, Atlanta, GA, United States, 2Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States, 3Department of Pathology and Laboratory Medicine, Emory University, Atlanta, GA, United States

Background: Determining which subsets of CD4+ T cells are lost during HIV and SIV infections in humans and rhesus macaques (RMs) is a critical component to understanding the pathogenesis of infection. Recent studies have shown that CD4+ T cells expressing CCR6, a chemokine receptor that distinguishes Th17 lineage polarization, and those expressing CD161, found on human Th17 precursors, are depleted from blood during chronic HIV
infection. However, little is known about the kinetics of the depletion of these CD4+ T cell subsets, their levels in lymphoid tissues, and the mechanism behind their loss from peripheral blood during HIV/SIV infection.

**Methodology:** To answer these questions, we used multicolor flow cytometry to compare the levels of CCR6+ and CD161+ CD4+ T cells in the blood of 46 SIV-uninfected and 20 SIV-infected RMs, as well as in 27 SIV-uninfected and 35 SIV-infected sooty mangabeys (SMs), a natural host for SIV in which infection is nonpathogenic. Furthermore, the blood and tissue levels of these CD4+ T cell subsets were longitudinally analyzed in six RMs experimentally infected in vivo with SIVmac239 (i.v.). Memory CD4+ T cells expressing either CCR6 or CD161 (or neither) were then sorted from the blood and LN and the level of SIV gag RNA quantified in each cell subset by digital droplet PCR.

**Results:** CCR6+ (p<0.0001), CD161+ (p<0.0001) and CCR6+CD161+ (p<0.0005) CD4+ T cells were all significantly depleted from the blood of SIV-infected RMs compared to uninfected animals. Differently from RMs, these CD4+ T cell subsets were maintained at healthy levels in SIV-infected SMs. Surprisingly, only CD4+CD161+, and not CD4+CCR6+ T cells, coexpressed the HIV/SIV coreceptor CCR5. Longitudinal data in SIV-infected RMs showed that the loss of CD4+CD161+ T cells is progressive and occurs across all compartments sampled, including blood, LN and rectal mucosa. However, CD4+CCR6+ T cells were lost rapidly from the blood and LN but accumulated in the rectal mucosa. Consistent with the hypothesis of redistribution, we found a negative association between the frequencies of CD4+CCR6+ T cells in blood and those at mucosal sites (p=0.0147). While neither CD4+CCR6+ nor CD4+CD161+ T cells were preferentially infected by SIV in the blood compared to CCR6-CD161- T cells (DN), CD4+CD161+ T cells harbored significantly higher levels of SIV gag RNA compared to DN cells in the LN (p=0.0055).

**Conclusions:** This study provides evidence that a profound depletion of CD161+ and CCR6+ CD4+ T cells contributes to the pathogenesis of SIV infection in RMs. Furthermore, our results suggest a heightened susceptibility of CD4+CD161+ T cells to SIV infection and a redistribution of CD4+CCR6+ T cells to mucosal sites as central mechanisms for the dysregulation of these critical CD4+ T cell subsets during HIV infection.

**314 SIV Vaccine Controllers Prevent Aberrant Accumulation of Follicular CD4 T Cells in Rectal Mucosa**

Geetha H. Mylvaganam1,2, Vijayakumar Velu1,2, Jung-Joo Hong1,2, Shannugalakshmi Sadagopal1,2, Suven Kwa1,2, Rahul Basu1,2, Benton Lawson1, Francois Villinger2,3, Rama R. Amara1,2

1Microbiology and Immunology, Emory University School of Medicine, Atlanta, GA, United States, 2Emory Vaccine Center, Yerkes National Primate Center, Atlanta, GA, United States

**Background:** Chronic SIV/HIV infection promotes an accumulation of virus-infected T follicular helper cells (T-FH cells, PD-1hi, CXCR5+, Bcl6+) in the lymph nodes, an important site of viral replication. However, the fate of these cells and their contribution to viral persistence in the rectal mucosa (rectum), another preferential site of virus replication, is not known. Here we studied the fate of PD-1hi CD4 T cells in the rectum following intrarectal SIV251 infection in a cohort of unvaccinated and DNA/MVA vaccinated rhesus macaques (RM).

**Methodology:** Lymphocytes isolated from the rectum of SIV naïve and SIV infected rhesus macaques (RM) were separated and characterized by multi-color flow cytometry. Sorted cells were used for measuring cell associated viral RNA by qRT-PCR. Cellular localization was determined by immunofluorescence staining.

**Results:** In the SIV-naïve RM, a small fraction of CD4 T cells in the rectum expressed high levels of PD-1 (PD-1hi cells), the majority co-expressed CXCR5 and Bcl-6 (T-FH), and localized to germinal centers (GC) of lymphoid follicles. Following a pathogenic SIV infection, despite a global depletion of CD4 T cells, T-FH cells increased dramatically in animals that failed to control SIV infection below 104 viral RNA copies/ml of plasma at set-point. Similar to uninfected animals, the PD-1hi cells in the non-controller RM expressed CXCR5 and Bcl-6 (T-FH), did not express CCR5, and localized to GC of B cell follicles. Moreover, these PD-1hi CD4 T cells were enriched in viral RNA, indicating that these cells exist as an active site of viral production. In contrast, in vaccine-controllers that maintained viral loads below 104 viral RNA copies/ml of plasma at set-point, the frequency of T-FH cells did not increase, and lower frequencies of CXCR5+ PD-1hi CD4 T cells and higher frequencies of CCR5+ CD4 T cells were observed. This CXCR5lo CCR5+ phenotype suggests a possible altered distribution of these cells away from the GC region of B cell zones towards the T cell zone where anti-viral CD8 T cells predominantly reside. Interestingly, higher frequencies of functional SIV specific CD8 T cells (Granzyme B+ CXCR5+ Gag CM9+ CD8 T cells) were observed in the LN follicles of vaccine-controllers compared to non-controllers.

**Conclusions:** These data demonstrate that SIV-infected T-FH cells accumulate in B cell follicles of the rectum during uncontrolled chronic SIV infection and thus may evade killing by anti-viral CD8 T cells. They also demonstrate that vaccine-mediated SIV control is associated with lack of T-FH cell accumulation. These data warrant the exploration of therapeutic interventions that limit aberrant T-FH accumulation as a means to enhance control of chronic SIV/HIV replication.

**315 Decreased Diversity of Gut Microbiota Is Associated With Immune Status During HIV-1 Infection**

Piotr Nowak1, Babilonia Barqasho2, Ekatarina Avershina1, Kajsa Noyan1, Jan Vesterbacka1, Marius Trossed1, Knut Rud1, Anders Sönnerborg1

1Department of Infectious Diseases, Karolinska Institute, Huddinge, Sweden, 2Department of Laboratory Medicine, Karolinska Institute, Huddinge, Sweden

**Background:** Progressive HIV-1 infection is characterized by dysregulation of the intestinal barrier and chronic systemic inflammation. Translocation of immunostimulatory microbial products is proposed as key mechanism behind this inflammation associated with clinical complications during chronic HIV-1 infection. In this study, we wanted to explore the alterations of the gut microflora in HIV-1 infected patients and if gut microbiota is influenced by antiretroviral treatment (ART).
Methodology: In total, 32 patients and 9 controls were included (median CD4 T cell count: 355 cells/ul (120-1040). Faeces and plasma samples were collected at baseline and for 19 patients at follow up (median 7 months [5-15]) after ART introduction. The samples from three elite controllers (EC) were included at baseline. The patients who were prescribed antibiotics or probiotics for the preceding 2 months, or had infectious diarrhea were excluded. The microbiota composition was evaluated by deep sequencing of 16S rRNA gene with 150 bp Illumina chemistry. Additionally, “classical” markers of microbial translocation (MT) were analysed (LPS and sCD14).

Results: The number of observed bacterial species (richness) was lower in HIV-1 infected patients as compared to controls. The alpha diversity (Simpson index) of bacterial species was decreased at baseline and did not change significantly during ART. At baseline, alpha diversity significantly correlated with CD4 T cell % (r=0.42, p=0.01) and CD8 T cell % (r=-0.37, p=0.03) but not with soluble markers of MT. Moreover, the bacterial composition varied in HIV-1 infected patients with significant decrease of bacteria within the Prevotella and Cyanobacteria group. Gut flora after ART introduction contained more Pseudomonas as compared to baseline and healthy controls samples. Notably, EC had high alpha diversity and microbiota composition that resembled status of uninfected controls.

Conclusions: Collectively, the data show that gut microbiota is altered during HIV-1 infection and correlates with immune status. ART influences its composition. The higher similarity of gut microbiota between EC and healthy controls implicate that a healthy state of gut microbiota may be associated with delayed disease progression.

316 Dysbiotic Bacteria Translocate in Progressive SIV Infection

Zachary Klase1, Elias Schwartzman1, Alexandra Ortiz1, Lauren Canary1, Mariam Quinones2, Jason Brenchley1
1Laboratory of Molecular Microbiology, NIAID/NIH, Bethesda, MD, United States, 2NIAID/NIH, Bethesda, MD, United States

Background: Chronic gastrointestinal (GI) inflammation, a hallmark of progressive HIV/SIV infection is associated with disruption of the gastrointestinal epithelial barrier leading to microbial translocation and contributing to localized and systemic immune activation/inflammation, which drives AIDS disease progression. While most of our knowledge regarding regulation of inflammation has come from protein regulators such as proinflammatory cytokines, transcription factors, etc. recent evidence also suggests critical roles for non-coding RNA molecules called microRNAs (miRNAs) in controlling and managing certain aspects of the inflammatory process.

Methodology: Using TLDA arrays, qRT-PCR, luciferase assays and ISH/Immuno fluorescence methods we profiled changes in miRNA expression and characterized specific differentially expressed miRNAs in colon samples from 10 chronically SIV-infected and 4 control macaques.

Results: After applying multiple comparisons correction 10 miRNAs showed differential expression (3-up and 7-down). Among the 3 upregulated miRNAs was miR-34a, previously linked to inflammation, cell cycle arrest, apoptosis and cellular senescence. Further, miR-34a showed statistical significant upregulation in both epithelial and lamina propria leukocyte (LPL) compartments. Interestingly, the intensity of the DNA damage response marker γH2AX was markedly elevated in colonic epithelium and LPL of chronically SIV-infected macaques and confirmed the reported role of oxidative stress in driving miR-34a upregulation. Luciferase reporter assays validated rhesus macaque SIRT1 (histone deacetylase) and Notch2 (epithelial proliferation and differentiation) genes as direct miR-34a targets.

In contrast to miR-34a, expression of SIRT1 and Notch2 mRNA significantly decreased in both colonic epithelium and LPL. Reduced SIRT1 expression resulted in constitutively enhanced protein expression of the transcriptionally active form of the p65 (acetylated on lysine 310) subunit of NFκB exclusively in the LPL. The intensity and number of acetylated p65 positive cells was markedly elevated in the LPL of chronically SIV-infected macaques compared to uninfected controls and localized to increased numbers of IgA and IgG secreting plasma cells.

Conclusions: These findings provide new insights into the potential role of miR-34a in causing hyperactivation of mucosal plasma cells resulting in their dysfunction and possibly, hypergammaglobulinemia. Our results point to a mechanism where the normal function of SIRT1 as an inhibitor of inflammation and immune activation in the colon is suppressed by elevated miR-34a expression resulting in constitutive expression of the proinflammatory acetylated p65 (lysine 310) subunit of NFκB.
**Results:** Analysis of bacterial DNA found in the tissues of infected animals revealed a preference for members of the phylum Proteobacteria. No bacterial dysbiosis was observed in the colon itself during infection, suggesting that the increased prevalence of Proteobacteria in the tissues was due to preferential translocation of these particular bacterial species. Indeed, 454 analysis revealed a further preference for specific members of this phylum (with motile species frequently observed). Analysis of stool during infection and treatment of animals revealed changes in the metabolic activity of bacteria within the GI tract. The biggest change being observed after the administration of anti-retroviral medication with increased metabolic activity of Proteobacteria. Probiotic treatment seemed to decrease the metabolic activity of these proteobacteria.

**Conclusions:** Proteobacteria preferentially translocate from the GI tract during SIV infection of Asian macaques. Translocating species involved motile flagellated species, some of which can cause disease. suggesting these potentially pathogenic species cause systemic immune activation. Interestingly, metabolic activity of proteobacteria is highest during acute infection (when translocation begins) and increases drastically during HAART treatment. Probiotic administration may potentially counteract this and ameliorate systemic immune activation which could improve the prognosis of ARV-treated, HIV-infected individuals.

**318LB Viral Suppression Was Induced by Anti-PD-L1 Following ARV-Interruption in SIV-Infected Monkeys**

Stephen W. Mason, Srirowmya Sanisetty, Christa Osuna-Gutierrez, So-Yon Lim, Susan Chanelewski, Shalyn Campbell, Daniel Tenney, Scott Balistreri, James B. Whitney

1Discovery Virology, Bristol-Myers Squibb, Wallingford, CT, United States, 2Center for Virology and Vaccine Research, Bristol-Myers Squibb, Boston, MA, United States, 3Center for Virology and Vaccine Research, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, United States

**Background:** BMS-936559, a fully human antibody against huPD-L1, was tested in antiretroviral-suppressed SIVmac251-infected rhesus macaques. The primary endpoints for this study were to assess safety during repeated i.v. administration of BMS-936559, to determine any improvement in the function of SIV-specific T cells and to monitor for effects on viral recrudescence after cessation of ARV therapy.

**Methodology:** 13 MHC-defined rhesus macaques were confirmed to be SIVmac251 positive and ARV treatment was initiated, using a 3-4 drug ARV regimen, for an average of 6 months prior to the administration of BMS-936559. Animals received either BMS-936559 (N=8) or iso-type control antibody (N=5). Multiple immunologic and virologic analyses were used to evaluate ARV regimen efficacy, safety and occupancy of PD-L1 by BMS-936559.

**Results:** Durable virologic suppression of SIVmac251 at ≤50 RNA copies/ml was achieved in all animals with the administration of a well-tolerated ARV treatment regimen. Significant reductions in inflammatory markers were observed during ARV treatment. Repeat dosing of BMS-936559 was well tolerated in all animals with no noted untoward effects based on physical examination and laboratory assessments. Occupancy of PD-L1 by BMS-936559 was observed throughout the dosing period and pharmacokinetic analyses verified exposure of antibody. Perturbations in SIV viral RNA levels were observed after ARV treatment interruption, such that 4 of 8 animals in the BMS-936559 treatment group had a delay in viral load rebound and a significantly lower viral load set point, with 2 animal having undetectable VL for 3-4 weeks after an initial rebound. Changes in proviral DNA levels and T cell functional assays have been assessed.

**Conclusions:** These data provide proof of concept for the safety of repeated high-level dosing of BMS-936559 in vivo. The effects on viral suppression observed in this study may reflect a restoration of immune function by anti-PD-L1 in SIV-infected rhesus monkeys.

**319 A Novel HIV-1mt Encoding CCR5-Tropic Env Established Persistent Infection in Cynomolgus Macaques**

Akatsuki Saito, Kazuhiro Matsuoka, Hirotsuka Ode, Hiyori Otsuki, Takeshi Yoshida, Yasumasa Iwata, Wataru Sugura, Tetsuro Matano, Tomoyuki Miura, Hirofumi Arai

1Center for Human Evolution Modeling Research, Primate Research Institute, Kyoto University, Inuyama, Japan, 2Japan Foundation for AIDS Prevention, Chiyoda-ku, Japan, 3Discovery Virology, Bristol-Myers Squibb, Wallingford, CT, United States, 2Center for Virology and Vaccine Research, Bristol-Myers Squibb, Boston, MA, United States, 3Clinical Research Center, National Nagoya Medical Center, Nagoya, Japan, 4Laboratory of Primate Model, Institute for Virus Research, Kyoto University, Kyoto, Japan, 5AIDS Research Center, National Institute of Infectious Diseases, Shinjuku-ku, Japan

**Background:** With the aim of developing a monkey model of HIV-1 infection, we have been utilizing a combination of macaque-tropic HIV-1 (HIV-1mt) and cynomolgus macaques (CM). While we previously reported that CXCR4-tropic HIV-1mt (X4 virus) replicated efficiently in CM homozygous for TRIM5αp, none of infected animals had persistent viremia. Since most HIV-1 in human population use CCR5 as a co-receptor (R5 virus) during transmission, the co-receptor usage may be important for establishment of persistent infection in monkeys. Based on this hypothesis, we here constructed an R5-tropic HIV-1mt and analyzed viral replication in monkeys.

**Methodology:** The 5’ region (from 5’ LTR to vpu) and 3’ region (from env to 3’ LTR) of viral genome were PCR amplified from X4-tropic HIV-1mt plasmid with high fidelity DNA polymerase. By overlapping with these fragments, a fragment covering env gene was PCR amplified from R5-SHIV MK38 strain that shows pathogenicity in infected rhesus macaques. These amplified fragments were subjected to co-transfection of stably CCR5 expressing T cell line, C8166-CCR5 cells. Several days after co-transfection, an R5-tropic HIV-1mt named MN38 strain was collected. We analyzed the co-receptor usage of MN38 and monitored its replication capability in CM PBMCs. We further analyzed the replication property of MN38 in monkeys having TRIM5αp.

**Results:** MN38 virus showed CCR5-tropism and replicated well in CM PBMCs. In monkeys, MN38 induced viremia, with plasma viral loads reaching a peak at 2-3 weeks post infection and ranging from 1.5x10⁴ to 1.0x10⁵ copies/ml. While the viremia became undetectable at 8 weeks post infection, administration of anti-CD8 monoclonal antibody into animals led to reappearance of viremia. In order to obtain monkey-adapted virus, we then inoculated plasma and whole blood of MN38-infected animals into one naive monkey. The inoculated virus stock was named MN38P1. MN38P1 replicated well in the
recipient monkey and established persistent viremia. We further performed the 2nd round of adaptation. The virus stock named MN38P2 was inoculated into two naïve CM. We observed an increase in levels of acute viremia, reaching 10^6 copies/ml in these animals.

**Conclusions:** We successfully obtained a monkey-adapted R5-HIV-1mt strain. This virus was found to induce persistent viremia in CM for at least 20 weeks. This combination of MN38-related strains and CM will encourage us to develop pre-clinical animal model of HIV-1 infection. We are still following up on the possibility of establishment of long-term persist infection. Moreover, it will be of great interest to elucidate which viral mutations are responsible for adaptation in monkeys. To this end, we are now analyzing whole viral genome by using next generation sequencing method.

### 320 New SIVsmm Strains To Achieve Control of Virus Replication With Conventional ART in Rhesus Macaques

**Background:** There is a renewed enthusiasm for a “cure research” aimed at understanding the mechanisms of HIV-1 persistence and developing therapeutic strategies to reduce and ultimately eliminate viral reservoirs. Limitations of human clinical studies make it imperative to develop analogous and tractable animal models for cure research. However, a major limitation of animal use is that SIV infection in rhesus macaques (RMs) is more virulent than HIV-1 and very difficult to control with antiretroviral therapy (ART). We have identified new SIVsmm strains that are less virulent in RMs and more closely reproduce the pathogenesis of HIV-1. Our hypothesis was that these new strains can be more readily controlled with ART. Our goal was therefore to achieve control of SIV replication in RMs by employing conventional ART regimens.

**Methodology:** Nine RMs (MaMu A*01, B*08, B17 neg and Trim5α matched) were iv infected with a newly derived transmitted-founder infectious molecular clone of the SIVsmmFTq strain that was never adapted in vitro. At 65 days postinfection (dpi), ART was initiated in four RMs (PMPA, 20 mg/kg/day; FTC, 40 mg/kg/day; integrase inhibitor L870812, 20 mg/kg bid). ART impact on viral replication was assessed by measuring plasma viral load (VL), as well as monitoring the memory CD4+ T cells in the intestine, the levels of T cell immune activation and proliferation, and biomarkers associated with disease progression in RMs: C-reactive protein, D-dimer, IL-6 and sCD14.

**Results:** All RMs become persistently infected with SIVsmmFTq. VL peaked at 10 dpi at 7-8 logs/ml and reached a set-point of 4.2-5.4 logs/ml by 42 dpi. After initiation of ART, VL decreased by 1.5-2 logs in 48 hours, followed by a slower decline to undetectable levels (<30 copies/ml) that were reached by 30 days post-treatment initiation. Over the next four months, VLs remained undetectable, without blips >30 copies/ml. Restoration of mucosal memory CD4+ T cells and reduction in immune activation was observed in RMs receiving ART but not in untreated controls. ART also normalized biomarkers associated with disease progression and mortality in RMs.

**Conclusions:** We established a robust macaque model of ART suppression with a three drug antiretroviral regimen that is analogous to current ART employed for HIV-1 infection. This simplified animal model of ART will permit evaluation of interventions targeting persistent viral reservoirs that are obstacles to a cure.

### 321 Immune-Pathogenesis/-Therapy of Persistent HIV-1 Infection in Humanized Mice

**Background:** The role of FoxP3+CD4+ Treg cells in HIV-1 diseases (aberrant immune activation) is poorly understood due to lack of a robust model. We have demonstrated that functional CD4+FoxP3+ natural Treg cells are developed in all lymphoid organs in humanized rag2−/-γC−/- DKO-hu HSC mice. These FoxP3+ Treg cells are preferentially infected and depleted by HIV-1. We discover that, while inhibiting IL-2 gene expression, FoxP3 enhances HIV-1 LTR expression in an NFkB-dependent fashion. FoxP3 silences the chromatin at the IL2 locus but activates it at the HIV-1 LTR.

**Methodology:** My laboratory studies development and function of the human immune system, as well as chronic human viral infection and immuno-pathogenesis. Treg cells are depleted during different stages of HIV-1 infection and during HAART treatment. HIV-1 replication, pathogenesis and HAART-reservoirs are investigated.

**Results:** When CD4+CD25+ Treg cells are depleted in vivo, acute HIV-1 infection is impaired, associated with enhanced immunity. However, when Treg cells are depleted during chronic infection, HIV-1 replication is enhanced with accelerated disease progression. When Treg was depleted during HAART, HIV-1 gene expression was induced from the HAART-resistant HIV-1 reservoir cells in various lymphoid organs. Therefore, FoxP3+ Treg cells can promote acute HIV-1 infection by suppressing anti-HIV immunity and by serving as target cells. During chronic HIV infection, however, Treg cells play an important role in suppressing immune activation and HIV-1 replication, contributing HIV-1 reservoirs during HAART.

**Conclusions:** Therefore, FoxP3+ Treg cells can promote acute HIV-1 infection by suppressing anti-HIV immunity and by serving as target cells. During chronic HIV infection, however, Treg cells play an important role in suppressing immune activation and HIV-1 replication, contributing HIV-1 reservoirs during HAART.
322  Dual Roles of Plasmacytoid Dendritic Cells in HIV-1 Infection and Pathogenesis
Guangming Li\textsuperscript{1}, Menglan Cheng\textsuperscript{2}, Jun-ichi Nunoya\textsuperscript{1}, Liang Cheng\textsuperscript{2}, Hailong Guo\textsuperscript{2}, Haisheng Yu\textsuperscript{1}, Yong-jun Liu\textsuperscript{2}, Liguo Zhang\textsuperscript{2}, Lishan Su\textsuperscript{2}
\textsuperscript{1}University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, \textsuperscript{2}Institute of Biophysics, Chinese Academy of Sciences, Beijing, China, \textsuperscript{3}Baylor Research Institute, Dallas, TX, United States

**Background:** Plasmacytoid dendritic cells are potent type I interferon producing cells and crucial for controlling various viral infection. However, the contribution of pDC in HIV-1 infection and pathogenesis remains controversial. On one hand, pDC have been shown to inhibit HIV-1 replication through their IFN-I production. The numerical and functional decline of pDC in HIV-1 infected patients correlates with opportunistic infection independent of CD4+ T-cell counts. On the other hand, pDC may contribute to HIV immunopathogenesis. The sustained pDC activation and IFN-I production in HIV-1 infected patients does not correlate with viral control but is predictive of disease progression. Additionally, pDC activation is rapidly controlled in the nonpathogenic SIV infection, whereas its activation and IFN-I production sustain during pathogenic infection in Asian monkeys. These reports highlight the importance of studying the interaction between HIV and pDCs.

**Methodology:** A monoclonal antibody specific to blood dendritic cell antigen-2, 15B, was used to deplete pDCs from humanized mice model through intraperitoneal injection. For acute HIV-1 infection, humanized mice were injected three times with 15B on -5, -3 and -1 days before infection, and mice were terminated at 8 days post-infection. For chronic HIV-1 infection, 15B was applied to mice at 11 weeks post-infection by injecting twice every week for 10 weeks. Mice were killed at 21 weeks post-infection.

**Results:** The expression of type I interferons and interferon stimulated genes are severely impaired by pDC ablation either before or during chronic HIV-1 infection. HIV-1 replication was significantly upregulated in pDC-depleted mice. However, HIV-1 induced depletion of human immune cells including T cells and total human leukocytes was reduced in spite of the increased viral replication.

**Conclusions:** pDC play a role not only in suppressing HIV-1 infection but also in promoting HIV-1 induced pathogenesis. These findings suggest that pDC depletion or suppression will provide a novel approach for HIV-1 therapy.

323  Characterizing the Acute Spread of Cell-Associated HIV in Humanized Mice
Kenneth M. Law, Alice W. Yewdall, Benjamin K. Chen
Infectious Disease, Icahn School of Medicine at Mount Sinai, New York, NY, United States

**Background:** The direct spread of HIV from one cell to another has been shown to be a prominent mode of infection in vitro. The extent which cell-to-cell infection operates in vivo, where the spatial organization and dynamic of cell-cell contacts is likely to be drastically different, has yet to be examined. This led us to investigate the mechanisms of HIV dissemination in vivo comparing cell-free viral inoculums with the injection of HIV-infected cells and following the initial round of infection in humanized mouse models that support HIV replication.

**Methodology:** We performed bioluminescence whole body imaging allowing us to visualize the trafficking patterns of adoptively transferred CD4+ T cells that were infected with infectious gaussia luciferase-expressing (NL-Gluc) HIV. To examine the efficiency with which cells become co-infected in vivo, we utilized a dual virus infection strategy whereby two infectious fluorescent HIV R5 tropic variants (NL-GlucI or NL-CI) are simultaneously introduced into mice and the numbers of singly infected and doubly infected cells were detected by flow cytometry and two photon imaging. We measured how efficiently the two viruses are co-transmitted by cell-to-cell transmission in vivo, when CD4+ T cells coinfected with NL-GlucI (green) and NL-CI (red), are used as donors that are intravenously injected into humanized mice.

**Results:** The lung of hu-mice is the first site where adoptively transferred NL-GlucI-infected CD4+ T cells that were infected with infectious gaussia luciferase-expressing (NL-Gluc) HIV. To examine the efficiency with which cells become co-infected in vivo, we utilized a dual virus infection strategy whereby two infectious fluorescent HIV R5 tropic variants (NL-GlucI or NL-CI) are simultaneously introduced into mice and the numbers of singly infected and doubly infected cells were detected by flow cytometry and two photon imaging. We measured how efficiently the two viruses are co-transmitted by cell-to-cell transmission in vivo, when CD4+ T cells coinfected with NL-GlucI (green) and NL-CI (red), are used as donors that are intravenously injected into humanized mice.

**Conclusions:** Using two humanized mouse models, we observed that spread of cell-associated HIV is efficient in vivo after intravenous exposure. We find that infected cells traffic initially to the lung where replication occurs. In addition, inheritance of multiple copies of HIV indirectly shows that infection of target cells may occur through VS. The frequent coinheritance of two fluorescent virus species in vivo, may be explained by a high frequency of cotransmission through VS. The results suggest that HIV dissemination in vivo can be driven by lymphocyte migration of cell associated virus.

Non-Pathogenic vs Pathogenic Hosts

324  Differential TCR Activation and TRAIL Regulation in Sooty Mangabeys and Rhesus Macaques
Shan Yu\textsuperscript{1}, Kenneth Rogers\textsuperscript{1}, Francois Villinger\textsuperscript{2}, Amitinder Kaur\textsuperscript{3}
\textsuperscript{1}Division of Immunology, Harvard Medical School, Southborough, MA, United States, \textsuperscript{2}Division of Pathology, Emory University, Atlanta, GA, United States, \textsuperscript{3}Harvard Medical School, Southborough, MA, United States

**Background:** We have previously shown that SIV infection resulted in increased CD4+ T lymphocyte apoptosis and elevated plasma tumor necrosis-receptor associated apoptosis-inducing ligand (TRAIL) in rhesus macaques (RM) but not sooty mangabeys (SM). We therefore investigated the relationship between T cell activation and TRAIL upregulation in SM and RM in vitro.
Methodology: PBMC from SIV-negative SM (n=15), SIV-negative RM (n=18), naturally SIV-infected SM (n=20), and SIVmac239-infected RM (n=7) were cultured for up to 24 hours with plate-bound anti-CD3 and anti-CD28 and monitored for direct and indirect effects of T cell receptor (TCR) signaling. T and non-T lymphocyte subsets were evaluated for activation, apoptosis and TRAIL upregulation by flow cytometry and cell supernatant for cytokines by multiplex luminex assays. Anti-TRAIL antibody and recombinant macaque soluble death receptor 5 were used for in vitro TRAIL-blocking experiments.

Results: TCR cross-linking resulted in rapid T cell activation and a significant increase in surface TRAIL expression on T and NK cells of both RM and SM. However, the magnitude of TRAIL increase was significantly higher in SM compared to RM and was not associated with increased apoptosis. Of interest, while T cell upregulation of CD69 expression was comparable in SM and RM, the production of T-derived cytokines IFNγ, IL-2, TNFα, IL-17, MIP-1α, and IL-5 was significantly higher in SM compared to RM. Exogenous addition of IL-2, IL-7, IL-15 and IL-21 induced a dose-dependent increase in TCR activation-induced NK TRAIL in RM, but the levels did not reach the magnitude seen in SM. Furthermore, in vitro inhibition of TRAIL decreased SM T cell activation suggesting that T cell-associated TRAIL may have co-stimulatory function. Following SIV infection, RM CD8+ T cells showed a significant decrease in TCR activation-induced TRAIL expression, while TRAIL upregulation was significantly increased in CD8+ T cells from SIV-infected SM. In contrast to TRAIL expression on T cells, SIV-infected RM but not SIV-infected SM showed a significant increase in TRAIL induction on pDC and mDC.

Conclusions: While mDC-associated TRAIL has been implicated in apoptosis, our data indicate a co-stimulatory function of T cell-associated TRAIL in SM. Disparities in induction of TRAIL on CD8+ T lymphocytes, NK cells and DCs in SM and RM, suggest that the dominance of non-apoptotic functions of TRAIL in SM may protect natural hosts against immunodeficiency and aberrant apoptosis.
RM DN T cells. Surprisingly, RM DN T cells showed closest similarity to CD8+ and not CD4+ T cells. TCR-stimulated SM DN T cells showed 2- to 580-fold upregulation of 31 genes including effector molecules and activation markers in contrast to up to 9-fold upregulation of only 15 genes in RM DN T cells. The genes showing greatest upregulation (>10-fold) in SM DN T cells included il22, il17a, ifng, tnf, il2, il4, il5 and il21, confirming their enhanced Th17, Th1 and Th2 functionality. Following SIV infection, profound DN T cell hypofunctionality was seen in SIV-infected RM but not SIV-infected SM.

Conclusions: Besides being significantly higher in frequency, SM DN T cells are functionally distinct from RM and may differ in their ontogeny. The diverse functional properties of SM DN T cells that are not affected by SIV infection likely play a role in regulating immune activation and preventing disease progression to AIDS in these natural hosts of SIV infection.

327 CD39/CD73/Adenosine Pathway in Progressive vs Non-Progressive Infections
Tianyu He1, Egidio Brocca-Cofano1, Cuiling Xu1, Jan Kristoff1, Samantha Ross1, Dongzhu Ma2, Charles R. Rinaldo3, Bernard J. C. Macatangay4, Cristian Apetrei1, Ivona Pandrea1
1Pathology, University of Pittsburgh, Pittsburgh, PA, United States; 2University of Pittsburgh, Pittsburgh, PA, United States; 3Microbiology and Molecular Genetics, University of Pittsburgh, Pittsburgh, PA, United States; 4Infectious Diseases and Microbiology, University of Pittsburgh, Pittsburgh, PA, United States

Background: The CD39/CD73/adenosine (ADO) pathway was associated with immunosuppression in multiple diseases; yet, its precise role in mediating immune activation and inflammation (IA/INF) during HIV-1/SIV infection remains unclear.

Methodology: We compared and contrasted the expression of markers related to either ADO production (CD39 and CD73) or ADO breakdown (CD26) on both regulatory (Tregs) and conventional T cells isolated from blood, lymph nodes (LNs), and intestine of nonprogressive (African green monkeys-AGMs) and progressive (pigtailed macaques-PTMs) models of SIVagm infection. Expression of ADO-related markers was assessed by flow cytometry during acute, early and late chronic infection, compared to preinfection levels and correlated with T cell immune activation (CD38/HLA-DR and Ki-67), monocyte activation (sCD14 and sCD163), and inflammation (CRP and proinflammatory cytokines).

Results: Baseline expression levels of both CD39 and CD73 on CD8+ Tregs isolated from blood and in CD4+ Tregs isolated from LNs and intestine were intrinsically high in AGMs. However, CD39, CD73 and CD26 expression remained at baseline levels throughout SIVagm infection in all the cells from different compartments of the AGMs, which control chronic IA/INF.

Conversely, in PTMs, which exhibit increasing IA/INF markers with disease progression, CD39 expression on circulating conventional T cells and Tregs significantly increased during the late stages of SIV infection. In the LNs, expression of both CD39 and CD73 was significantly increased on conventional T cells and Tregs, while only CD73 significantly increased after infection on Tregs in the intestine. In the LNs, a dramatic increase of CD26 expression on CD39 and CD73 cells occurred only during acute infection, while being maintained throughout infection in the intestine. Increased CD39 and CD73 expression in SIV-infected PTMs did not positively correlate with control of IA/INF.

Conclusions: CD39/CD73 expression on Tregs and T conventional cells undergo different dynamics among different lymphoid compartments and among different NHP species. Despite a higher baseline adenosine production in the AGM nonprogressive model, lack of variation of CD39/CD73 and CD26 markers suggest that ADO pathway is not critical for the control of IA/INF in AGMs. Conversely in the progressive SIV infection of PTMs, significant changes in CD39/CD73 and CD26 expression occur in tissues rather than blood, suggesting that future studies of the ADO pathway should focus on the tissue sites of viral replication. In pathogenic infections, increased CD39/CD73 expression and subsequent ADO production may be counteracted by the early increases in the expression of CD26, which is associated with adenosine deaminase.

328 Dynamics of B Cell Subpopulations in Pathogenic and Nonpathogenic SIV Infections
Egidio Brocca-Cofano1, Basile Siewe1, Dave Kurt1, Xu Cuiling1, Jan Kristoff1, Dongzhu Ma1, George S. Haret-Richter1, David C. Montefiori2, Alan LANDY2, Ivona Pandrea1, Cristian Apetrei3
1Pathology, University of Pittsburgh, Pittsburgh, PA, United States; 2Immunology and Microbiology, Rush University Medical Center, Chicago, IL, United States; 3Centre for Vaccine Research, University of Pittsburgh, Pittsburgh, PA, United States; 4Microbiology, University of Pittsburgh, Pittsburgh, PA, United States; 5Duke Human Vaccine Institute, Duke University, Durham, NC, United States

Background: We compared and contrasted the dynamics of B cell subpopulations in mononuclear cells from blood, lymph nodes (LN) and intestine (INT) in progressive SIV infection of pigtailed macaques (PTMs) and in non-progressive SIV infection of African green monkeys (AGMs) to elucidate the mechanisms of progression to AIDS in these natural hosts of SIV infection.

Methodology: We compared and contrasted the dynamics of B cell subpopulations in mononuclear cells from blood, lymph nodes (LNs), and intestine of nonprogressive (African green monkeys-AGMs) and progressive (pigtailed macaques-PTMs) models of SIVagm infection. Expression of ADO-related markers was assessed by flow cytometry during acute, early and late chronic infection, compared to preinfection levels and correlated with T cell immune activation (CD38/HLA-DR and Ki-67), monocyte activation (sCD14 and sCD163), and inflammation (CRP and proinflammatory cytokines).

Results: Baseline expression levels of both CD39 and CD73 on CD8+ Tregs isolated from blood and in CD4+ Tregs isolated from LNs and intestine were intrinsically high in AGMs. However, CD39, CD73 and CD26 expression remained at baseline levels throughout SIVagm infection in all the cells from different compartments of the AGMs, which control chronic IA/INF.

Conversely, in PTMs, which exhibit increasing IA/INF markers with disease progression, CD39 expression on circulating conventional T cells and Tregs significantly increased during the late stages of SIV infection. In the LNs, expression of both CD39 and CD73 was significantly increased on conventional T cells and Tregs, while only CD73 significantly increased after infection on Tregs in the intestine. In the LNs, a dramatic increase of CD26 expression on CD39 and CD73 cells occurred only during acute infection, while being maintained throughout infection in the intestine. Increased CD39 and CD73 expression in SIV-infected PTMs did not positively correlate with control of IA/INF.

Conclusions: CD39/CD73 expression on Tregs and T conventional cells undergo different dynamics among different lymphoid compartments and among different NHP species. Despite a higher baseline adenosine production in the AGM nonprogressive model, lack of variation of CD39/CD73 and CD26 markers suggest that ADO pathway is not critical for the control of IA/INF in AGMs. Conversely in the progressive SIV infection of PTMs, significant changes in CD39/CD73 and CD26 expression occur in tissues rather than blood, suggesting that future studies of the ADO pathway should focus on the tissue sites of viral replication. In pathogenic infections, increased CD39/CD73 expression and subsequent ADO production may be counteracted by the early increases in the expression of CD26, which is associated with adenosine deaminase.
neutralizing antibodies was similar in AGMs and PTMs, rapid progressor PTMs lacked the ability to develop anti-gp41. An increase in CD4+ T cells was observed in the LNs, especially in PTMs.

Conclusions: In AIDS-susceptible species, but not in non-progressive hosts, SIV infection is characterized by B cell dysfunction defined by loss of total and memory B cells, increased numbers of Bregs and increased B cell activation and apoptosis. These changes do not appear to be correlated with production of neutralizing antibodies, which is similar in both species. Yet, the rapid progressor infection is associated with a severe incapacity to mount an Ab response against gp41.

Compartmentalization

329 Transient Compartmentalization of SIV Variants in the Breast Milk of African Green Monkeys
Carrie Ho
Human Vaccine Institute, Duke University Medical Center, Durham, NC, United States

Background: In contrast to HIV-infected humans and SIV-infected rhesus monkeys, natural hosts of SIV, African green monkeys (AGMs), rarely transmit the virus postnatally. Previous studies in AGMs and rhesus monkeys revealed that breast milk populations of humans and rhesus monkeys are not genetically distinct from those in plasma. As the breast milk virus population of natural hosts of SIV remains uncharacterized, we sought to examine the genetic and functional diversity of breast milk SIV variants in this limited transmission setting.

Methodology: We intravenously infected six female hormone-induced lactating AGMs with the infectious molecule clone T/F SIV variant (SIVsab2018vTF). Single genome amplification and sequencing was performed on the env sequences of virus variants in milk and blood of AGMs at five months and one year post-infection. Maximum likelihood trees of plasma and milk env sequences were constructed using PAUP*, and compartmentalization of the milk env variants was assessed using the Slatkin-Maddison test. Finally, plasma and milk env genes were cloned and used to produce Env pseudoviruses for infectivity and neutralization sensitivity.

Results: The milk env variants in AGMs were largely compartmentalized from those in blood in four of five AGMs at five months post-infection. Notably, there was limited genetic diversity among milk virus variants as large numbers of identical sequences were observed among the milk virus lineages, suggesting clonal amplification of virus variants that seeded the breast milk compartment from blood. However, the milk virus lineages observed at five months post-infection did not persist at one year post-infection, and there was no signature env sequence or unique Env phenotype among milk virus variants. Furthermore, two of two plasma and one of two milk Env pseudoviruses from one monkey were functional, displaying similar infectivity in TZM-bl cells.

Conclusions: The compartmentalization of low diversity milk env variants in AGMs is transient and may be a result of the low number of CD4+ T lymphocyte target cells in the breast milk compartment of AGMs. This is in contrast with the limited compartmentalization previously observed in humans and rhesus monkeys. As there is a genetic bottleneck in postnatal virus transmission, the restricted diversity of milk virus variants and the limited number of CCR5-expressing CD4+ target cells in infant AGMs may together contribute to the rarity of postnatal transmission in natural hosts.

330 HIV Migrates Bi-Directionally Between Blood and Cerebrospinal Fluid and Between Blood and Semen
Antoine Chaillon1, Sara Gianella1, Joel O. Wertheim1, Sergei L. K. Pond1, Douglas D. Richman1, 3, Sanjay R. Mehta1, 3, David M. Smith1, 3
1Pathology, University of California San Diego, La Jolla, CA, United States; 2INSERM U966, Tours, France; 3Veterans Affairs San Diego Healthcare System, San Diego, CA, United States

Background: Once HIV infection is established, the virus persists in anatomical compartments, including the blood, central nervous system and genital tract. The dynamics of viral migration between these compartments remains poorly understood.

Methodology: We investigated partial HIV env sequences derived from paired cerebrospinal fluid (CSF) and blood samples from 11 ART-naïve, HIV-infected subjects and paired semen and blood samples from 4 subjects. Sequences were screened for hypermutation and duplication, aligned, and then analyzed by: (i) phylogenetic reconstruction using a Bayesian Markov-chain Monte Carlo approach, (ii) evaluation of viral compartmentalization using tree- and distance-based methods, and (iii) analysis of migration events using a discrete Bayesian asymmetric phylogeographic approach of diffusion with Markov jump counts estimation.

Results: Subjects were sampled longitudinally (range: 3-11 timepoints/subject) over a mean duration of 433 days (range: 9-2071 days). HIV-1 env sequences were isolated by clonal sequencing from blood plasma (range: 27-1520/subject), seminal plasma (21-85/subject) and CSF (11-59/subject). Mean env sequence length was 484 nucleotides (range: 333-648). The subjects had a mean CD4+ T-cell count of 541 cells/ml (range: 200-1123). Mean HIV RNA log10 copies/ml for blood plasma was 4.6 (range: 2.5-5.4), 3.4 for seminal plasma (2.5-4.0) and 3.8 for CSF (2.5-5.4). Compartmentalization was maintained throughout all sampled timepoints for 3 of the 4 individuals with paired blood and CSF samples but none of the subjects with paired blood and semen samples. We compared our Bayesian approach of inferred migration events with the Slatkin-Maddison test for compartmentalization, and the results were significantly correlated (Spearman R=0.61, p<0.01). We then estimated the direction of viral gene flow between compartments over time, and observed bi-directional replenishment of viral compartments. Specifically, there was a mean of 15 migration events from blood to semen (range 0-34) and 8 migration events from blood to CSF (range: 0-16). Considering migration towards blood, we observed 14 migration events from semen to blood (range 1-43) and 11 migration events from CSF to blood (1-15). Temporal analysis showed asynchronous peaks of viral migration to and from blood over time, suggesting transient disruption of viral compartmentalization.
Low Social Rank Prior To SIV or SHIV Infection Associates With Higher Viral Load in Chronic Infection

Gretchen N. Neigh1, 2, Timothy Hayes1, 2, Ronald Trible2, 3, Thomas H. Vanderford2, 3, Diane G. Carnathan2, 3, Constance S. Harrell2, Kirk Easley4, Mirko Paiardini2, 3, Guido Silvestri2, 3

1Physiology, Emory University, Atlanta, GA, United States, 2Yerkes National Primate Research Center, Atlanta, GA, United States, 3Emory University, Atlanta, GA, United States, 4Biostatistics, Emory University, Atlanta, GA, United States

Background: The tempo of disease progression in HIV-infected humans and SIV-infected macaques is quite variable among individuals, with high levels of virus replication predicting shorter survival. Prolonged exposure to stress may alter immune system function even in the absence of HIV or SIV infection, and disruptions in housing environment, a known stress stimulus, shorten survival time in SIV-infected macaques. Macaques housed in social groups establish a relatively stable matriarchal hierarchy. Within these hierarchies, subordinate animals consistently demonstrate elevated markers of chronic stress compared to dominant ones. In the current study we tested the hypothesis that stress history, as dictated by the subject’s social rank prior to study assignment, predicts viral load during chronic SIV infection.

Methodology: All rhesus macaques originated from social groups housed at Yerkes National Primate Research Center with established rank systems prior to study assignment. Macaques were stratified based on pre-infection social rank and then evaluated longitudinally throughout infection for viral load in plasma. We found that, in the acute phase of SIV or SHIV infection, the level of virus replication was not predicted by social rank prior to study assignment (p=0.37). Interestingly, in both early and late chronic phases of the infection, social rank prior to study assignment significantly influenced the level of virus replication (p=0.01 for subordinate vs. dominant/mid). In the early chronic phases of infection, copies of SIV RNA/ml of plasma in subordinate subjects (mean = 5.202 log10 copies/ml) was elevated compared to subjects that originated from dominant/mid ranks (mean = 4.888 log10 copies/ml). Also during late chronic infection, higher viral loads were observed in subordinate subjects (mean = 5.806 log10 copies/ml) compared to subjects from dominant/mid social ranks (mean = 4.213 log10 copies/ml).

Results: These results strongly suggest that HIV subpopulations migrate back and forth between blood and other anatomic compartments, and that viral populations in CSF and semen actively contribute to the contemporaneous HIV RNA population observed in the blood. These compartmental reservoirs may need to be targeted if eradication strategies are to be successful.

Pol Versus Env Genetics in SHIV-Infected Macaques Highlights Importance of Phylogenetic Signal

Chad Coomer1, Elizabeth M. Anderson1, Luke Smith1, Wei Shao1, Jonathan Spindler1, John W. Mellors2, John M. Coffin3, Zandrae Ambrose4, Mary F. Kearney1

1National Cancer Institute, NIH, Frederick, MD, United States, 2Division of Infectious Disease, Department of Medicine, University of Pittsburgh, Pittsburgh, PA, United States, 3Department of Molecular Biology and Microbiology, Tufts University, Boston, MA, United States, 4Division of Infectious Diseases, Department of Medicine, University of Pittsburgh, Pittsburgh, PA, United States

Background: Previously we investigated HIV pol populations in SHIV-infected macaques by single-genome sequencing to determine if low-level replication was a source of residual viremia during ART and to investigate viral compartmentalization across tissues. Using this approach, we found no evidence for evolution during suppressive ART and little evidence of viral compartmentalization. To investigate the possibility that the low diversity in pol masked the emergence of new viral variants and/or compartmentalization, we applied the same methods to the more diverse env gene in the infected macaques.

Methodology: Two macaques (M3250 and K02396) received 20 weeks of ART (TNF, FTC, EFV) and one macaque (6760) was untreated. Longitudinal plasma samples (N=11) from treated macaques were analyzed by single-genome sequencing of a 1 kb pol fragment and a 2.5 kb env fragment. In the untreated animal 6760, tissues were collected at necropsy after infection for 30 weeks of infection and single-genome sequences were obtained from PBMCs, lymph nodes, spleen, thymus, gut tissues, bone marrow, and lung. The entire 2.5kb env fragment and the 101 nucleotide V3 region alone were evaluated separately for population diversity, divergence, and compartmentalization using phylogenetic and panmixia analyses, and compared to results from pol.

Results: Previously we found diverse variants in pol but no new variants emerged in the plasma during suppressive ART, and viral population differences across tissues were due to varying frequencies of the same viral variants. Similarly, new phylogenetic and panmixia analyses of 2.5kb env sequences in plasma did not reveal the emergence of new variants during ART, showing that the lack of evolution in pol was not due to low phylogenetic signal in this region. Env populations analyzed in tissues from 6760 were highly diverse but showed similar population structures to pol and a lack of tissue compartmentalization. By contrast, phylogenetic analyses of only the V3 env region showed very weak phylogenetic signals and little diversity, indicating that the V3 region is not appropriate to evaluate intra-individual populations for diversity, evolution, and phylogenetic structure.

Conclusions: Comparisons of population genetics of pol and env in SHIV-infected macaques show that both regions have sufficient phylogenetic signal to assess evolution during ART and compartmentalization of virus populations. Although commonly used for genetic analyses, the V3 loop is under strong purifying selection that restricts its diversity and severely limits its usefulness for intra-individual analyses of viral genetics. These findings highlight the importance of performing single-genome and deep sequencing on regions of the viral genome with strong phylogenetic signal.
Modulation of Natural Killer Cell Activity by Simian Immunodeficiency Virus Peptides

Jamie L. Schafer1, Natasha Guha1, Nancy A. Wilson2, David T. Evans2
1Harvard University, Southborough, MA, United States, 2University of Wisconsin, Madison, WI, United States

Background: Natural killer (NK) cells recognize and kill virus-infected cells without prior antigenic stimulation. This recognition is achieved in part through the loss of interactions between inhibitory killer-cell immunoglobulin-like receptors (KIRs) on NK cells and their MHC class I ligands on virus-infected cells. MHC class I-bound peptides can affect NK cell activation by stabilizing or disrupting interactions with KIRs. We previously reported that the binding of a common MHC class I molecule in the rhesus macaque, Mamu-A*002 (A1*002), to an inhibitory KIR, Mamu-KIR3DL05 (3DL05), is stabilized by certain SIV peptides, but not by others.

Methodology: Using an A1*002-expressing, transporter-associated with antigen processing (TAP)-inhibited cell line pulsed with individual peptides, we evaluated 75 SIV peptides previously shown to bind to A1*002 (IC50<500 nM) for the ability to modulate the activity of primary 3DL05+ NK cells in cytotoxicity assays. Additional assays were also performed to identify peptide variants that differentially affect interactions with 3DL05 without altering binding to A1*002.

Results: We identified 26 SIV peptides that suppressed the cytolytic activity of 3DL05+ NK cells, three of which correspond to immunodominant CD8+ T cell epitopes that bind to A1*002 with a high affinity (IC50<10 nM), and are therefore likely to be among the most abundant epitopes presented on the surface of SIV-infected A1*002+ cells. An analysis of peptide variants revealed that substitutions at positions 7 or 8 could change a peptide that suppresses 3DL05+ NK cell activity into a peptide that does not, and vice versa, without affecting binding to A1*002. In competition assays, the suppressive peptide dominated to inhibit 3DL05+ NK cell activity when present at less than 2% of a mixture with a non-suppressive variant of the same peptide.

Conclusions: Our results demonstrate that viral peptides can modulate NK cell activation via KIR-MHC class I interactions. The dominance of suppressive peptides over non-suppressive peptides is consistent with the need to prevent NK cell activation in response to the complex repertoire of self peptides presented by MHC class I molecules on the surface of healthy cells. These observations also suggest that immunodeficiency viruses may acquire changes in epitopes that increase the avidity of MHC class I ligands for inhibitory KIRs as a mechanism of immune evasion to suppress the activation of certain NK cell subsets.

Rosuvastatin Reduces Immune Activation and Inflammation in Treated HIV Infection

Nicholas Funderberg1, Brian Clagett2, Ying Jiang2, Sara M. Debanne2, Norma Storer2, Danielle Labbato2, Steven Juchnowski2, Brian Ferrari2, Michael Lederman2, Grace A. McConsey2
1Health and Rehabilitation Sciences, The Ohio State University, Columbus, OH, United States, 2Case Western Reserve University/Case Medical Center, Cleveland, OH, United States

Background: Despite suppressive antiretroviral therapy (ART), elevated levels of immune activation and inflammation often persist in HIV-infected subjects. Statins have anti-inflammatory effects, and when given in combination with ART, may reduce immune activation.

Methodology: The 96-week Stopping Atherosclerosis and Treating Unhealthy bone with Rosuvastatin in HIV (SATURN-HIV) trial is a randomized, double-blind, placebo-controlled trial to evaluate the effect of rosuvastatin at week 48 on immune activation and inflammation. All subjects were on ART, and had HIV-1 RNA<1000 copies/mL, LDL-cholesterol <30mg/dL and evidence of immune activation (C8+CD38+DR+ >19% or hsCRP >2mg/L). Randomization was 1:1 to daily rosuvastatin 10 mg or placebo, and was stratified by protease inhibitor (PI) use. T cell activation was measured by expression of CD38, HLA-DR, and PD1. Monocyte activation was measured with soluble markers (sCD14 and sCD163) and by real time enumeration of monocyte subpopulations and tissue factor (TF) expression. We also measured markers of systemic inflammation (hsCRP, sTNF-RI and II, IL-6, IP-10, sVCAM-1 and ICAM-1), vascular inflammation (Lp-PLA2), and coagulation (D-dimer, fibrinogen).

Results: 147 subjects enrolled; 78% male, 70% black, 29% white, with median age 47 years and CD4 cells 613 cells/µL; 49% were on PI and 78% had HIV-1 RNA <50 copies/mL. Baseline characteristics were similar between groups, except for the % of CD14+CD16+ monocytes that expressed TF (statin = 21.8% and placebo = 18.9%, p=0.05). Rosuvastatin use reduced sCD14 (p=0.006), Lp-PLA2 (p=0.0007), and IP-10 (p=0.03) levels. In addition, sCD163 and fibrinogen decreased within the statin arm (p=0.001 and p=0.015). The %TF+ CD14+CD16+ monocytes was also reduced in the statin arm compared to the placebo arm (p=0.005). Within the statin arm, treatment reduced proportions of TF+ monocytes among all three subsets (CD14+CD16+, p=0.002, CD14+CD16+ and CD14+CD16+, p<0.0001 for both). There was also a greater decrease in the proportions of activated T cells between the placebo and statin arms (p=0.009 for CD4+ cells and p=0.003 for CD8+ cells).

Conclusions: 48 weeks of rosuvastatin treatment reduced significantly several markers of inflammation and lymphocyte and monocyte activation in ART-treated subjects, whether these favorable changes translate to a clinical benefit remains to be elucidated.
### Effects of Prednisolone On CD4 Counts and HIV Disease Progression: A Two-Year Clinical Trial

Christa Kasang, Samuel Kalluvya, Charles Majinge, Gilbert Kongola, Mathias Mlewa, Irene Massawe, R Kabyemera, K Magambo, H Klinker, E Koutsilieri, W Preiser, D Hofmann, J Hain, A Müller, Weissbrich, Albrecht Ulmer, Axel Rethwilm, August Stich, Carsten Scheller

1Institute of Virology and Immunobiology, University of Wuerzburg, Wuerzburg, Germany; 2Institute of Virology and Immunobiology, Bugando Medical Centre, Mwanza, United Republic of Tanzania; 3Bugando Medical Centre, Mwanza, United Republic of Tanzania

**Background:** HIV infection is associated with chronic immune activation, which may be a central mediator of HIV pathogenesis. Here we investigated the effect of the anti-inflammatory corticosteroid prednisolone on HIV disease progression.

**Methodology:** We conducted a randomized, double-blinded, placebo-controlled two-year clinical study in Tanzania to assess the effects of prednisolone on HIV disease progression in patients not yet eligible for antiretroviral therapy (HAART). A total of 326 HIV-infected patients were included in the study and randomly assigned to receive either 5 mg prednisolone per day or placebo for 24 months. Primary study end point was progression to an AIDS-defining condition or a drop of CD4 counts below 200 cells/μl, or death from any cause.

**Results:** Four patients receiving prednisolone and 11 patients receiving placebo developed an AIDS-defining condition (Fig. A) (P = 0.0196), and 16 and 18 patients respectively developed CD4 counts < 200 cells/μl. Average CD4 changes were +21.6 (± 4.4) cells/μl for prednisolone and -57.9 (± 8.9) cells/μl for placebo within two years (Fig. C). Prednisolone treatment was associated with a statistically significant increase in median HIV viral load between baseline and month 12 (1.7x10^4 copies/ml versus 3.7x10^4 copies/ml; p = 0.0247). Prednisolone-treated patients developed significantly fewer malaria episodes than placebo-treated patients (30 versus 60; P = 0.0016). No deaths occurred during the study.

**Conclusions:** This study demonstrates that a non-antiretroviral, immunomodulating substance is able to attenuate HIV disease progression. Our findings emphasize the role of immune activation in HIV pathogenesis and may stimulate studies with low-dose corticosteroids as an adjunct to HAART with the aim of reducing residual immune activation and long-term morbidity. The combination of HAART and prednisolone may also open a new strategy to prolong AIDS-free survival in resource-restricted settings. (clinicaltrials.gov NCT012999948)
337 Sevelamer Does Not Decrease Plasma LPS or sCD14 But Does Decrease Soluble Tissue Factor and LDL

Netanya G. Sandler1, Xinyan Zhang2, Ronald J. Bosch3, Nicholas T. Funderburk1, Janet K. Robinson4, Daniel C. Douek4, Cara C. Wilson5, Steven G. Deeks4, Michael M. Lederman1, Rajesh T. Gandhi7, for the A5296 Study Team

1Internal Medicine, University of Texas Medical Branch at Galveston, Galveston, TX, United States, 2Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, United States, 3Case Western Reserve University, Cleveland, OH, United States, 4NIADD Vaccine Research Center, National Institutes of Health, Bethesda, MD, United States, 5Internal Medicine, University of Colorado, Aurora, CO, United States, 6San Francisco General Hospital, San Francisco, CA, United States, 7Massachusetts General Hospital and Ragon Institute, Boston, MA, United States

Background: Inflammation is associated with increased morbidity and mortality in HIV-infected individuals. Microbial translocation may be a major driver of this inflammation. Sevelamer carbonate, a phosphate binder, decreases serum lipopolysaccharide (LPS), low-density lipoprotein (LDL) cholesterol, and inflammatory markers in hemodialysis patients. We hypothesized that sevelamer would reduce circulating LPS and monocyte and T cell activation in HIV-infected subjects.

Methodology: In this single arm study, HIV-infected participants not on antiretroviral therapy (ART) received sevelamer 1600 mg three times a day for 8 weeks and were followed for an additional 8 weeks off treatment. Circulating soluble CD14 (sCD14), LPS, IL-6, D-dimer, C-reactive protein (CRP), fetuin A, IL-1β, IP-10, soluble CD163 (sCD163), soluble tissue factor (sTF), and oxidized LDL (oxLDL) cholesterol were measured in centralized labs, and total, non-HDL, and LDL cholesterol at local research sites. HLA-DR+CD38+ and Ki67+ CD4 and CD8 T cells were measured by flow cytometry in a central lab. Statistical significance of changes in measurements between time points was determined using the sign test.

Results: 40 participants were enrolled; 4 were excluded from analysis because of missing key visits (n=3) or ART initiation (n=1). Of 36 evaluable participants, 72% were male; median age was 44 years; median CD4+ T cell count 585/mm3; median HIV-1 RNA 3800 copies/mL. Phosphate levels did not change significantly; 7 participants received phosphate supplementation per protocol due to serum phosphate <2.5 mg/dL; there were no other adverse events. Key results are shown in the table. LPS, sCD14, CD4+ T cell counts, and HIV-1 RNA levels did not change significantly with or after treatment. The frequency of HLA-DR+ CD4 T cells or Ki67+ CD4 or CD8 T cells or fetuin A, IL-1β, IP-10, or sCD163 levels did not change significantly during or after treatment.

Conclusions: In HIV-infected participants not on ART, sevelamer for 8 weeks does not appear to decrease microbial translocation or immune activation but appears to decrease LDL, oxLDL, and sTF. OxLDL induces TF expression in numerous cell types; sevelamer may reduce TF by decreasing OxLDL, suggesting that it might have beneficial cardiovascular effects. Further investigation into the effects of sevelamer on the coagulation cascade, including the biological relevance of the modest increase in D-dimer levels, is warranted.

338 Reduction of sCD163, SP and PD1+ Th Cell Levels in a Phase 1B Trial of the NK1R Antagonist Aprepitant

Pablo Tebas1, Serguei Spitsin2, Jeffrey Barrett3, Florin Tucu2, Okan Ecli3, James Korelitz4, Wayne Wagner1, Deborah Kim1, Renae Catalano3, Steven D. Douglas2

1University of Pennsylvania, Philadelphia, PA, United States, 2Children’s Hospital of Philadelphia Research Institute, Philadelphia, PA, United States, 3Westat, Rockville, MD, United States

Background: Substance P (SP) is an undecapeptide produced in neurons and immune cells and involved in nociception and inflammation. The effects of SP are mediated by the neurokinin 1 receptor (NK1R). Increased levels of SP are present in HIV-infected individuals and NK1R antagonists have anti-HIV effects in monocyte-derived macrophages in vitro, by decreasing the expression of CCR5. Aprepitant is an NK1R antagonist approved by FDA as an antiemetic. Increased plasma levels of sCD163 are associated with HIV disease progression.

Methodology: We conducted a phase IB randomized, placebo controlled, double blind study to evaluate the safety, antiviral activity, pharmacokinetics and immune modulatory effects of aprepitant in HIV infected adults not on antiretroviral therapy, with CD4+ cell count ≥ 350 cells/mm3 and plasma viral load ≥ 2,000 copies/ml. Subjects were stratified by viral load (< vs. ≥20,000 copies/ml) and randomized to receive aprepitant 375 mg QD or placebo for 14 days,
and followed for 42 days. Primary endpoints were Grade 2–4 adverse events (AE), change in viral load, plasma SP levels, cellular inflammatory markers and plasma sCD163 levels.

**Results:** Eighteen subjects were randomized (9 to aprepitant, and 9 to placebo): 72% male; 89% black; mean age 37 years. Median viral load (copies/ml) in log10 at baseline was 3.92 for aprepitant and 4.23 for placebo. There were no significant changes in plasma viremia during the dosing period: median (minimum, maximum) change in log10 viral load at day 14 was 0.03 (-0.32, 0.13) in the aprepitant arm and 0.02 (-0.10, 0.68) in the placebo (p = 0.83). There were no significant changes in cellular inflammatory markers CD4+ or CD8 CD38+/HLA-DR+ cells or in the frequency of CD4+/CCR5+ cells. Aprepitant was associated with significant decreases in percentages of CD4+ T-cells expressing PD-1 (30% to 21%, p = 0.04), plasma SP (-4.2 pg/mL, -10%, p = 0.05) and sCD163 (-503 ng/mL, -22%, p = 0.02), with no significant changes in the placebo arm. Mean peak aprepitant plasma concentrations on day 14 were 9.2 ± 3.6 μg/mL. There were no serious adverse events. Adverse events were equally frequent in both arms, mild and self-limited in nature. The use of aprepitant was associated with moderate increases in total and LDL cholesterol (+ 29 mg/dL, p = 0.01; 24 mg/dL p = 0.02 respectively), and increases in HDL cholesterol (4 mg/dL, p = 0.02).

**Conclusions:** Aprepitant was safe and well tolerated. At the dose used in this proof of concept phase IB study, aprepitant did not show significant antiviral activity, but its use was associated with decreased levels of CD4+ PD-1 cells, SP and sCD163 suggesting that blockade of the NK1R pathway may have a role in modulating monocyte activation in HIV infection. Prospective studies in virologically suppressed individuals are warranted.

### 339 Rifaximin Has Marginal Impact On Immune Activation in Immune Non-Responders To ART - ACTG 5286

Allan R. Tenorio1, Cara C. Wilson2, Ellen S. Chan3, Ronald J. Bosch4, Bernard J. Macatangay5, Suria Yesmin6, Sarah W. Read7, David M. Margolis8, Jeffrey M. Jacobson9, Alan L. Landay10

1Medicine, Rush University Medical Center, Chicago, IL, United States; 2Medicine, University of Colorado Health Sciences Center, Aurora, CO, United States; 3Center for Biostatistics in AIDS Research, Harvard School of Public Health, Boston, MA, United States; 4Center for Biostatistics Research in AIDS, Harvard School of Public Health, Boston, MA, United States; 5Medicine, University of Pittsburgh, Pittsburgh, PA, United States; 6Frontier Sciences, Amherst, NY, United States; 7Division of AIDS, National Institutes of Health, Bethesda, MD, United States; 8Medicine, University of North Carolina, Chapel Hill, NC, United States; 9Medicine, Drexel University, Philadelphia, PA, United States, 10Immunology and Microbiology, Rush University Medical Center, Chicago, IL, United States

**Background:** Immune activation (%CD38+ HLA-DR+ on CD8+ T-cells) predicts disease progression in untreated HIV-1 infection & CD4+ T-cell rise with ART. Immune activation is associated with elevated markers of gut microbial translocation (MT) from HIV-induced gut mucosal CD4+ T-cell depletion. HIV+ persons with CD4+ T-cell <350 cells/mm3 despite suppressive ART, immune non-responders, have higher levels of immune activation and MT. Rifaximin, a non-absorbable antibiotic, decreases plasma LPS in cirrhosis. We hypothesized that rifaximin would decrease gut MT & immune activation in immune non-responders.

**Methodology:** ACTG 5286 was a randomized, open-label 2-arm study of rifaximin. 73 HIV- adults on ART for ≥ 96 weeks with CD4+ T-cell < 350 cells/mm3 and viral load (VL) below assay limit for ≥ 48 weeks were randomized 2:1 to rifaximin 550 mg BID vs no study treatment for 4 weeks. %CD38/HLA-DR- and %Ki67+ on CD8+ T-cells, plasma LPS, sCD14, IL-6, D-dimer, sCD163 and sTNFR-II were measured at baseline & week 4; Wilcoxon rank-sum tests compared changes between arms.

**Results:** At entry, subjects had a median age of 51 years, and median baseline and nadir CD4+ T-cell of 223 and 40 cells/mm3, respectively. Compared to no treatment (n=22), rifaximin (n=43) for 4 weeks was associated with a significantly lesser increase in both %CD38+ HLA-DR+ of CD8+ T-cells [median change (Q1, Q3) in rifaximin: 0.0 (-1.7, 1.0) vs no treatment: 0.6 (0.1, 1.5); p = 0.028] and %Ki67+ of CD8+ T-cells [median change (Q1, Q3) in rifaximin: -0.1 (-0.3, 0.1) vs no treatment: 0.1 (-0.1, 0.3); p = 0.013], but not in other cellular markers of activation. Rifaximin use was not associated with a decline in plasma LPS [median fold-change (Q1, Q3) in rifaximin: 1.00 (0.83, 1.12) vs no treatment: 0.98 (0.91, 1.12); p = 0.45] or sCD14 [median fold-change (Q1, Q3) in rifaximin: 0.94 (0.85, 1.15) vs no treatment: 0.94 (0.89, 1.03); p = 0.97]. No significant differences between arms were identified in IL-6, D-dimer, sCD163 or sTNFR-II levels. Twenty-seven (55%) rifaximin-treated subjects reported a primary safety event (mostly grade 2); no grade 3/4 events were related to study treatment.

**Conclusions:** Rifaximin use for 4 weeks had a marginal impact on CD8+ T-cell activation, and was not associated with significant changes in levels of markers of gut MT, inflammation or coagulation. In HIV- individuals with incomplete CD4+ T-cell recovery despite suppressive ART, rifaximin was safe and well-tolerated.

### 340 Reduced Immune Activation During Tenofovir-Emtricitabine Therapy in HIV-Negative Individuals

Jose R. Castillo-Mancilla1, Annie Meditz1, Sharon Steffert1, Jia-Hua Zheng2, Becky J. Kerr3, Edward M. Gardner3, Brent E. Palmer4, Lane Bushman5, Samantha MaWhinney6, Peter L. Anderson2

1Infectious Diseases, University of Colorado, Aurora, CO, United States; 2Pharmaceutical Sciences, University of Colorado, Aurora, CO, United States; 3Infectious Diseases, Denver Health Hospital, Denver, CO, United States; 4Allergy and Immunology, University of Colorado, Aurora, CO, United States; 5Biostatistics and Informatics, University of Colorado, Aurora, CO, United States

**Background:** Higher levels of immune activation are associated with an increased risk of HIV acquisition. Previous research *in vitro* has identified immunomodulatory properties of tenofovir (TFV) in various cell lines. However, it is unknown whether TFV influences immune activation *in vivo*. We aimed to evaluate the effects of TFV therapy on cellular immune activation in HIV-negative individuals.

**Methodology:** HIV-negative adults received daily co-formulated tenofovir disoproxil fumarate (TDF) 300 mg/emtricitabine (FTC) 200 mg for 30 days followed by a 30 day washout period. Whole blood for flow cytometry was collected at baseline and on days 30 and 60. Immune activation was determined by measuring % HLA-DR and CD38 expression on CD4+ and CD8+ T-cells. Additionally, intracellular TFV-diphosphate (TFV-DP) was quantified in purified CD4+ and CD8+ T-cells, which were collected at one study visit in each participant. Immune activation data were log-transformed prior to analysis. Data were analyzed with one-way ANOVA for repeated measures and pairwise comparison for significant results between baseline, day 30 and day 60. The
relationship between immune activation and intracellular CD4+ and CD8+ TFV-DP was assessed using the Spearman correlation coefficient. A p value ≤0.05 was considered significant. Data are presented as geometric mean (95% CI).

Results: Data were available from 19 participants (10 female; 1 Hispanic; 9 African American). Co-expression of CD38/HLA-DR on CD4+ cells was reduced, but not significantly (ANOVA p = 0.29); baseline 2.61% (2.1 to 3.2), versus 2.11% (1.64 to 2.70) at day 30 (30 days of daily TDF-FTC), and 2.13% (1.64 to 2.76) at day 60 (30 days off drug). Significant differences for immune activation markers on CD8+ cells were demonstrated (ANOVA p = 0.02). Co-expression of CD38/HLA-DR on CD8+ cells was 3.97% (2.98 to 5.29) at baseline, 2.71% (2.01 to 3.66) at day 30, p = 0.03, and 2.46% (1.65 to 3.53) at day 60, p = 0.008. Differences between day 30 and day 60 were not significant (p = 0.58). No significant correlation was identified between CD38/HLA-DR expression and intracellular levels of TFV-DP in CD4+ (r = -0.18, 95% CI, -0.61 to 0.34; p = 0.51) or CD8+ (r = -0.01, 95% CI, -0.53 to 0.52; p = 0.97).

Conclusions: Exposure to TDF-RTC was associated with decreased immune activation in HIV-negative individuals. The effect endured for 30 days after drug discontinuation, which parallels the long half-life of intracellular TFV moieties. A decrease in immune activation could contribute to the known antiviral effect of TDF-RTC as pre-exposure prophylaxis (PrEP) in HIV-negative patients.

341 Mesalamine To Reduce Immune Activation During HIV Infection: A Randomized Controlled Trial
Ma Somsouk, Richard M. Dunham, Michelle Cohen, Rebecca Albright, Teri Liegler, Yuaner Wu, Jeffrey N. Martin, Priscilla Y. Hsue, Steven G. Deeks, Joseph M. McCune, Peter W. Hunt
University of California San Francisco, San Francisco, CA, United States

Background: Immune activation predicts morbidity and mortality in treated HIV infection and may contribute to persistent gut epithelial barrier defects and systemic microbial translocation. We hypothesized that the luminally active anti-inflammatory agent, mesalamine, might decrease mucosal inflammation in treated HIV infection, leading to decreases in microbial translocation and systemic immune activation.

Methodology: We performed a randomized placebo-controlled trial of mesalamine (Apriso) among HIV-infected individuals with incomplete CD4+ T cell recovery on suppressive antiretroviral therapy (ART). HIV-infected subjects with CD4 counts less than 350 cells/mm3 and undetectable plasma HIV RNA levels for greater than 1 year on ART were randomized to either mesalamine or placebo for 12 weeks followed by 12 weeks crossover to the other arm. Consenting subjects also participated in a serial rectal biopsy substudy. The primary outcome was the week 12 change in the percent of activated (CD38+ HLA-DR+) CD8+ T cells from baseline. Secondary outcome measures included changes in other immunologic markers in blood and gut as well as in markers of macro and microvascular function (flow-mediated dilatation [FMD] and hyperemic velocity).

Results: Of 33 subjects (24 in the rectal biopsy substudy), 15 were randomized to receive mesalamine and 18 placebo in the first 12 weeks. Compared to placebo-treated subjects, mesalamine-treated subjects experienced a similar median change in the percent of activated peripheral blood CD8+ T cells from baseline to week 12 (+0.9% vs. -0.4%, P = 0.63). There was also no evidence for a difference between groups in treatment-mediated changes in the percent of activated peripheral blood CD4+ T cells, rectal CD4+ and CD8+ T cells, or in plasma sCD14 (P = 0.14), IL-6 (P = 0.07), d-Dimer (P = 0.27), kynurenine to tryptophan ratio (P = 0.87), FMD, change in FMD or hyperemic velocity (P = 0.73), or rectal HIV RNA or DNA levels. There was also no evidence for a change in immunologic markers during mesalamine therapy when those with early vs. late therapy were combined.

Conclusions: Administration of a mesalamine preparation designed to release in the colonic mucosa does not significantly affect either systemic or colonic immune activation levels in HIV-infected individuals with incomplete CD4+ T cell recovery on suppressive ART. Alternative strategies to decrease microbial translocation and systemic immune activation are needed.

342 Decreased Levels of D-Dimer After Probiotic Supplementation in Patients Receiving ART
Birgitte Stiksrud, Piotr Nowak1, Dag Kvale1, Anders Thalme2, Stein-Erik Birkeland3, Anders Dahm1, Anne Ma Dyrhol Riise1, Marius Troseid4
1Oslo University Hospital, Oslo, Norway, 2Karolinska University Hospital, Stockholm, Sweden, 3TINE SA, Oslo, Norway

Background: Despite efficient antiretroviral treatment (ART) HIV-infected patients have increased morbidity and mortality compared to HIV seronegative individuals. Gut microbiota composition has potential impact on HIV pathogenesis and cardiovascular risk. Notably, markers of inflammation, coagulation and microbial translocation have been reported to predict all-cause mortality. The aim of this study was to assess the efficacy of probiotic supplementation in HIV-infected individuals.

Methodology: Randomized, placebo-controlled trial, completed study. Thirty HIV-infected patients on ART (median age 50.3y, 22 men, 22 Caucasians) were included. Inclusion criteria were: HIV RNA < 50 copies/ml, CD4 count < 500 cells/μl, no antibiotics or probiotics prescribed for the last 2 months, and no episodes of inflammatory bowel disease, immunomodulating therapy or infectious diarrhea for the last 6 months. Participants were randomized in a double blind fashion to the following study arms: i) probiotics (n=14), ii) placebo (n=8), and iii) controls (n=8). The probiotic consisted of 250 ml/day fermented skimmed milk supplemented with Bifidobacterium lactis, B. breve La-5 (107 cfu/ml). Heat-treated fermented skimmed milk served as placebo. The intervention period was 8 weeks. LPS was analyzed by Limulus Amebocyte Lysate colorimetric assay (LAL) (Lonza, USA), soluble (s) CD14 and IL-6 by ELISA (R&D Systems) and D-dimer was measured by Asserachrom kits (Diagnostica Stago, Asnière, France). Non-parametric statistics were applied.

Results: Of 33 subjects (24 in the rectal biopsy substudy), 15 were randomized to receive mesalamine and 18 placebo in the first 12 weeks. Compared to placebo-treated subjects, mesalamine-treated subjects experienced a similar median change in the percent of activated peripheral blood CD8+ T cells from baseline to week 12 (+0.9% vs. -0.4%, P = 0.63). There was also no evidence for a difference between groups in treatment-mediated changes in the percent of activated peripheral blood CD4+ T cells, rectal CD4+ and CD8+ T cells, or in plasma sCD14 (P = 0.14), IL-6 (P = 0.07), d-Dimer (P = 0.27), kynurenine to tryptophan ratio (P = 0.87), FMD, change in FMD or hyperemic velocity (P = 0.73), or rectal HIV RNA or DNA levels. There was also no evidence for a change in immunologic markers during mesalamine therapy when those with early vs. late therapy were combined.

Conclusions: Administration of a mesalamine preparation designed to release in the colonic mucosa does not significantly affect either systemic or colonic immune activation levels in HIV-infected individuals with incomplete CD4+ T cell recovery on suppressive ART. Alternative strategies to decrease microbial translocation and systemic immune activation are needed.

### 343 Immune Function and Viral Load Post AGS-004 Administration To Chronic HIV Subjects Undergoing STI

**Mark DeBenedette¹, Irina Tcherepanova², Alicia Gamble³, Joe Horatinovici, Jason Harris¹, Jean-Pierre Routy², Charles Nicolette⁴, AGS-004-001 Study Team**

1*Immunology, Argos Therapeutics, Durham, NC, United States, 2*McGill University Health Centre, Montreal, QC, Canada

**Background:** HIV infection induces immune dysregulation of both CD4 and CD8 T cell compartments. The anti-viral T cell pools in chronically infected patients are characterized by an exhausted activation phenotype, which is unable to control virus replication. ART can suppress HIV replication leading to stabilizing of CD4 T cell numbers and improving immune function. However, latent virus is not eliminated and the residual T cell pools do not overcome this state of T cell exhaustion. During non-controlled viral replication, the expression of Programmed Cell Death-1 (PD-1) on activated T cells is associated with T cell exhaustion and poor viral control. AGS-004 is a personalized dendritic cell (DC) loaded with RNA encoding autologous Gag, Nef, VPR, and Rev. AGS-004-001 is a Phase 2 trial designed to assess the efficacy and safety of AGS-004 during a 12 Week ART structured treatment interruption (STI) in chronic HIV-infected subjects. The goal of this immunotherapeutic intervention is to reverse this induction of T cell exhaustion leading to control of viral replication by inducing long-term immunity.

**Methodology:** Longitudinal blood draws where collected prior to AGS-004 dosing, after four doses of AGS-004 administered during ART, and after two doses during STI. Phenotype of HIV-specific CD4 and CD8 T cells and their proliferation capacity where determined by multi-color flow cytometry to determine the activation state of HIV specific T cells. Measurements of viral load were performed during these same time-frames. Associations between T cell proliferation, T cell activation state and viral control were determined.

**Results:** Positive changes in the magnitude of T cell proliferation to viral antigens after AGS-004 administration were detected in subjects with extended time to viral rebound during STI. Both activated CD4 and CD8 T cells lacking PD-1 where increased after AGS-004 administration in subjects with an extended time to viral rebound versus subjects with faster time to viral rebound measured during STI. Furthermore, subjects displaying rapid viral rebound had a greater number of exhausted CD57+/PD-1+ CD4 and CD8 effector T cells compared to subjects with an extended time to viral rebound.

**Conclusions:** Taken together, these data suggest that in study AGS-004-001 subjects with an extended time to viral rebound during STI demonstrated increases in CD4 and CD8 T cells with an activated phenotype. Furthermore, these same subjects displayed lower numbers of T cells expressing PD-1, a marker associated with dysfunctional CD4 and CD8 T cell activation. The role AGS-004 plays in the induction of an anti-HIV response geared towards delaying viral rebound during STI will be elucidated in the double blind placebo controlled phase 2 study AGS-004-003, currently underway.

### 344 Immunogenicity of AGS-004 Dendritic Cell Therapy in Patients Treated During Acute HIV Infection

**Cynthia L. Gay¹, Nancie Archin², Irina Tcherepanova², Esther Villiard³, Charles Hicks³, Mary Kearney³, John Coffin³, Mark DeBenedette³, Joseph Eron¹, Charles Nicolette², David M. Margolis¹**

¹Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 2Research and Development, Argos Therapeutics, Inc, Durham, NC, United States, 3Argos Therapeutics, Inc, Durham, NC, United States, 4Medicine, Duke University, Durham, NC, United States, 5Translational Research Unit, National Cancer Institute, Frederick, MD, United States, 6National Cancer Institute, Frederick, MD, United States

**Background:** Enhancing HIV-1 specific immunity without CD4 T cell activation may clear productively infected cells, a key aspect of eradication strategies. We assessed the safety and immunogenicity of AGS-004 dendritic cell (DC) therapy in patients initiating ART during acute HIV infection (AHI).

**Methodology:** In an open-label, single arm sub-study of AGS-004-003, DC therapy was administered to patients who initiated ART within 45 days of AHI (HIV RNA <50 c/ml for > 6 months). AHI was defined as a negative/indeterminate EIA or negative HIV RNA test within 45 days of detectable plasma HIV RNA. AGS-004 consists of matured autologous DCs co-electroporated with in vitro transcribed RNA encoding autologous HIV antigens (Gag, Vpr, Rev, and Nef) plus synthetically derived CD40 ligand RNA to achieve DC functionality. Patients received monthly doses of AGS-004 on ART following by measurement of immune responses after 3-4 doses (week 12 or 16). HIV RNA was measured at 4 time points by a single-copy assay (SCA). The frequency of resting CD4+ T-cell infection (RCI) was measured by quantitative viral outgrowth assay at baseline and after 3 doses (week 10) while on ART. Patients meeting a priori criteria for increased immune response after 3 doses were eligible for voluntary analytic treatment interruption (ATI) with continued monthly ART dosing. Criteria for restarting ART included CD4 count <350 cell/mm³, >20% decline in absolute CD4 count or percentage, or confirmed HIV RNA ≥10,000 c/ml.

**Results:** Since January 2012, 6 male patients were enrolled with median age 35 (range 26-56) and median baseline CD4 T cell counts 618 cells/mm³ (range 397-937). All six (100%) demonstrated positive immune responses defined as a ≥2-fold increase from baseline in the number of CD28+/CD45RA-CD8+ CTL that were also ≥3 standard deviations above the negative control. RCI was low in all 6 patients treated in AHI (0.043 to 0.767 infected resting CD4+ cells per million). Only one patient had a > 2-fold decrease in the frequency of RCI at week 10. HIV RNA by SCA was <1c/ml in 5 patients prior to ATI (6th pending). All 6 patients underwent ATI with a median duration of ART of 74 days (range 34-152). One participant with the lowest RCI (0.046 IUPM) had the longest ATI (152 days), and another is still in ATI (120 days). The patient whose RCI declined > 2-fold (from 0.179 to 0.067 IUPM) underwent ATI for 90 days. All 5 patients who restarted ART suppressed viremia. The few treatment-related adverse events were all grade 1.

**Conclusions:** Probiotic supplement significantly reduced D-dimer levels and possibly also levels of IL-6, both markers related to HIV-associated inflammation and cardiovascular disease. This reduction was apparently not related to changes in markers of microbial translocation. Additional studies to further elucidate mechanisms by which probiotics can influence upon gut microbiota, coagulation and inflammation are warranted.
Conclusions: AGS-004 DC therapy was safe, well-tolerated, and led to increased HIV-specific immune responses, but did not allow sustained ART interruption. However, this DC therapy might result in depletion of persistent HIV infection in ART-suppressed patients following administration of antilatency therapy.

345 Immunogenicity and VL Rebound After ATI in Chronic HIV Infected Patients Receiving MVA-B
Beatriz Mothe1, Miriam Rosas1, Montserrat Plana2, Nuria Climent1, Jose Luis Jimenez1, Judith Pich1, Mariano Esteban1, Felipe Garcia1, Christian Brander1
1IrsiCaixa AIDS Research Institute–HIVACAT, Badalona, Spain, 2Hospital Clinic–HIVACAT, IDIBAPS, University of Barcelona, Badalona, Spain, 3Hospital Gregorio Marañon, Madrid, Spain, 4Centro Nacional de Biotecnología, Madrid, Spain, 5Hospital Clinic–HIVACAT, IDIBAPS, University of Barcelona, Barcelona, Spain

Background: Poxvirus-based vaccines have shown great potential as HIV vaccines. We present the safety and immunogenicity results of a phase 1, double blinded, placebo-controlled therapeutic vaccine trial of an MVA vector expressing HIV-1 antigens from clade B (MVA-B) in successfully cART-treated HIV-infected patients who underwent cART interruption.

Methodology: Patients were randomly allocated to receive 3 intramuscular injections of MVA-B at 0, 4 and 16 weeks (n=20) or placebo (n=10). cART was discontinued in all patients 8 weeks after the last dose of MVA-B and viral rebound dynamics were assessed during the first 12 weeks of cART interruption. Immunogenicity to the vaccine insert was assessed using IFNγ ELISPOT.

Results: Vaccinations were well tolerated with no grade 3 or 4 side effects reported and VL was maintained below detectable levels in all patients while receiving MVA-B. No major changes in total magnitude or breadth of HIV-specific responses were detected between vaccinees and placebos. Only a minor significant increase in the responses targeting vaccine inserts of Gag and Env-gp120 was seen after 2 vaccinations and was maintained over time (median Gag responses of 290, 403 and 435 SFC/M PBMC at baseline, w6 and w24 respectively, p=0.02 and p=0.04). No increases of functional avidity after vaccination. Unspecific immune activation in vaccines (measured by EBV-specific responses in IFNγ ELISPOT) was ruled out. All patients rebounded after cART interruption. At week 12 after cART interruption, median reduction in VL (as compared to setpoint VL before any cART) was -0.24 vs -0.53 log copies/ml in MVA-B vs placebo, respectively (p=0.74). CD4 T cell counts declined similarly between groups. The dynamics of VL rebound did not correlate with the responses detected before cART interruption.

Conclusions: MVA-B vaccination was a safe strategy to increase Gag and Env-gp120 specific T cell responses in individuals with existing HIV-specific immunity but did not delay nor avoid viral load rebound after cART interruption.

346 Dynamics of VL Rebound After cART Interruption in HIV Patients Receiving MVA-B Plus Disulfiram
Beatriz Mothe1, Sonsoles Sanchez-Palomino1, Jose Luis Jimenez1, Jose M. Gata2, Bonaventura Clotet1, Mariano Esteban1, Montserrat Plana2, Juan Carlos Lopez Bernardo de Quiros1, Christian Brander1, Felipe Garcia2
1IrsiCaixa-HIVACAT, Hospital Germans Trias i Pujol, Badalona, Spain, 2Hospital Clinic-HIVACAT, IDIBAPS, University of Barcelona, Barcelona, Spain, 3Hospital Gregorio Marañon, Madrid, Spain, 4Centro Nacional de Biotecnología, Madrid, Spain

Background: In vitro data suggest that stimulation of HIV-1-specific T lymphocytes with a therapeutic vaccine could facilitate elimination of latent viral reservoir after virus reactivation with drugs (i.e disulfiram). We present the results of a substudy of a phase I, double blind placebo-controlled trial of an MVA-B therapeutic trial combined with disulfiram virus-reactivation treatment in successful cART-treated HIV-infected patients.

Methodology: Patients were randomly allocated to receive 3 intramuscular injections of MVA-B at 0, 4 and 16 weeks (n=20) or placebo (n=10). Twelve patients (8 MVA-B, 4 placebo vaccinated) received a 4th dose of MVA-B at week 36 followed by 2 months of disulfiram (250 mg qd). cART was discontinued in all 30 patients 8 weeks after the last dose of MVA-B and viral rebound dynamics were assessed during the first 12 weeks of cART interruption.

Results: VL was maintained below detectable levels in all patients while receiving MVA-B or MVA-B/disulfiram on ART but rebounded in all patients after cART interruption. The dynamics of VL rebound were not significantly different between the disulfiram treated/untreated groups. Proportion of patients with VL rebound at weeks 2 and 4 after cART interruption was similar between groups (w2: 7/12 (58%) and 8/16 (50%), w4: 11/12 (92%) and 15/17 (88%), in MVA-B/disulfiram vs MVA-B, P = 0.66 and 0.74), respectively). At week 12 after cART interruption, mean (SE) change VL (as compared with setpoint VL before any cART) was −0.72 (0.4) vs −0.35 (0.3) in MVA-B/ disulfiram vs MVA-B, respectively (P = 0.46). CD4 T cell counts declined similarly between groups after cART interruption.

Conclusions: A combination strategy of a therapeutic vaccine (MVA-B) plus disulfiram treatment neither prevented nor delayed viral load rebound after cART interruption as compared with MVA-B vaccination alone.

347 Vaccination With Autologous Dendritic Cells Pulsed With Autologous HIV-Infected Apoptotic Cells
Bernard J. Macatangay1, Sharon A. Riddler1, Nicole D. Wheeler1, Mary J. Buffy1, Aarika Yates1, LuAnn Borowsky1, Theresa L. Whiteside2, Charles R. Rinaldo3
1Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States, 2University of Pittsburgh Cancer Institute, Pittsburgh, PA, United States, 3Infectious Disease and Microbiology, University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA, United States

Background: We evaluated the safety, tolerability, and immunogenicity of a therapeutic HIV vaccine composed of autologous dendritic cells (DC) pulsed with autologous, inactivated, HIV-1 infected apoptotic cells (DC-HIV vaccine).

Methodology: Autologous HIV-1 was isolated from ART-naive subjects who then initiated PI-based ART. DC-HIV vaccine was composed of autologous monocyte-derived DC (matured with TNF-α, IL-1β, IFNγ, Poly I:C) pulsed with autologous lymphocytes infected with autologous HIV-1 and inactivated by UV/psoralen. After virologic suppression (<50 cps/mL) for at least 12 weeks, subjects received 3 doses (101 DC each) of DC-HIV vaccine subcutaneously, given at 2 week intervals, followed 6 weeks later by analytic treatment interruption (ATI). A 4th HIV-DC vaccine dose was given 2 weeks into ATI. The
primary endpoint was change in HIV-1 RNA from pre-ART to 12 weeks after ATI. Polynuclear CD8+ T cell responses to the vaccine (n=7) and to consensus HIV-1 Gag peptide pools (n=10) were evaluated before and after vaccination. Changes in T cell immune activation (DR+CD38+) and regulatory T cell (Treg) and myeloid-derived suppressor cell (MDSC) frequencies were also assessed.

**Results:** Ten male subjects were enrolled and received study vaccine (pre-ART median CD4 = 486 cells/mm³ and HIV-1 RNA = 4.53 log₁₀ copies/mL; median duration of HIV diagnosis = 27 mos). The DC-HIV vaccine was well-tolerated and caused only minor local reactions. All subjects remained off ART for the 12-week ATI. Three of 10 subjects had a ≥0.4 log₁₀ decrease in HIV-1 RNA from their pre-ART baseline. CD8+ T cell polyfunctional response was increased in 3/7 subjects after ATI compared to the pre-vaccine response while on ART. Additionally, 4/10 subjects had an increase in CD8+ T cell polyfunctional response to Gag peptide but only 1/3 subjects with ≥0.4 log decrease in HIV-1 RNA had an increase in response to Gag peptide. There was an increase in CD4+ (p=0.006; Wilcoxon signed rank test) and CD8+ (p=0.007) T cell activation following the first vaccine dose but this returned to pre-vaccine baseline 6 weeks after the 3rd vaccine dose. No change in Treg frequency after vaccination was observed but MDSC frequency was increased (median=2.67-fold; P<0.006). MDSC frequencies remained increased through the 12-week ATI.

**Conclusions:** DC-HIV vaccination was safe and well tolerated, and associated with a decrease in plasma HIV-1 RNA in some subjects and an early and transient increase in both CD4+ and CD8+ T cell immune activation. Modest increases in CD8+ T cell anti-HIV-1 responses and a subsequent decrease of T cell activation to baseline levels may be related to enhanced frequencies of MDSCs induced by the DC vaccine.
Methodology: CoRSeq\textsubscript{B} B-HIV, C-HIV, D-HIV and AE-HIV algorithms were designed and tested using every respective phenotypically characterised patient-derived V3 sequence in the Los Alamos Database, and from our recently published studies. Unique sequences were randomly assigned to “design” and “test” sets for each subtype and analysed for phenotype specific characteristics.

Results: Analysis of “design” sets revealed differing V3 characteristics for CCR5- and CXCR4-using viruses, including charge, length, glycosylation and amino acid mutations, which informed CoRSeq\textsubscript{B} prediction criteria. CoRSeq\textsubscript{B} predictive accuracy was then tested against independent “test” sequences. We found that CoRSeq\textsubscript{B} algorithms have more favorable sensitivity and specificity profiles for predicting HIV-1 coreceptor usage than any alternative, including geno2pheno (Table).

Conclusions: Once clinically validated in future studies our highly sensitive and specific B-HIV, C-HIV, D-HIV and AE-HIV algorithms may enhance access to MVC and future coreceptor antagonists for countries where non-B HIV-1 strains predominate, and which have expanding economies and improving health care systems, such as India and China where C-HIV is endemic and Thailand, Indonesia and Vietnam where AE-HIV predominates. Developed nations with increasing AE-HIV prevalence such as Japan may also benefit from CoRSeq\textsubscript{AE}. CoRSeq\textsubscript{AE} has been developed as an online platform that will soon be freely available at www.burnet.edu.au/coreceptor.

Identification of Novel B*57:01 Restricted Peptides From HIV gp140 Using Immunopeptidomics

Sri H. Ramarathinam\textsuperscript{1}, Nadine L. Dudek\textsuperscript{1}, Robert J. Center\textsuperscript{2}, Damian F. J. Purcell\textsuperscript{2}, Anthony W. Purcell\textsuperscript{2}

\textsuperscript{1}Department of Biochemistry and Molecular Biology, Monash University, Clayton, Australia, \textsuperscript{2}Department of Microbiology and Immunology, University of Melbourne, Parkville, Australia

Background: A small fraction of HIV-infected patients known as “elite controllers” maintain very low levels of plasma HIV and near normal levels of CD4+ T-cells without antiretroviral therapy. The majority of these long-term non-progressors possess HLA alleles such as HLA-B*57:01 or -B*27:05 that are thought to offer superior T-cell mediated immunity. The majority of peptide epitopes presented by these protective haplotypes have been identified using synthetic peptide libraries and no systematic study has been performed to identify the T-cell epitopes naturally presented by these apparently protective alleles. The use of synthetic peptides may fail to identify post-translationally modified epitopes, epitopes of non-canonical lengths and those arising from translation of alternative reading frames. We have used a mass spectrometry-based immunopeptidomics approach to identify the peptides naturally presented by protective alleles.

Methodology: HLA class I molecules were immunoaffinity purified from cells transfected with plasmids expressing HLA B*57:01 and HIV Env gp140, Rev and Vpu. HLA- bound peptide cargo was separated using reversed-phase chromatography and analyzed on a high resolution AB SCIEX 5600plusTriplTOF mass spectrometer. The data obtained was searched using ProteinPilot software. Peptide assignments were rigorously curated and validated with isotopically labeled HIV peptides.

Results: Over 2900 B*57:01-restricted human peptides were identified and we confirmed ten B*57:01 restricted, naturally presented HIV-gp140 peptides using synthetic peptides. Six of these peptides form part of a larger immunogenic region that was assigned on the LANL-HIV Epitope database. One of the four peptides is part of the Env signal peptide and has a post-translationally modified tryptophan residue. Additionally, one Rev peptide was identified and there were no peptides representing Vpu.
**Conclusions:** Using a cutting-edge immunopeptidomics approach we have identified novel epitopes that are non-conventional or post-translationally modified. Our methodology has enabled the identification of one of the largest sets of naturally presented human B*57:01 epitopes reported to date along with several novel B*57:01-restricted HIV peptides, setting the stage for elucidation of epitopes from other HIV proteins and analysis of T-cell responses.

**351 New Summaries and Computational Tools at Los Alamos HIV Immunology Database**

**Karina Yusim**, Shihi Feng1, Hyejin Yoon1, KumKum Ganguly1, Jennifer Macke1, James Szinger1, Anthony P. West1, Pamela Bjorkman2, Brian Foley1, Bette T. Korber1

1HIV Database, T-6, Los Alamos National Laboratory, Los Alamos, NM, United States; 2California Institute of Technology, Pasadena, CA, United States

**Background:** Los Alamos HIV immunology database is an annotated, searchable inventory of more than 17,000 of entries of HIV-1 cytotoxic and helper T-cell epitopes and antibody binding sites, integrated with the sequence variability data from the HIV Sequence Database. The database is extensively used and is being cited in major publications on HIV. We strive to provide latest information, summaries and tools for the HIV field, and considering the literal explosion of HIV antibody research in the recent years, several global and useful computational tools are being added to the database to assist researchers worldwide.

**Methodology:** We used the vast body of information available in the database as well as extra extensive literature searches and analysis to launch new summary tables and analysis tools.

**Results:** We are introducing 3 new important resources. (i) New "Neutralizing Antibody Resources" page provides searchable summaries of broadly neutralizing HIV-1 antibodies, with links to papers, Ab sequences and structure, notes on breadth of neutralization, where to find Ab contacts or key residues, and heavy and light chain composition; exact coordinates of important neutralizing antibody binding sites and other HIV-1 Env features. (ii) To help systematize the diverse and ambiguous naming systems in different studies both for the new antibodies and the viruses used in large neutralization panels, we put together a relational database of HIV sequences, antibodies and neutralization data from these studies with an easy one-to-one correspondence between the various short names, database names and accession numbers, thereby simplifying analysis for many researchers, and meta-studies in particular. (iii) Finally, the new global HIV genome browser tool is being released in the database. This tool retrieves and summarizes the vast and diverse information and tools available at HIV Immunology database. The browser allows users to look at the whole HIV genome as well as to zoom in to every HIV genome position or a region of interest and visualize all information we have in the database about this position (overlapping epitopes, antibody binding sites, antibody contact residues, functional domains, HIV sequence variability, database alignments etc). This tool also provides links to the database annotation and database tools, as well as pubmed and other sources.

**Conclusions:** The new summaries and tools developed in HIV Immunology database provide a user-friendly one-stop source of information about HIV genome and immunological data and promise to be very useful for HIV scientific community and for vaccine design efforts.

**352 Identification of Pattern Recognition Receptor for HIV-1 in Human Dendritic Cells**

Sunnie M. Yoh1, Monika Schneider1, Stephen Soonthornvachartri, Kevin Olivier1, Sourav Bandypadhyay2, Elisa Decastro3, Addifo G. Sastro3, Sunit K. Chanda3

1Inflammatory Diseases, Sanford Burnham Medical Institute, La Jolla, CA, United States; 2Helen Diller Family Comprehensive Cancer Center, University of California San Francisco, San Francisco, CA, United States; 3Department of Microbiology, Mount Sinai School of Medicine, New York, NY, United States

**Background:** In attempt to identify putative intracellular pattern recognition receptors (PRRs) which recognize HIV-1 viral nucleic acids and trigger IFN mediated immune responses, we set up a si-RNA screen in MDDC cells where infection with Vsvg pseudotyped HIV-1 virus in the presence of VLP-Vpx particle induces ISG 54 expression.

**Methodology:** Targeted library of si-RNAs with known nucleotide binding domain and/or involvement in nucleotide metabolism are screened for inhibition on the infection mediated ISG54 induction. A knock-down efficiency of 70–90%, independent of donors, was achieved in MDDCs with transient transfection of si-RNAs. Further more, the ISG54 induction was IRF3 dependent and but independent of NFkB, p65 and the infection mediated induction was restricted to ISGs since pro-inflammatory cytokines such as TNFalpha and IkB are not induced. Initial hits were subjected to rigorous reconfirmation and deconvolution of pooled siRNAs for each hit gene as well as validation for their ability to enhance ISRE-reporter in 293T upon cDNA over-expression.

**Results:** Currently, we have several protocols that regulate innate responses in MDDCs to HIV-1 infection, and these factors are being characterized to determine if they play a direct role as a pattern recognition receptor to HIV-1.

**Conclusions:** Identification of PRR specific for HIV-1 virus will be a profound step in understanding innate response, or lack of the responses, upon HIV-1 infection.

**353 Plasmacytoid Dendritic Cell Phagocytosis of IgG Anti-p24 Associates With Control of HIV Infection**

Christian Tjian3, James Taylor1, Mazmah A. Morshidi1, Jeffrey N. Martin1, Steven G. Deeks2, Dino Tani3, Silva Lee3, Sonia Fernandez1, Martyn A. French1

1School of Pathology and Laboratory Medicine, University of Western Australia, Perth, Australia; 2School of Medicine, University California San Francisco, San Francisco, CA, United States; 3lung Institute of Western Australia, University of Western Australia, Perth, Australia

**Background:** Defining immune control mechanisms in patients with HIV infection will facilitate the development of HIV vaccines. Slower progression of HIV infection is associated with IgG antibodies to HIV Gag proteins. We have investigated this association by comparing functional characteristics of IgG antibodies to HIV p24, particularly phagocytosis by a plasmacytoid dendritic cell (pDC) cell line and the relationship with antibody isotype diversification, in HIV controllers and non-controllers.
**Methodology:** Sera from 59 HIV controllers (30 elite and 29 viremic) and 30 non-controllers were obtained from members of the SCOPE cohort. Phagocytic antibodies to HIV p24 (recombinant, baculovirus) were assayed using the Gen2.2 cell line, which we have shown to mediate phagocytosis via FcγRIIa. IgG1 (upstream) and IgG2 (downstream) antibodies to native HIV p24 were assayed by ELISA.

**Results:** Phagocytic antibodies against HIV p24 were higher in viremic controllers (p=0.0001) and, to a lesser extent, elite controllers (p=0.05) than non-controllers but did not correlate with plasma HIV RNA levels or CD4+ T cell counts in viremic controllers. Both IgG1 and IgG2 antibodies to HIV p24 were detected in all patient groups and correlated strongly (r=0.63, p<0.0001). However, the antibody response was skewed away from IgG2 in non-controllers compared with controllers. Viremic controllers, but not elite controllers, exhibited higher serum levels of IgG1 and IgG2 anti-p24 than non-controllers (p=0.004 and 0.0004, respectively). Phagocytic antibodies against HIV p24 correlated with IgG1 and IgG2 anti-p24 (r=0.75 and 0.61, respectively; p<0.0001 for both). Neither IgG1 nor IgG2 anti-p24 correlated with plasma HIV RNA levels in viremic controllers or non-controllers but both correlated negatively with CD4+ T cell counts in viremic controllers (r=-0.33, p=0.08 and r=-0.49, p=0.0007, respectively).

**Conclusions:** Phagocytic antibodies (using a pDC cell line) and IgG1 and IgG2 antibodies to HIV p24 were higher in viremic controllers, but not elite controllers, compared with non-controllers. IgG antibodies to HIV p24 may, therefore, contribute to, or at least be a marker of, immune control mechanisms in HIV controllers who cannot achieve elite control. These antibodies might activate anti-viral accessory cell responses, such as those mediated by pDCs.

### 354 Recruitment of Functionally Different NK Cells To the Rectal Mucosa in Vaccinated Macaques

**Namal P. M. Liyanage1**, Shari N. Gordon1, Monica Vaccari1, Poornam Pego2, Melvin Doster1, David Venzon1, James Tartaglia2, Susan W. Barnett3, Nelson Michael4, Genoveffa Franchini5

1National Cancer Institute, National Institutes of Heath, Bethesda, MD, United States; 2Department of Research and Development, Sanofi Pasteur, Swiftwater, PA, United States; 345 Sidney Street, Novartis Vaccines & Diagnostics, Cambridge, MA, United States; 4U.S. Military HIV Research Program, Rockville, MD, United States

**Background:** Increasing evidence suggest that HIV can be controlled by Natural Killer cells (NK cells), via multiple mechanisms including antibody dependent cellular cytotoxicity (ADCC). In the RV144 vaccine trial, that showed 31% protection from HIV acquisition, there was an inverse correlation between risk of infection and ADCC, suggesting the importance of NK cells. NKG2A+ NK cells express CD16 and mediate ADCC. Mucosal Nkp44+ NK cells produce IL-17 and IL-22 are important for the homeostasis of mucosal compartments. Here we investigated whether the ALVAC/SIV gp120 vaccine regimen adjuvanted with ALUM or MF59 could affect vaccine efficacy and NK cell function in mucosa.

**Methodology:** Two macaque cohorts were vaccinated with ALVAC-SIV gp120 vaccines. One group was boosted with the gp120 protein, adjuvanted with ALUM (n=27) while the other group was given the gp120 formulated with MF59 (n=27). All the animals were challenged with low repeated dose of SIVmac251 intra-rectally. Rectal biopsies were analyzed at one week after the last immunization for the frequency and function of NK cells by flow cytometry.

**Results:** We observed a significant protection from SIVmac251 acquisition versus the 47 control animals in the ALUM but not in the MF59 group. Both vaccines recruited NKG2A+ and Nkp44+ NK cells to the gut. However, the frequency of NKG2A+CD107a+ NK cells and NKG2A+TNFα+ NK cells were significantly higher in the MF59 group (p=0.015, P=0.0468) following stimulated with PMA/Ionomycin whereas the Nkp44+IL17+ NK cells were significantly higher in the ALUM group when stimulated with SIV env peptides (p=0.0098).

**Conclusions:** Our results indicate that vaccination with ALUM recruits regulatory Nkp44+IL17+ NK cells whereas vaccination with MF59 was associated with a higher recruitment of cytotoxic NKG2A+CD107a+ NK cell subsets to the gut. However, none of the differences correlated with protection from SIV mac251 acquisition.

### 355 HIV Myeloid-Derived Suppressor Cells Inhibit the Protective Response To Cytomegalovirus

Ankita Garg1, Stephen A. Spector1, 2

1Pediatrics, University of California San Diego, La Jolla, CA, United States; 2Rady Children’s Hospital, San Diego, CA, United States

**Background:** HIV infection is associated with diminished protective responses against opportunistic infections including cytomegalovirus (CMV). In this study, we examined the effect of HIV expanded myeloid derived suppressor cells (MDSCs) on CMV specific effector cells.

**Methodology:** Peripheral blood mononuclear cells (PBMCs) obtained from HIV seronegative, CMV seropositive healthy donors were cultured in presence of heat inactive HIV BaL. After 5 days, cells were stained with anti-CD11b, anti-CD33, anti-CD14 and anti-HLA DR. CD11b+CD33+CD14+HLA DRhi (DRhi monocytes) and CD11b+CD33+CD14+HLA DRlo (MDSCs) cell subsets were sorted using flow cytometry. Sorted cell fractions were cultured with freshly isolated autologous PBMCs in presence or absence of a peptide pool of CMV pp65 antigen (1 µg/ml). IFNγ and IL-10 were determined by ELISPOT and expressed as spot forming units (SFU). Sorted cell fractions were cultured in presence of LPS (100 ng/ml) and IFNγ (2 ng/ml). IL-12p70 was determined in culture supernatants by ELISA and surface expression of HLA DR and CD83 (maturity markers) by flow cytometry. CD150 and B7H4 (leukocyte expressed as spot forming units (SFU). Sorted cell fractions were cultured in presence of LPS (100 ng/ml) and IFNγ.

**Results:** Culture of PBMCs with heat inactivated HIV resulted in a significant expansion of MDSCs as compared to control PBMCs (p=0.003). Expansion of MDSC and DR+ monocyte cell populations were comparable in the presence of HIV (p=0.74). PBMCs stimulated with the CMV pp65 peptide pool and cultured with sorted autologous MDSCs had fewer IFNγ SFU compared to PBMCs without MDSCs (p=0.03); however, PBMCs cultured with DR+ monocytes did not significantly differ (p=0.37). Furthermore, pp65 stimulated PBMCs produced increased IL-10 SFU when cultured with MDSCs compared to cultures with the DR+ monocyte subset. The MDSC subset exhibited a 2-fold increase in expression of surface CD150 and 1.3-fold increased expression of B7H4 as compared to the expression on the DR+ monocyte subset (p=0.03). HIV MDSCs maintained HLA DR+ and CD83+ expression as compared to the DR+ monocytes, even when cultured with LPS and IFNγ. Furthermore, these cells produced 4-fold less of the Th1 polarizing cytokine IL12p70 as compared to DR+ monocytes (p=0.02).
Conclusions: These findings suggest that HIV infection results in a significant expansion of MDSCs and that MDSCs are involved in suppression of the immune response directed against CMV. Understanding the mechanism(s) responsible for the suppressed immune response against CMV will assist in the development of treatment strategies designed to improve the immunity to CMV and other opportunistic infections associated with advanced HIV infection.

356 Induction of Gut Anti-HIV Immune Response via Dendritic Cell Targeted Intranasal Vaccination
Darren Ruane1, Yoonkyung Do1, Akash Greg1, Haekyung Lee1, Thomas Kraus2, Jordan Poles1, Lucas Brane1, Christine Trumpfheller1, Andres Salazar3, Ralph Steinman4, Saurabh Mehandru1

1Gastroenterology, Mt Sinai School of Medicine, New York, NY, United States; 2School of Nano-Bioscience and Chemical Engineering, Ulsan National Institute of Science and Technology, Korea, Republic of Korea; 3Mt Sinai School of Medicine, New York, NY, United States; 4Rockefeller University, New York, NY, United States; 5Oncovir, Inc, New York, NY, United States

Background: The mucosal surfaces of the gastrointestinal (GI) tract are preferentially targeted by HIV-1, resulting in profound depletion of GI CD4+ T cells and massive viral replication early in the course of infection. Therefore, the induction of an effective GI mucosal immune response is important for the HIV-1 vaccine effort. Here, we have employed a novel dendritic cell targeted vaccine strategy to induce GI mucosal immune responses to HIV gag p24 antigen.

Methodology: C57Bl/6 mice were immunized with either HIV gag p24 or dendritic cell (DC) targeted α-DEC-205 gag p24 in combination a microbial mimic, polyICLC. The vaccine was delivered via intranasal (i.n.), subcutaneous (s.c.), intramuscular (i.m.) or intraperitoneal (i.p.) routes in a prime-boost fashion. One week post boost, the small intestinal lamina propria (SILP) or colonic lamina propria (CLP) lymphocytes were isolated and cultured in the presence of either p17 (control) or p24 (immunizing) peptides to examine cellular recall responses. Subsequently, to determine the longevity of mucosal immune responses, mice were immunized as above, and recall responses were tested after six months. The data was acquired using flow cytometry and analyzed using Flowjo (Treestar) and Prism (Graphpad Software) respectively.

Results: We illustrate the capacity of an i.n. administered vaccine to induce robust and long-lived responses within the SILP and CLP, characterized by α-HIV specific CD4+IFN-γ+ cells. i.n. (1.5%) CD4+IFN-γ+ cells and i.p. (1.4%) routes of immunization were superior to systemic routes of vaccination such as s.c. (0.1%) or i.m. (0.1% P < .0001). We utilized a DC targeting technique to enhance the uptake of the antigen complex by DCs. The utilization of α-DEC-205 gag p24 antibody significantly increased the potency of the α-HIV p24 response, exhibiting a two-fold increase in CD4+IFN-γ+ T cells (1.6% versus 0.8%), which was DC mediated. Characterization of the α-HIV specific CD4+ generated after i.n. vaccination revealed a predominant Th1 response, with enhanced levels of IFN-γ, IL-17, IL-1β producing T cells in the. In addition to CD4+ T cell responses, CD8+ responses were generated using a NYVAC-gag boost following α-DEC-205 priming. Furthermore, we observed that DC targeted vaccination induced immunity as long as six months following immunization at the site of the SILP (1.93%) and the Colonic LP (3.3%) and was significantly more potent than unconjugated gag p24.

Conclusions: Robust and long-lived α-HIV immune responses can be generated in the GI lamina propria using a novel, DC targeted vaccine.

357 Conserved Element DNA Vaccine based On HIV-1 or SIV sequences Increases T-Cell Breadth
Barbara K. Felber
NCI, Frederick, MD, United States

Background: HIV sequence diversity and potential “decoy” epitopes are hurdles in the development of an effective AIDS vaccine. We tested the hypothesis that a vaccine candidate composed of highly Conserved Elements (CE) of the HIV proteome excluding the variable regions would help overcome these problems. CE were selected based on both stringent conservation and association of specific elements with immune control. A prototype HIV DNA vaccine, expressing 7 CE identified in p24 gag as a single protein, was able to induce robust cross-clade specific immune responses in mice.

Methodology: Macaques were immunized by IM injection followed by electroporation with two DNA plasmids providing potential epitopes found in >99% of all HIV-1 M group sequences. Cellular immune responses were compared to those obtained upon vaccination with gag DNA only. As a second test of this concept, we also developed SIVp27gag CE vaccine and tested immunogenicity in DNA vaccinated macaques.

Results: HIV CEgag DNA vaccination induced robust immunity in all 10 vaccinated macaques, whereas full-length gag DNA vaccination elicited CE responses in only 5 of 11 animals targeting fewer CE per animal. CE DNA vaccination elicited highly cytotoxic T cells against CE, capable of Granzyme B production and degranulation, desired features for an effective vaccine. Importantly, boosting CE-primed macaques with DNA expressing full-length p55gag increased both magnitude of CE responses and breadth of Gag immunity, demonstrating altered immunodominance hierarchy in the presence of pre-existing CE-specific responses. Similarly, we found the vaccination with SIV p27gag CE induced antigen-specific responses. In contrast, vaccination with SIV p57gag induced poor CE-specific responses found only in 50% of the vaccinees. As for HIV CE, the SIV CE-specific responses were boosted by vaccination with DNA expressing complete Gag.

Conclusions: Combination of conserved elements and full-length immunogen provides a novel strategy to increase the magnitude and breadth of immune responses to Gag, and allows for the development and expansion of dominant responses. This vaccine allows the immune system to target the ‘Achilles heel’ of the virus, for which few escape pathways exist. Inclusion of a conserved element immunogen provides an effective strategy to broaden responses against any highly diverse pathogen by avoiding decoy epitopes, while focusing responses to critical and invariant viral elements.
358 DNA and Protein Co-Immunization Improves the Magnitude and Longevity of Humoral Immune Responses

George N. Pavlakis
National Cancer Institute, Frederick, MD, United States

Background: Understanding the quality of immune responses induced by different vaccine regimens is essential for improving the prospects of AIDS vaccines.

Methodology: To identify optimal regimens, we compared vaccination protocols that used DNA, protein, or a combination of DNA and protein using a classical prime/boost strategy or delivered in a co-immunization regimen combining the two vaccine components. Magnitude, breadth, longevity and mucosal dissemination of anti-Env humoral responses were monitored in vaccinated macaques. Rhesus macaques were vaccinated using electroporation with either DNA, DNA/protein co-immunization, or DNA prime followed by protein boost or by protein alone. As protein source, we used AT-2 inactivated SIV particles or HEK293 produced HIV or SIV Env. Humoral (including neutralizing, linear epitope and V1V2 antibodies) and cellular responses were followed over time. Some of the vaccinated macaques were challenged to determine immune correlates of protection.

Results: Protein only vaccination induced robust humoral responses, which rapidly declined. In contrast, co-immunization with DNA (IM delivered by needle) and protein induced long-lasting responses. We expanded on these observations and implemented several vaccine improvements, i.e. better env DNA plasmids, inclusion of IL-12 DNA as adjuvant and improved in vivo DNA vaccine delivery by intramuscular injection followed by in vivo electroporation (IM/EP) and inclusion of protein as boost or co-immunization regimen. Although DNA only vaccination achieved strong humoral responses, protein boost after DNA vaccination greatly increased Ab levels. Importantly, a co-immunization strategy of DNA/protein injected in the same muscle the same time induced highest and broad humoral responses. Similar data were obtained using either purified Env proteins or inactivated viral particles. Inclusion of DNA in the vaccine promoted persistence of plasma antibody levels for greater than 2 years. SIV DNA/protein vaccination induced: higher SIV Env-specific IgG in saliva; more responders with higher SIV Env-specific IgG in rectal fluids; higher and longer-lasting plasma bAb and Nab to homologous and heterologous Env; and Ab to V1/V2. Systemic and mucosal vaccine-induced Ab responses against SIVsmE660 correlated with slower virus acquisition upon challenge. In addition, vaccinated macaques showed strong protection against chronic viremia compared to controls. Similar to SIV, HIV DNA/protein (purified Env) vaccination also induced higher Ab levels compared to DNA only, including significantly higher levels of V1/V2 Abs.

Conclusions: DNA/protein co-delivery increases the magnitude and longevity of systemic and mucosal humoral immune responses in immunized rhesus macaques.

359 The Adjuvant Used in an ALVAC/gp120 Regimen Alters Plasmablast Homing Markers in Macaque and Humans

Luca Schifanella1, Shari Gordon1, Monica Vaccari1, Georgia Tomaras2, Mangala Rao3, David Venzon1, Susan Barnett4, James Tartaglia5, Silvia Ratto-Kim6, Genoveffa Franchini7
1National Cancer Institute, National Institutes of Health, Bethesda, MD, United States, 2Duke University, Durham, NC, United States, 3Walter Reed Army Institute of Research, Rockville, MD, United States, 4Novartis Vaccines and Diagnostics, Cambridge, MA, United States, 5Sanofi Pasteur, Swiftwater, PA, United States, 6United States Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States

Background: An ALVAC-HIV/gp120 vaccine provided limited but significant protection against HIV-1 acquisition (31.2%) in RV144 trial. Antibodies against the envelope were associated with reduced risk of HIV acquisition. The frequency of plasmablasts (PBs) has been shown to correlate with protection from SIV acquisition in macaques. Increasing evidence indicates that chemokines and their receptors have a central role in regional targeting PBs to hematopoietic, mucosal or inflammatory sites. The homing of vaccine-induced PBs could affect vaccine efficacy.

Methodology: 2 groups of 27 macaques each were immunized 4 times with ALVAC-SIV and received 2 boosts of gp120 formulated in ALUM or MF59. 1 month post immunization all animals and 47 controls were challenged with repeated low doses of SIVmac251 by intra-rectal route. We studied the vaccine efficacy and the frequency of PBs expressing alpha4beta7, CXCR4 and CXCR3. The frequency of the same markers in PBs was measured in 2 clinical cohorts (n=17 each) that were immunized with ALVAC HIV and boosted with 2 gp120 formulated in ALUM or MF59 together with ALVAC-HIV (RV132 and RV135)

Results: In macaques both strategies induced high titer of binding antibodies to SIV-gp120 and a similar frequency of specific PBs; however only ALUM group significantly reduced rate of SIV acquisition when compared to 47 unvaccinated controls (Log rank p=0.021). We found that, in naïve animals, the frequency of total PBs was correlated with the subset of PBs expressing alpha4beta7 (a mucosal homing marker) (CC=0.55, p=0.0001). 7 days after last vaccination the MF59 group showed an increased frequency of circulating PBs expressing CXCR3 (an inflammatory site homing marker) and a significant decrease in the frequency of the alpha4beta7 PBs (p=0.0001, p=0.0001). The frequency of vaccine-induced alpha4beta7 PBs was higher in ALUM group while the frequency of CXCR3 PBs was higher in the MF59 group (p=0.01, p=0.03). Only in the ALUM group the frequency of PBs expressing alpha4beta7 was correlated with the amount of rectal IgA and IgG against the V2 region of mac251 (p=0.04 and p=0.02)

In the clinical cohorts we observed a significant higher frequency of circulating alpha4beta7 PBs in the ALUM group when compared with the MF59 group (p=0.03); however, no differences in CXCR3 expression was observed between the 2 groups.

Conclusions: Our data indicate that different adjuvants alter the expression of chemokine and integrin receptors on PBs that, in turn, affect their homing potential to tissues. We found no correlation between the expression of homing markers on PBs and reduced rate of SIV acquisition. Boosting with gp120 with ALUM adjuvant induces a significantly higher frequency of alpha4beta7 PBs than boosting with gp120 with MF59 when measured in the two clinical cohorts.
360 ALVAC-SIV/gp120 Efficacy Is Not Improved by the Increase of Anti-Envelope B and T-Cell Responses
Monica Vaccari1, Shari N. Gordon2, Brandon F. Keele3, Georgia D. Tomaras3, Mangala Rao3, Mario Roederer4, Donald M. Stablein5, Sanjay Phogat6, Susan W. Barnett2, Genoveffa Franchini1
1NIH, NCI, Bethesda, MD, United States, 2Duke Human Vaccine Institute, Durham, NC, United States, 3USMHRP, Walter Reed Army Institute of Research, Silver Spring, MD, United States, 4NIH, NIAID, Bethesda, MD, United States, 5The EMMES Corporation, Rockville, MD, United States, 6Sanofi Pasteur, Swiftwater, PA, United States

Background: A prime-boost regimen of recombinant canarypox priming (ALVAC-HIV) with HIV (Clade B and E) -gp120 protein boosting formulated in Alum resulted in significant but limited protection from HIV acquisition in the Thai Trial (RV144).

We hypothesized that the use of the Th1/Th2- adjuvant MF59 as an alternative to the Th2- Alum, could improve the protection elicited by the ALVAC-SIV/gp120 vaccine platform, by increasing envelope specific antibody and T cell responses.

Methodology: We vaccinated 54 macaques four times (0, 4, 12 and 24 weeks) with the identical ALVAC backbone used in RV144, expressing SIV mac251 Gag-pro and gp120TM (instead of the HIV-1 Envs used in RV144), and then boosted 27 macaques twice (12 and 24 weeks) with both SIVmac251- and SIVsmE660- gp120 proteins formulated either with Alum or with MF59. A total of 24 adjuvanted or naïve animals were included as concurrent controls and additional 23 as historical controls. All the animals were exposed to 120 TCID50 of SIVmac251, by the intra-rectal route, once a week, at 4 weeks after the last immunization.

Results: ALVAC-SIV/gp120 adjuvanted in MF59 significantly increased env-specific binding antibodies, ADCC, neutralizing antibodies, and CD4+ T-cell responses compared to the identical regimen adjuvanted in Alum. However the Alum-group induced significantly higher titers of envelope specific IgG3 antibodies in the plasma and cyclic V2 responses in mucosal compartments compared to the MF59-group. In addition, the Alum-group (RV144-like) resulted in significant protection from SIVmac251 acquisition (log rank p=0.021) while the MF59-group did not improve the efficacy of the ALVAC/gp120 regimen (log rank p=0.56).

Conclusions: The combination of ALVAC-SIV-gp120/MF59 was overall more immunogenic than that of ALVAC-SIV-gp120/Alum; however it did not increase protection against SIVmac251 acquisition and altered both the IgG subclass and mucosal V2 responses.

361 Altering the Prime Affects ALVAC-SIV/gp120 Immunogenicity and Efficacy
Shari N. Gordon1, Monica Vaccari1, Georgia D. Tomaras3, Mario Roederer4, David Vonzoni5, Dan H. Barouch6, Barbara Felber6, Nelson L. Michael7, James Targa8, Genoveffa Franchini1
1Animal Models and Retroviral Vaccine Section, NCI, National Institutes of Health, Bethesda, MD, United States; 2Duke Human Vaccine Institute, Durham, NC, United States; 3Vaccine Research Center, NIAID, National Institutes of Health, Bethesda, MD, United States; 4Biostatistics and Data Management Section, NCI, National Institutes of Health, Bethesda, MD, United States; 5Center for Virology and Vaccine Research, Beth Israel Deaconess Medical Center, Boston, MA, United States; 6Human Retrovirus Pathogenesis Section, Vaccine Branch, NCI, National Institutes of Health, Bethesda, MD, United States; 7Walter Reed Army Institutes of Research, US Military HIV Research Program, Silver Spring, MD, United States; 8Sanofi Pasteur, Swiftwater, PA, United States

Background: The 31.2% efficacy afforded by ALVAC-HIV/gp120 in the RV144 Thai Trial needs to be improved. ALVAC-SIV/gp120 vaccines tested in a SIVmac251 macaque model also demonstrated partial efficacy ~40% at each challenge. DNA vaccines and alternate adenoviral vectors such as Adenovirus 26 are clinically relevant vaccine candidates that could be used in combination with ALVAC/gp120. Thus we used the macaque model to test if priming the immune system with DNA or Ad26 as opposed to ALVAC would improve the immunogenicity and efficacy of ALVAC-SIV/gp120 vaccines.

Methodology: Twenty-seven macaques were given four vaccinations with ALVAC expressing SIV genes. A second cohort of twenty-four macaques had the two initial ALVAC vaccinations replaced with either two intramuscular DNA injections or a single intramuscular injection with Adenovirus 26, all expressing SIV genes. All vaccinated animals were boosted with ALVAC-SIV and gp120 protein in alum. Four weeks post immunization, vaccinated macaques and 41 controls were given repeated low-dose intra rectal challenges with SIVmac251. The immunogenicity and efficacy of each regimen was evaluated.

Results: DNA-ALVAC-SIV/gp120, Ad26-ALVAC-SIV/gp120 and ALVAC-SIV/gp120 vaccines all induce high titer gp120 binding antibodies that recognize the V1/V2 region. The Ad26 primed group demonstrated significantly greater neutralization of SIV tier 1-like viruses, ADCC and increased SIV specific T cell responses. To evaluate efficacy, we compared the rate of SIV acquisition of each vaccination regimen to controls and found that both ALVAC-SIV/gp120 and DNA-ALVAC-SIV/gp120 vaccines significantly delayed SIV infection with an estimated efficacy of 40.2 and 51.2% respectively. However the rate of SIV acquisition was not significantly different between the Ad26-ALVAC/SIV+gp120 regimen and controls.

Conclusions: Priming with DNA or ALVAC followed by ALVAC/gp120 boosting resulted in a significant reduction in the rate of SIV acquisition. However, we observed a lack of protective efficacy when Ad26 was combined with ALVAC-SIV/gp120. This finding differs from other studies that demonstrated protective efficacy with an Ad26-MVA regimen using an alternate SIVmac251 challenge stock 3-9 months post vaccination. Understanding the evolution of protective responses and vaccine combinations that enhance efficacy can inform the design of human trials that use these vaccine modalities.

362 Immunization of Humanized BLT Mice Against HIV Influences Early Immune Responses and Viral Loads
Timothy E. Dudek1, Colby R. Maldini2, Vladimir D. Vrbanac2, Elizabeth F. Mellors1, Damien Tully1, Marcus Altfeld1, David M. Knipe3, Andrew M. Tager2, Todd M. Allen1
1Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States; 2Massachusetts General Hospital, Boston, MA, United States; 3Harvard Medical School, Boston, MA, United States

Background: The precise specificity of humoral and cellular immune responses has been shown to affect the control of SIV/HIV replication. While the SIV-infected rhesus macaque model has proven invaluable for elucidation of the mechanisms of HIV disease pathogenesis and vaccine efficacy, differences in host and viral genetics limit the model’s use for the study of human HIV-specific immune responses elicited by infection or immunization.
Recent studies have shown that the immune system in the humanized BLT mouse model is functional and HIV specific cellular immune responses elicited during infection of these mice appear to accurately reflect those of humans, indicating that this model may be useful for HIV vaccine studies.

**Methodology:** Four sets of mice reconstituted from distinct human donors were immunized with a PLGA-Gag microparticle prime and then boosted with a replication-defective HSV viral vector encoding HIV Gag (d106S-Gag). Mice were then challenged four weeks later with the HIV molecular clone JR-CSF, 2 groups with a moderate dose of 20,000 TCID50 intravaginally (Experiments #1 and #2) and 2 groups with a high dose of 50,000 TCID50 intraperitoneally (Experiments #3 and #4).

**Results:** Gag immunized mice exhibited a stronger and more rapid cellular immune response against Gag versus mock or GFP-immunized mice, indicative of an anamnestic response.

Gag immunization in Experiment #1 produced a delay in detectable plasma viremia by up to 6 weeks in 3/6 mice, with a mean difference in viral loads of 1.7 log10 (p ≤ 0.03) during this period, while in Experiment #2 1/9 mice exhibited a delay in plasma viremia by up to 4 weeks and the group had a 0.4 log10 mean difference at 6 and 10 weeks post-challenge (p ≤ 0.03). Following a high-dose intraperitoneal challenge (Experiments #3 and #4) we observed a more modest 0.5 log10 difference in the mean viral loads at weeks 2 and 6 post-challenge (p = NS and p < 0.04, respectively). Overall, the combined results show that Gag immunization was highly associated with lower viral loads (p = 0.003) over the 12 week challenge period.

**Conclusions:** The detection of anamnestic responses and the consistent reduction in viral loads across numerous groups illustrate that humanized BLT mice can be successfully utilized for HIV vaccine studies. This small animal model of HIV infection and immunology may therefore play an important role in the development of HIV vaccines, including efforts to redirect immunity towards more critical targets of the virus.

### 363 Antibody Responses in Anogenital Secretions of RV305, a Late Boost Vaccination of RV144 Volunteers

**Siriwat Akapirat**¹, Chitrarot Karnasuta¹, Viethth Ngauy¹, Robert J. O’Connell¹, Punnee Pitisuthithum², Supachai Reks-Ngam³, Nelson L. Michael⁴, Mark S. De Souza⁵, Jerome H. Kim⁶, Nicolas Karasavvas⁷

¹Retrovirology, Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, ²Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, ³Disease Control, Ministry of Public Health, Nonthaburi, Thailand, ⁴Retrovirology, Walter Reed Army Institute of Research, Silver Spring, MD, United States

**Background:** Anogenital mucosae are the primary sites of HIV-1 acquisition. RV144 is the only HIV vaccine trial to show efficacy to date. HIV uninfected RV144 volunteers (n=162) who completed all vaccinations 6-8 years earlier, were enrolled into the RV305 and were randomized to receive 2 injections of ALVAC-HIV or AIDSVAX B/E or a combination of both, or placebo, at day 0 and 6 months. We measured serial antibody responses in anogenital secretions.

**Methodology:** IgG and IgA responses in cervical vaginal mucus (CVM), seminal plasma (SP), and rectal secretion (RS) at study entry and 2 weeks post first and second injection were tested by ELISA against HIV-1 envelope gp120 CRF01_AE (A244gD), and gp70V1V2 scaffold proteins derived from CRF01_AE (92TH023) and subtype B (CaseA2).

**Results:** Prior to boosting, IgG A244gD responses in CVM were similar in all vaccination groups with geometric mean titers (GMT) range of 61-66. GMT increased to 1745 and to 904 two weeks after the first boost, but decreased to 994 (p = 0.01) and 556 (p=0.10) following the second boost in AIDSVAX B/E and ALVAC-HIV/AIDSVAX B/E groups, respectively. Gp70V1V2 IgG responses in CVM were undetected in all groups prior to boosting. After the first injection, responses were higher in AIDSVAX B/E followed by ALVAC-HIV/AIDSVAX B/E; gp70V1V2 B, GMT=35 and 28, respectively; gp70V1V2 AE, GMT=228 and 133, respectively. After the second boost, responses to gp70V1V2 AE decreased to GMT=65 (p<0.01) and 50 (p=0.04), respectively, but responses to gp70V1V2 B remained unchanged. In SP, IgG responses to A244gD and gp70V1V2 AE were detected after the first boost in the AIDSVAX B/E and ALVAC-HIV/AIDSVAX B/E groups with A244gD GMT=125 and 126, respectively, and for gp70V1V2 AE GMT=28 in both groups. IgG GMT to A244gD decreased to 62 (p<0.01) and 70 (p<0.01), respectively, while gp70V1V2 AE reactivity was undetectable after the second boost. SP IgG responses to gp70V1V2 B were not detected in either group. In the ALVAC-HIV group, CVM and SP IgG responses were undetectable for all proteins tested. IgG responses were not detected in RS from any vaccination group and no IgA responses were detected in any of the samples tested (1:100 sample dilution).

**Conclusions:** Antibodies induced in RV305 anogenital secretions indicate that IgG responses to HIV-1 gp120 and to gp70V1V2 scaffold proteins in CVM and SP were inducible after being boosted with AIDSVAX B/E or ALVAC-HIV/AIDSVAX B/E. We did not detect IgG antibody responses in mucosal secretions from the group receiving ALVAC-HIV only and in RS from all groups. IgA responses were absent in mucosal secretions from all groups. The induction of HIV-1 antigen specific IgGs in CVM and SP suggests a possible mechanism by which the RV144 regimen provided protection from HIV-1 acquisition in heterosexual couples.

### 364 Divergent HIV-Specific CD4 T-Cell Response Profiles in HIV Vaccine Trials

**Franco Pissani**¹, Sebastien Maloveste¹, Bruce Shultz¹, Sorachai Nitayaphan², Prasert Thongcharoen², Punnee Pitisuthithum³, Michael Eller³, Silvia Ratto-Kim³, Mary Marovich¹, Hendrik Streeck¹

¹Cellular Immunology, Military HIV Research Program, Silver Spring, MD, United States, ²Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, ³Division of Microbiology, Siriraj Hospital, Mahidol University, Bangkok Noi, Thailand, ⁴Clinical Tropical Medicine, Mahidol University, Nakhon Pathom, Thailand, ⁵Military HIV Research Program, Silver Spring, MD, United States

**Background:** A fundamental goal for an HIV vaccine is to induce long-lived protective immunity. However, in HIV vaccine trials conducted to date, humoral responses are modest and appear to wane rapidly after vaccination. Given the critical role of CD4 T cell help in the induction of affinity-matured, long-lived antibody responses, we extensively characterized CD4 responses developed using a wide range of previously studied vaccine candidates and adjuvants.
Methodology: Cryopreserved peripheral blood mononuclear cells were obtained from samples corresponding to peak immunogenicity times of several HIV vaccines including ALVAC alone delivered via different routes, ALVAC prime/ AIDSVAX boosts, ALVAC prime/ Env protein boost, DNA prime/ Ad5 boost, subtype B gp120 alone, and MVA alone. Chronically infected HIV specimens were used as reference. HIV-specific CD4 T cell responses were assessed by intracellular cytokine staining using multicolor flow cytometry.

Results: HIV-specific CD4 T cell responses were detectable in all vaccines and patients, however, the magnitude, cytokine profile and protein dominance varied substantially. Overall, PBMC from vaccine recipients primarily targeted Env, compared to chronic HIV specimens that primarily targeted Gag. ALVAC immunizations delivered intradermally or loaded on autologous dendritic cells generated CD4 T cell responses to Env-derived peptides while intramuscular delivery elicited responses targeting Gag peptides. Env protein boosting of intramuscular ALVAC primes overwhelmingly shifted the response to Env. In this regard, boosting with oligomeric gp160 had a stronger effect than bivalent gp120. CD4 T cells responding to ALVAC vaccination alone predominantly produced TNFα and IL-21 in response to Env, whereas Gag invoked more IFNγ than IL-21. Oligomeric gp160-boosted PBMCs produced TNFα and IFNγ in response to both Env and Gag, while the response in bivalent gp120-boosted PBMC consisted of TNFα, IFNγ, and IL-21, albeit as mostly single-cytokine producing cells. MVA immunizations, either intradermal or intramuscular, overwhelmingly generated more to Env peptides than Gag specific responses. Using principal component analysis (PCA), the induced response patterns showed a very distinct cytokine profile that only partially overlapped with the CD4 T cell responses seen in natural HIV infection.

Conclusions: Immunization vectors and antigens differentially influence the CD4+ T cell response. Vaccine-specific immune responses vary drastically from those developed through natural HIV-1 infection. Ongoing analyses of specific CD4 T cell responses induced by various vaccination vectors and delivery routes may elucidate optimal means of invoking strong antibody responses in HIV vaccine recipients.

Immunogenicity and Reactogenicity of Cervarix® Versus Gardasil® in HIV-Infected Adults: An RCT
Lars Toft1, Merete Storgaard2, Martin Müller2, Peter Sehn3, Jesper Bondel3, Martin Tostrup1, Lars Østergaard1, Ole S. Søgaard2, Lars Østergaard1
1Department of Infectious Diseases, Aarhus University Hospital, Aarhus, Denmark, 2Research Program Infection and Cancer, German Cancer Research Center, Heidelberg, Germany, 3Chemical Biology Core Facility, European Molecular Biology Laboratory, Heidelberg, Germany, 4Department of Pathology, Copenhagen University Hospital, Hvidore, Denmark

Background: Most human papillomavirus (HPV)-related cancers are potentially vaccine-preventable. Persons infected with HIV have excess risk of developing HPV-related cancers but are often hypo responsive to immunization. We hypothesized that in HIV-infected adults the TLR4 agonist-adjuvanted bivalent HPV vaccine would be more immunogenic than the alum-adjuvanted quadrivalent HPV vaccine.

Methodology: We performed an investigator-initiated, double-blind, controlled trial randomizing HIV-positive adults to receive either three doses of the bivalent HPV vaccine (Cervarix, GlaxoSmithKline) or the quadrivalent HPV vaccine (Gardasil, Sanofi Pasteur MSD) at 0, 1.5 and 6 months. Immunogenicity and safety were evaluated for up to 12 months. Primary endpoints were serum neutralizing anti-HPV-16 and anti-HPV-18 antibody geometric mean titers (GMTs) at 7 months measured by pseudovirion-based neutralization assay (PBNA). The HPV-DNA status of the participants was determined before and after immunization.

Results: Ninety-two participants were included in the study. Anti-HPV-18 GMTs were higher in the bivalent HPV vaccine group compared with the quadrivalent HPV vaccine group at 7 and 12 months, and no significant differences were found in anti-HPV-16 GMTs among vaccine groups. In the bivalent HPV vaccine group, female compared with male participants had higher anti-HPV-16/-18 GMTs. No gender-specific differences in GMTs were found in the quadrivalent HPV vaccine group. Mild injection site reactions were more common in the bivalent HPV vaccine group than in the quadrivalent HPV vaccine group (91.1% vs. 69.6%; P = .02). No serious adverse events occurred.

Conclusions: Compared with the quadrivalent HPV vaccine, the bivalent TLR4-adjuvanted HPV vaccine induced superior vaccine responses among HIV-infected women whereas in HIV-infected men the difference in immunogenicity was less pronounced. Both vaccines were well tolerated. Comparative efficacy trials of HPV immunization in HIV-infected individuals are warranted.

The Specificity of V3 Antibodies in RV144 Plasma Implicated in Reducing HIV Infection
Susana Zolla-Pazner1, Constance Williams2, Morgane Rolland3, Paul Edlefsen4, Xiang-Peng Kong5, Arthur Nadus6, S. Tovanabutra7, Supachai Rerkas-Ngarm8, Merlin Robbi9, Nelson Michael9, Jerome Kim6
1Pathology, VA and New York University Medical Centers, New York, NY, United States, 2Pathology, New York University Medical Center, New York, NY, United States, 3Military HIV Research Program, Bethesda, MD, United States, 4Fred Hutchinson Cancer Research Institute, Seattle, WA, United States, 5New York University Medical Center, New York, NY, United States, 6Military HIV Research Program and HM Jackson Foundation, Bethesda, MD, United States, 7Ministry of Public Health, Bangkok, Thailand

Background: The RV144 clinical trial was shown to have an estimated vaccine efficacy of 31%. IgG antibodies (Abs) to V2 significantly inversely correlated with infection risk. Recently it was shown that Abs to V3 also inversely correlated with infection risk when vaccinees had low levels of Env-specific plasma IgA, and ADCC and neutralizing Abs. In addition, sieve analysis of breakthrough viruses identified significant differences in vaccine- and placebo-recipients in the proportion of certain residues present at positions 307 and 317 in V3. Studies were therefore performed to determine the fine specificity of V3 Abs in RV144 plasma and their possible role in reducing HIV infection.

Methodology: Plasma specimens drawn two weeks after the last immunization from 40 vaccinees and 20 placebo recipients were tested in ELISA at a 1:100 dilution for reactivity vs. bivalent cyclic V3 peptides (cV3s).

Results: Of 8 cyclic V3 peptides studied, reactivity was strongest vs. clade B cV3s. The next strongest responses were with clade A, AG and C cV3s. The weakest responses were seen vs. clade AE cV3s (92THO23 & A244). The relative strengths of responses were consistent with analyses of the distance between the V3 sequences used in the assays. Plasma from placebo recipients were non-reactive. Seven variants of BA and A244 cV3s with substitutions for I307 and F317 were also tested. Vaccinees’ plasma were most reactive with cV3 peptides containing I307 (which was present in the vaccine), and much less...
HIV Cell Tropism Dependent Impact of CTL Escape Mutations in Gag On Viral Replicative Capacity

Benedikt Grandel1, Cara Wenne1, Franziska Winter1, Sven Breitwieser1, Bernd Salzberger1, Arne Schneidewind2

1Internal Medicine I, University of Regensburg, Regensburg, Germany; 2Internal Medicine I, University of Bonn, Bonn, Germany

Background: KK10 (K263-K272) within the N-terminus of HIV p24/Gag represents the immunodominantly targeted CTL epitope in HLA-B27+ HIV-infected individuals. Due to its association with delayed disease progression B27 is considered to be protective during HIV infection. The stereotypical escape mutation R264K alters the KK10 epitope in a way that it is no longer presented by B27, in vitro causing a substantial reduction in viral replicative capacity in targeted lymphocytes at the same time. This replication defect can be attributed to an altered interaction between p24 and the cellular protein Cyclophilin A. Efficient replication of the R264K escape variant can be restored in vivo and in vitro by the selection for the secondary compensatory mutation S173A.

Results: In vitro analyses of the phenotype of R264K have been performed with X4 tropic viral strains using primary lymphocytes or cell lines as target cells. Since the R5/X4 tropism shift usually occurs rather late in the course of HIV infection and R5+ cells are a major reservoir for HIV it would be important to confirm these findings with R5 tropic target cells.

Methodology: Chimeric HIV-1 proviruses were engineered fusing a backbone of the X4 tropic NL4-3 strain (containing the respective mutations of interest in Gag) with an Env coding part of the R5 tropic YU2-strain. Chimeric NL4-3/YU2 viruses were used to infect PMA-stimulated THP1 cells (macrophage-like cells). Relative replication capacities of the viral variants were compared to that of NL4-3/YU2 chimeric virus without additional Gag mutations (wild-type). Viral replication was monitored over a period of several days by measuring p24 content in supernatant by ELISA. Similar experiments were performed with various NL4-3 variants in CD4+ T-cell lines.

Results: In CD4+ T-cells the R264K variant replicates with about 10% efficiency compared to wild-type NL4-3. In contrast, Gag mutation R264K in context of a R5 tropic chimeric NL4-3/YU2 virus mediates no reduction in viral replicative capacity when infecting macrophage-like cells.

Conclusions: This striking difference in viral replication capacities of specific viral variants with HLA-B27 associated Gag mutations in context of differential viral cell tropism raises questions about the nature of the observed protective phenotype of HIV-B27. Mutational escape from the immunodominant CTL pressure against the KK10 epitope in HLA-B27+ individuals seems to be restricted in lymphocytes while macrophages could be permissive for replication of the respective variants. Our observations strongly suggest that also specific Gag mutations can influence cellular tropism of HIV.

Epitope Targeting and the Antibody-Dependent Cellular Cytotoxicity Response Against HIV-1

Priyamvada Acharya1, William D. Tolbert2, 3, Lei Yu2, 4, James E. Robinson5, Loic Martin6, Peter D. Kowg1, Yongjun Guan2, 4, Anthony L. DeVico2, 7, George K. Lewis2, 4, 1Vaccine Research Center, National Institutes of Health, Bethesda, MD, United States; 2Institute of Human Virology, Baltimore, MD, United States; 3Department of Biochemistry and Molecular Biology, University of Maryland School of Medicine, Baltimore, MD, United States; 4Department of Microbiology and Immunology, University of Maryland School of Medicine, Baltimore, MD, United States; 5Department of Pediatrics, Tulane University Medical Center, New Orleans, LA, United States; 6Service d’Ingénierie Moléculaire des Protéines, CEA, Gif-sur-Yvette, France; 7Department of Medicine, University of Maryland School of Medicine, Baltimore, MD, United States

Background: Antibody-dependent cellular cytotoxicity (ADCC) has been linked with protection against HIV-1. In the RV144 trial that showed an estimated efficacy of 31%, high levels of ADCC inversely correlate with infection risk. Non-neutralizing epitopes in the C1 region of gp120 have been implicated as potential targets for protective antibody responses elicited by vaccination, although antibody-binding titers against these epitopes do not correlate with protection. We hypothesized that differences in the mode of epitope recognition may be responsible for large differences in ADCC activities between antibodies targeting the C1 region of gp120.

Methodology: For atomic level definition of binding epitopes, we determined the structures of two monoclonal antibodies (mAbs), N5-i5 and 2.2c, that target the C1 region of gp120, in complex with gp120 core in the CD4-triggered conformation. ADCC measurements were carried out using CEM-NKr-CCR5 target cells sensitized with recombinant gp120 from the HIV-1Ba-L isolate. Fluorescently labeled N5-i5 was used in a competition strategy to measure N5-i5 and 2.2c binding to CEM-NKr-CCR5 target cells sensitized with gp120.

Results: Monoclonal antibodies (mAb) N5-i5 and 2.2c differed 75-fold in their ADCC potency. N5-i5 and 2.2c recognized overlapping but distinct epitopes in the C1-C2 region of gp120. While N5-i5 contacted topological layers 1 and 2 of gp120, 2.2c contacts were restricted predominantly to layer 1 with few contacts with layer 2. We also found that the heavy and light chains of bound N5-i5 and 2.2c were switched. Hybrid variants of the antibodies with their VH
and VL domains swapped, showed no difference in cell surface binding. While the ADCC potency for N5-i5 did not show any significant difference between the wild-type and the VH/VL swapped version, swapping VH and VL domains improved ADCC potency of 2.2c by 7-fold.

**Conclusions:** The ability of antibody to cross-link antigen and positioning of its CH2 domain were found to contribute to ADCC potency, indicating that ADCC function depends on the orientation of antibody binding even when overlapping epitopes are involved. These data provide a framework for understanding the discordance between epitope-specific binding assays and ADCC as correlates of reduced infection risk in the RV144 trial. Further, they set the stage for an atomic level understanding of the role of precise epitope targeting in ADCC and similar Fc-mediated effector functions of antibodies.

### 369 Complex Impact of Reversion Mutations and CD8+ T Cell Escape Mutations On HIV-1 Fitness

**Hongshuo Song**, Tamny Bhattacharya, Nilu Goonetilleke, Kevin Wience, Andrew McMichael, George Shaw, Beatrice Hahn, Alan Perelson, Barton Haynes, Feng Gao

**Duke Human Vaccine Institute, Duke University Medical Center, Durham, NC, United States**  
**Duke Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom**  
**Weatherall Institute of Molecular Medicine, University of Pennsylvania, Philadelphia, PA, United States**

**Background:** Mutations that revert back to the ancestral state frequently occur in the HIV-1 genome during infection and have been considered to render the viruses more fit. However, their impact on viral fitness and interactions with the immune escape mutations have not been evaluated in their cognate transmitted/founder (T/F) viral genomes.

**Methodology:** Our previous study showed that viruses containing both cytotoxic T lymphocyte (CTL) escape mutations and reversion mutations are as fit as the T/F viruses. To precisely determine the role of reversion mutations, we generated the T/F mutants that contained either reversion mutation alone or together with CTL escape mutations and determined its impact on the viral fitness in primary CD4+ T cells using the PASS fitness assay.

**Results:** The reversion mutation V247I in the TW10 CTL epitope in Gag could partially restore the fitness loss caused by the CTL escape mutation T242N in the same epitope. However, the reversion mutation V247I or I64T in Tat/Rev alone had no impact on fitness of the T/F virus. The CTL escape mutations G248A in Gag and R355K in Env did not have any fitness cost. Interestingly, the CTL escape mutation G248A, like the reversion mutation V247I, could also partially compensate the fitness loss caused by the T242N mutation. Both the V247I and G248A mutations together fully restored the fitness loss of the T242N mutant. Positions 242, 247 and 248 are not located at p24 pentamer or hexamer interfaces and therefore should not affect the capsid assembly. In addition, homology modeling of p24 monomers demonstrated that mutations at these positions are not expected to significantly affect stability of the helix 6 structure.

**Conclusions:** Our results showed that reversion mutations might not render their cognate T/F virus more fit in vitro but could partially restore the fitness loss caused by the CTL escape mutation, and a CTL escape mutation could also partially compensate the fitness loss due to the other CTL escape mutation. These findings demonstrated that the overall viral fitness is influenced by the complex interplay of different mutations.

### 371 Linkage Between Disease Status and a Naturally Arising Mutation in Functional Region of HIV-1 Nef

**Stanley C. Meribel**, Zafrai Hasan, Hiroyuki Gatanaga, Toshiyuki Miura, Aki Kawana-Tachikawa, Shinichi Oka, Takamasa Ueno

**1Center for AIDS Research, Kumamoto University, Kumamoto, Japan**  
**2AIDS Clinical Center, National Center for Global Health and Medicine, Tokyo, Japan**  
**3Institute of Medical Science, University of Tokyo, Tokyo, Japan**  
**4Institute of Tropical Medicine, Nagasaki University, Nagasaki, Japan**

**Background:** HLA class-I (HLA-I) downregulation by HIV-1 Nef has been shown to protect infected cells from CTL killing, thereby contributing to viral persistence in vivo. It achieves this through a number of highly conserved sequence (functional) domains. However, the in vivo implication(s) of naturally arising polymorphism(s) in HIV-1 Nef’s published functional domains associated with HLA-I down-regulation, still remain(s) elusive.

**Methodology:** We enrolled a total of 658 treatment-naive, chronically HIV-1 infected subjects. Plasma samples were collected after obtaining informed consent, HLA-typed, viral RNA extracted and amplified by nested RT-PCR. The resultant nef amplicons were directly sequenced by Sanger’s method. Only clade-B sequences with intact ORF (n=406) were included in the further analysis.

**Results:** The molecular epidemiology of our data set revealed a less conserved Met20 of Nef (78%; which is one of the HLA-I downregulation functional domains) than the subtype-B Nef sequences published in Los Alamos Database (91%, n=1467; http://www.hiv.lanl.gov). There is a preponderance of ile20 (18%) in our dataset, than in the Los Alamos sequences (7%), p<0.0001. Ile20 was found to be associated with higher plasma median viral load (p=0.009). Other codons which were associated with Ile20 show no contributory effect on the viral load enhancement of Ile20. There is also enrichment of HLA-C*03:03 in subjects harboring Ile20 (p = 0.0161).

**Conclusions:** Taken together, we identified a naturally arising polymorphism, Ile20, within HIV-1 clade-B nef’s functional domain associated with HLA-I down-regulation, that has a propensity for higher viral load in vivo.

### 372 Characterizing Acute HIV-1B CTL Escape by Full-Genome “Deep” Sequencing

**Christian L. Boutwell, Damian Tully, Rebecca Babitsky, Karen Power, Aaron Seese, Michael Sirignano, Marcus Altfield, Todd M. Allen**

**Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States**

**Background:** The cytotoxic CD8+ T lymphocyte (CTL) immune response is implicated in the suppression of acute HIV-1B plasma viral load from peak to set-point. The magnitude of this post-peak decline, and by extension the load at which set-point is established, varies widely across infections, but the determinants of this variation are incompletely defined. The well-documented capacity of HIV-1 to escape from CTL responses implicates differential loss of acute CTL response efficacy resulting from rapid HIV CTL escape as a potential determinant of CTL-mediated control. Here, we investigate the relationship between the timing of acute HIV-1B escape from the earliest CTL responses and the acute viral load trajectory.
**Methodology:** We comprehensively characterized HIV-18 CTL escape in acute subjects (Fiebig I-III) by longitudinal, near full-genome, deep sequencing (200-fold average depth per site) across 4-6 time points per subject in the first 180 days post-infection (dpi). The acute CTL response was quantified by autologous IFN-γ ELISPOT assay during the first 90 dpi for all HIV epitopes defined for each subject’s HLA class I genotype (LANL A list).

**Results:** Acute CTL escape was observed in all subjects (range: 3-6 epitopes) and impacted 20-70% of the targeted epitopes and 27-93% of the total acute CTL response. Extremely rapid escape was detected at 28 dpi in two subjects at which time escape variants already comprised as much as 48% of the plasma virus population. The overlay of modeled CTL escape kinetics curves on acute viral load trajectories reveals an apparent temporal relationship between CTL escape and deflections in post-peak viral load declines.

**Conclusions:** These preliminary data suggest that the loss of efficacy of acute CTL responses resulting from rapid CTL escape by HIV may contribute disproportionately to the overall capacity of the acute CTL response to suppress virus replication and control viral load.

---

**373 HIV-1 gp120-Specific Antibody Dependent Cell-Mediated Cytotoxicity in HIV-1 Elite Controllers**

Mariana M. Mata1, Fareeha Mahmood1, Elizabeth T. Golub2, Ruth M. Greenblatt3, Kathryn Anastos4, Marek Nowicki5, Mary Young6, Helen Durkin6, Seema N. Desai1, Linda L. Baum1

1Immunology/Microbiology, Rush University Medical Center, Chicago, IL, United States, 2Epidemiology, The Johns Hopkins University, Baltimore, MD, United States, 3Clinical Pharmacy, Medicine, Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA, United States, 4Medicine, Epidemiology and Population Health, Montefiore Medical Center, Bronx, NY, United States, 5Medicine, University of Southern California, Los Angeles, CA, United States, 6Pathology, SUNY Downstate Medical Center, Brooklyn, NY, United States

**Background:** In theThai RV144 HIV vaccine trial, antibody dependent cell-mediated cytotoxicity (ADCC) is the only vaccine induced immunological parameter that correlates inversely with infection. This suggests that protective HIV specific ADCC can be stimulated by vaccination. We hypothesized that natural production of HIV-specific ADCC antibodies may also be protective and that these antibodies may be at least partially responsible for HIV viral control observed in women who naturally control the virus without antiretroviral drugs, Elite controllers (EC).

**Methodology:** We compared the ADCC response of antibodies in the serum and cervicovaginal lavage (CVL) from 35 EC, 34 HIV-infected HAART initiators, and 35 HIV-uninfected women in a standard 51Cr-release assay. All were participants in the Women’s Interagency HIV Study (WIHS), the largest ongoing prospective cohort study of HIV among US women. The 35 EC in our study had stable or increasing CD4 T cell numbers, were not on antiretroviral therapy and had undetectable HIV RNA for ≥1.5 years. HAART initiators were evaluated at three visits: visit 1, an asymptomatic visit with comparable CD4 T cell count to the EC group; visit 2, the last visit before HAART; and visit 3, a progressing visit during treatment. Statistical comparisons were conducted using the Mann-Whitney or Wilcoxon Paired Test. Significant differences were considered when p<0.05.

**Results:** EC had significantly higher serum (see Fig.1) and CVL ADCC activity than HAART initiators (p≤0.009 at 1:10 CVL dilution); this difference was most prominent at visit 1, the asymptomatic visit. Another measure of this activity, serum ADCC antibody titer, was significantly higher in EC than in HAART Initiators: visit 1, p≤0.003; visit 2, p≤0.04; visit 3, p≤0.006. While 97% of EC and 77% of HAART Initiators (Visit1) had a detectable serum ADCC titer, CVL titers were present in 40% of the EC and 27% of the HAART Initiators (Visit 1). CVL ADCC antibody titers were detected in 17% of the women immediately prior to HAART and increased to 32% during HAART treatment. The HIV-1 seronegative women had no detectable gp120-specific ADCC.

**Conclusions:** HIV EC have higher serum and CVL ADCC antibodies against HIV-gp120 than HAART initiators. ADCC may contribute to the ability of EC to control viral load. Evidence that the proportion of women with CVL ADCC activity increases after the initiation of treatment suggests that HAART may facilitate a rebound in ADCC antibodies.

---

**374 CD8 T Cell Responses Emerging During Acute HIV Infection Drive Long-Term Control**

Hendrik Streeck1, Jean-Pierre Routy2, Heiko Jessen3, Anthony Kelleher4, Frederick Hecht5, Rafick-Pierre Sekaly6, Eric Rosenberg7, Todd Allen8, Mary Carrington9, Marcus Allfied10

1US Military HIV Research Program, Silver Spring, MD, United States, 2Chronic Viral Illness Service, McGill University Health Centre, Montreal, QC, Canada, 3Practice Jessen + Jessen, Berlin, Germany, 4Centre for Immunology, St. Vincent’s Hospital, Darlinghurst, Australia, 5School of Medicine, University of California San Francisco, San Francisco, CA, United States, 6VGTI, Port St Lucie, FL, United States, 7Massachusetts General Hospital, Boston, MA, United States, 8Ragon Institute, Cambridge, MA, United States, 9National Cancer Institute, Frederick, MD, United States, 10Heinrich-Pette Institut, Hamburg, Germany

**Background:** The emergence of HIV-specific CD8 T cell responses during acute HIV infection has been previously associated with a post peak decline of HIV viremia, resolution of clinical symptoms and the development of a semi-stable viral setpoint; this early viral setpoint has been shown to be highly predictive of disease outcome. Given the importance of early HIV-specific CD8 T cell responses, we assessed which particular HIV-specific CD8 T cell responses contribute to long-term control.

**Methodology:** 622 predominantly male (97%) Caucasian (83%) individuals with primary HIV-1 infection (Fiebig: n= 152 (2/3), 61 (4), 277 (5), 87 (6), 23 (nd)) were screened by IFNy Elispot for HLA class I-restricted, epitope-specific CD8+ T cell responses using optimally defined epitopes approximately 2 months post initial presentation. Longitudinal viral load, CD4 count and time to HAART were collected of all patients over an average period of 1000 days post presentation.

**Results:** Initial viremia and early viral set points were significantly associated with HLA class I expression (p<0.0001). Similarly, the time patients remained off antiretroviral therapy also showed significant association with HLA class I. In particular, patients with HLA-B57 and -B13 initiated HAART significantly
Neutralization of HIV-1 by antibodies that target the membrane-proximal external region (MPER) of the gp41 subunit of the HIV-1 envelope glycoprotein has been shown to correlate with their capacity to recognize MPER in a membrane context. We sought to assess if modification of the broad and potent MPER-specific HIV-1 neutralizing antibody 10E8 could enhance its recognition of MPER in a membrane context and potentiate its neutralization of HIV-1.

Methodology: Antibody residue positions in the vicinity or co-planar with the gp41 contact interface, though not within it, were chosen for modification. Antibody variants were tested for HIV-1 neutralization and for MPER recognition in soluble and lipid contexts. Crystallization of the 10E8 variant with the greatest effect on virus neutralization was undertaken in complex with gp41 MPER to decipher its mechanism of action.

Results: Six residue positions within the 10E8 heavy chain were chosen for mutagenesis. Aromatic residues were introduced into these positions individually or in combination. Up to 9-fold improvements in neutralization potency over wild-type 10E8 were observed against individual strains of a 5-isolate panel, and up to 4-fold mean improvements observed against all strains combined. Improvements in neutralization did not directly correlate with antibody recognition of MPER in a lipid context. The crystal structure of the most potent 10E8 variant was determined in complex with a peptide of gp41 MPER, though no additional contacts between the antibody and gp41 were observed.

Conclusions: We have defined residue modifications within the 10E8 heavy chain that improve antibody-mediated HIV-1 neutralization. Binding studies suggest improvements in neutralization were not associated with enhanced antibody recognition of MPER in a lipid context. The crystal structure of the most potent 10E8 variant in complex with gp41 MPER did not reveal additional contacts with the gp41 peptide, suggesting other mechanisms within the virion context are likely at play in the improved neutralization potency observed.
377 Distinct Functional Properties of HIV-Specific Cytolytic CD4 T Cells Compared To Th1 or CD8 T Cells
Susan Johnson1, Richard Lu1, Alexander Oster1, Franco Pissani1, Mary A. Marovich1, Diane L. Bolton1, Hendrik Streeck1
1 US Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States, 2 Division of AIDS, NIH/NIAID, Bethesda, MD, United States

Background: Control of HIV replication mediated by CD8 T cells is well documented, though some evidence suggest that CD4 T cells with cytolytic properties (CD4 CTL) may also contribute to control of viral replication. Indeed, reports have shown that HIV controllers possess higher frequencies of CD4 CTL than progressors. However, very little is known about the immunobiology of CD4 CTL and how to generate them with an HIV vaccine. Moreover, it is unclear whether they are actively infected and depleted by HIV.

Methodology: To further define HIV-specific CD4 CTL, we assessed gene and surface expression patterns of relevant markers in PBMCs, from chronically HIV-infected patients, responding to HIV-Gag peptide pools. We compared HIV-specific CD4 CTL versus HIV-specific CD8 CTL and T-helper cells using Fluidigm Technology and multicolor flow cytometry. We further evaluated susceptibility to HIV infection and by assessing the infectability of sorted HIV-specific CD4 CTL using a panel of four R5 primary isolates.

Results: Using index-cell-sorting paired with Fluidigm Technology as well as flow cytometry, we demonstrated that HIV-specific CD4 CTL have a distinct expression profile, which clearly distinguishes them, not only phenotypically, but also functionally from HIV-specific CD8 T cells and Th1 CD4 cells without cytolytic activity. In particular, expression of surface markers CD57 and KLRG1 was significantly higher on HIV-specific CD4 CTL (p = 0.0036, p = 0.0263 respectively) than on Th1 CD4 cells. Moreover, we found that both t-box transcription factors T-bet and eomesoderm (Eomes) are involved in the cytolytic program of CD4 T cells, similar to cytotoxic CD8 T cell. In contrast to CD4 CTL, HIV-specific CD8 T cells expressed NKG2D with higher level of Eomes, KLRG1 and CD57. Even though HIV-specific Th1 CD4 cells expressed T-bet, Eomes expression was absent in those cells, suggesting a role of Eomes in the cytolytic program of CD4 CTL. Nevertheless, HIV-specific Th1 CD4 cells are characterized by high expression of CD161. Interestingly, the expression levels of CCR5 were the lowest on CD4 Th1 cells and the highest on CD4 CTL. In a viral replication assay, we found that CD4 CTL, defined as expression of CD57 or KLRG1 on CD4 T cells, have a lower infectability than CD57- or KLRG1- CD4 T cells suggesting a distinct HIV-specific CD4 T cell subset that resists HIV infection.

Conclusions: Our data demonstrate that HIV-specific CD4 CTL have a distinct functional and phenotypic profile compared to HIV-specific CD8 CTL and CD4 Th1 cells. Furthermore, CD4 CTL express higher levels of CCR5 and are less prone to HIV infection compared to general Th1 CD4 T cells suggesting a CD4 T cell population that is more likely to persist during HIV infection.

378 CD8+ T Cells From HLA-B*57 ELITE Suppressors Inhibit Replication of HIV-1 Escape Mutants
Christopher W. Pohlmeyer1, Robert W. Buckheit2,3, Robert F. Siliciano1,4, Joel N. Blankson1
1 School of Medicine, The Johns Hopkins Medical Institution, Baltimore, MD, United States, 2 National Cancer Institute, Frederick, MD, United States, 3 The Johns Hopkins Medical Institution, Baltimore, MD, United States, 4 Howard Hughes Medical Institute, Baltimore, MD, United States

Background: Elite Controllers or Suppressors (ES) are individuals who maintain undetectable plasma viral loads by standard clinical assays in the absence of antiretroviral therapy. Multiple lines of evidence suggest that the control of viral replication in these patients is due to a strong and specific cytotoxic T lymphocyte (CTL) response. Escape mutations are believed to impair the ability of CD8+ T cells to control HIV-1 replication. Interestingly, viruses isolated from the plasma of ES have been shown to contain several escape mutations; it is not clear how immunologic control is maintained despite this virologic escape.

Methodology: Using site-directed mutagenesis, we constructed six NL4-3 based viruses with canonical escape mutations in one to three HLA-B*5703 Gag p24 epitopes. To determine the ability of CD8+ T cells to suppress replication of HIV-1 containing escape mutations, unstimulated CD4+ T cells of seven HLA-B*5703+ ES were infected with either wild type or one of the constructed escape variant variant viruses and cocultured with autologous CD8+ T cells at three target to effector ratios. Effector CD8+ T cells were either used directly ex vivo or first stimulated with peptides corresponding to either wild type or escape variant HLA-B*5703 Gag epitopes to see if this would induce stronger suppression of replication. Intracellular cytokine staining was performed in order to determine the mechanisms involved in the suppression of these escape variants.

Results: In this study, we investigated the effect escape mutations within HLA-B*57+ restricted Gag epitopes have on the ability of ES CD8+ T cells to suppress replication of HIV-1 in autologous CD4+ T cells. Unstimulated CD8+ T cells suppressed replication of all six escape mutants at levels that were comparable to the level of suppression of wild type virus. Intracellular cytokine staining revealed low baseline CD8+ T cells responses to wild type and
escapes variant peptides; however, culture of PBMC with peptides corresponding to either wild type or escape variant HLA-B*57 Gag epitopes for seven days resulted in increased IFN-γ and perforin expression in response to overnight stimulation with either wild type or escape variant peptides.

Conclusions: Our data demonstrate that CD8+ T cells from ES are capable of suppressing replication of virus harboring escape mutations in HLA-B*57 restricted Gag epitopes. Additionally, our data suggest that ES CD8+ T cells are capable of generating effective de novo responses to escape mutants. These results may explain why ES are able to control viral replication despite virologic escape.

Mechanisms of HIV Latency

379LB The Tat Inhibitor, Cortistatin A, Suppresses Transcription and Reactivation of HIV Latent Cells
Guillaume Mousseau1, Remi Fromentin2, Nicolas Chomont2, Susana T. Valente1
1The Scripps Research Institute, Jupiter, FL, United States, 2Vaccine and Gene Therapy Institute, Port Saint Lucie, FL, United States

Background: Despite the immense success of HIV anti-retroviral therapy (ART) to reduce replication to very low levels, it fails to eradicate the virus. HIV persists in latently and productively infected CD4+ T cells in infected subjects undergoing ART. Current therapies are unable to inhibit reactivation of transcription from latently infected resting cells as well as production from active persistent cellular reservoirs. Thus, novel classes of compounds are needed to eliminate this low level viremia that also contributes to persistent and damaging chronic immune activation.

The HIV Tat protein, a potent activator of HIV gene expression, is essential for integrated viral genome expression. Tat binds the 5' terminal region of HIV mRNA's stem-bulge-loop structure, the Trans-activation Responsive (TAR) element to activate transcription. Given Tat's crucial requirement for virus replication, it has been the target for the development of small molecule compounds, however so far none has yet reached the clinic.

Methodology: We found that didehydro-Cortistatin A (dCA), an analogue of a natural steroidal alkaloid is the most potent Tat inhibitor described to date, it binds selectively to the basic domain of Tat, the region responsible for the interaction with TAR, at subnanomolar concentrations. dCA reduces Tat mediated transcriptional initiation/elongation from the viral promoter to inhibit HIV-1 replication in acutely and chronically infected cells. Here we show that dCA can reduce residual viremia in HIV latently infected cells and block viral reactivation.

Results: dCA reduces residual viral production from several cell models of HIV latency, establishing a state of "super latency", rendering very difficult viral reactivation into a productive infection using the usual panel of activators (HDAC inhibitors, PKC activators, cytokines, etc). A concomitant reduction of RNA polymerase II recruitment to "super latent" promoters is observed. Only a strong activator such as Tat can reactivate the virus temporarily. Furthermore, arrest of dCA treatment does not result in viral rebound, as the promoter is transcriptionally shut-off. As expected, latent cell lines either mutated in TAR or Tat are insensitive to dCA. Most importantly, dCA inhibits HIV reactivation upon homeostatic and antigenic stimulation of CD4+T cells isolated from virally suppressed patients undergoing ART.

Conclusions: In sum, dCA is an exciting anti-HIV molecule that could inhibit and persistently abrogate residual HIV production from cellular reservoirs in blood and possibly tissues from virally suppressed subjects. Our experiments provide a proof-of-concept for the use of transcriptional suppressors in novel therapeutic strategies with the long-term goal of obtaining a functional cure for HIV.

380 Mechanisms by Which Negative Elongation Factor (NELF) Establishes and Maintains HIV Latency
Gillian M. Schiralli Lester1, Malini Natarajan2, Andrew J. Henderson1
1Medicine, Infectious Disease, Boston University Medical Center, Boston, MA, United States, 2Stowers Institute for Medical Research, Kansas City, MO, United States

Background: Understanding events which contribute to HIV latency is critical for improving current treatments and potentially eradicating HIV infection. Events that contribute to HIV latency include repressive chromatin structure, transcriptional interference, the inability of Tat to recruit P-TEFb and poor processivity of RNA polymerase II (RNAP II). Previously, we have established an important role for promoter proximal pausing in regulating HIV transcription. In this study we investigate whether RNAPII pausing is operative in the context of different cell models of latency, including transcriptional interference. Our data support that RNAPII pausing via NELF recruits co-repressor complexes and transcription factors which influence T cell commitment to repress HIV transcription.

Methodology: We have identified novel NELF interacting factors via Mass Spec analysis and have used immunoprecipitation and ChIP analysis to verify physical and functional interactions. We utilized multiple infected cell models including HIV infected Jurkat T cells, the latently infected ACH2 cell line, latently infected transcriptional interference cell lines and primary CD4+ T cells to further investigate NELF's involvement in HIV transcriptional latency.

Results: We have identified novel NELF interacting partners NCOr1-GPS2-HDAC3, a known co-repressor complex, and Bcl11b, a T cell commitment factor. HDAC3, GPS2 and Bcl11b bind latent HIV LTR. When the latent HIV LTRs are induced with PMA binding of these factors to the LTR is diminished. In addition, we have investigated NELF's involvement in regulating HIV transcription in cell lines where the latent HIV LTR is integrated into a transcriptionally active gene, resulting in transcriptional interference of the provirus. Treatment of these cell lines with a HDAC inhibitor such as TSA did not induce HIV transcription, however, when we knock down NELF in this model HIV transcription is induced. Furthermore, overcoming HIV proviral transcriptional interference correlates with diminished NELF binding to the HIV LTR.

Conclusions: Our data indicate that NELF is coordinating multiple mechanisms responsible for transcriptional silencing of the HIV LTR. Key factors involved in NELF induced repression of the provirus are NCOr1-GPS2-HDAC3 and Bcl11b. NELF coordinates chromatin organization through the NCOr1-GPS2-
HDAC3 complex and the recruitment of Bcl11b. These data support that RNAPII pausing is a major checkpoint in the establishment of HIV latency and a potential target by which to purge latent HIV reservoirs.

381 Differential Role of Bromodomain Proteins in HIV-1 Latency

Daniela Boehm, Pao-Chen Li, Hendrik Sy, Melanie Ott
Gladstone Institute of Virology and Immunology, Gladstone Institute/University of California San Francisco, San Francisco, CA, United States

**Background:** Small molecules targeting bromodomains (BRD) proteins, a well-conserved class of transcriptional regulators distinguished by the presence of bromodomains, have recently emerged as novel epigenetic therapeutics in hematological and virological disease. Bromodomains are small helical interaction modules that specifically bind acetylated lysines in histones and nonhistone proteins. We recently tested the effect of bromodomain inhibitors JQ1, I-BET, I-BET151 and MS417 on HIV latency. We and others showed that these compounds effectively reactivate HIV from latency in cell culture cells and select primary T cell models of latency. We hypothesize that bromodomain inhibitors target BRD proteins to neutralize their suppressive action and activate HIV from latency.

**Methodology:** We performed a comprehensive lentiviral shRNA screen of BRD proteins in J-Lat cells to identify which BRD protein is involved in the regulation of HIV latency. We also performed co-immunoprecipitation experiments to test for interaction of P-TEFb and BRD proteins.

**Results:** We tested two independent shRNAs against BRD1-9 in J-Lat A2 and A72 cells and tested reactivation from latency by flow cytometry of GFP with and without JQ1. Knockdown of BRD8 resulted in activation of the HIV LTR, similar to activation observed with BRD2 knockdown, however, this reactivation was still responsive to JQ1. In contrast, knockdown of BRD3 resulted in a decrease of basal HIV transcription, and the activatory potential of JQ1 was unchanged. Co-treatment of cells with JQ1 and DBR, a CDK9 inhibitor, resulted in a decreased ability of the cells to respond to JQ1 treatment. Similar results were observed when Cyclin T1 was knocked down with two independent Cyclin T1 shRNAs, indicating that the JQ1 effect in latent cells requires intact P-TEFb.

In co-immunoprecipitation experiments we found that BRD2, which lacks a bone-fide P-TEFb interacting domain and has not been associated with P-TEFb-binding, efficiently co-immunoprecipitated with the P-TEFb component Cyclin T1, an interaction that was enhanced in the presence of JQ1. This interaction also depended on intact acetylation sites in Cyclin T1, indicating that BRD2 interacts with P-TEFb via acetylated Cyclin T1 and the BRD2 bromodomain.

**Conclusions:** Our data indicate that bromodomain inhibitors activate HIV latency by a Tat-independent mechanism and implicate a thus far unrecognized bromodomain family member BRD8 in the establishment and/or maintenance of HIV latency. Further, we confirm BRD2 as a candidate target of bromodomain inhibitors in the reversal of HIV latency.

382 The NCOR2-Nurr1-CoREST Axis Impairs HIV Reactivation in Latently Infected Microglial Cells

David Alvarez, Biswajit Das, Yovelis Garcia-Mesa, Curtis Dobrowolski, Jonathan Karn
Molecular Biology and Microbiology, Case Western Reserve University, Cleveland, OH, United States

**Background:** Whereas the incidence of HIV-associated dementia (HAD) has declined due to successful anti-retroviral treatments, prevalence of milder forms of HAD, which include asymptomatic neurocognitive impairment (ANI) and minor neurocognitive disorder (MND) has increased. Both ANI and MND are part of what is known as HIV-associated neurocognitive disorders (HAND). However, the molecular mechanisms explaining regulation of HIV activation in the brain remain ill-defined. The Nurr1/CoREST transregression pathway has been recently described as a regulator of glial cells response to brain inflammation by limiting over-reactivation of NF-κB-dependent pro-inflammatory genes.

**Methodology:** Microglial cell culture, pharmacological inhibition, shRNA-mediated knockdown, and chromatin immunoprecipitation/sequencing.

**Results:** We report here that, unlike in latently-infected T-cells, in latently-infected microglial cells (CHME-5/HIV), HIV is induced by pharmacological inhibitors of the CoREST complex chromatin-modifying enzymes LSD1 and G9a/GLP; these inhibitors also sensitized CHME-5/HIV cells for LPS or IL-1β-mediated HIV reactivation. shRNA-mediated knockdown of Nurr1, LSD1, or CoREST yielded similar results. Chromatin immunoprecipitation analysis followed by high throughput next generation sequencing revealed that upon microglia treatment with TNFα, the nuclear receptor co-repressor 2 (NCOR2/SMRT), which strongly interacts with Nurr1 to facilitate transrepression, is present at the HIV promoter before activation, then recruited at the earliest time points, and then its presence fluctuates over time. Likewise, Nurr1, CoREST, LSD1, and G9a are recruited to the HIV promoter, changing the epigenetic signature (lower H3K4Me/higher H3K9Me2). The repressor role of these proteins in regulating HIV emergence from latency has been confirmed by unbiased shRNA screens for factors involved in maintaining HIV silenced in latently-infected microglial cells.

**Conclusions:** Our data indicate that the NCOR2-Nurr1-CoREST axis plays a role in preventing HIV over-reactivation in microglial cells, and studying this mechanism in detail may provide therapeutic targets for the treatment of HAND.

383 Repression of HIV Transcription in Memory CD4+ T Cells by Blimp-1

Katarzyna Kaczmarek1, Malini Natarajan1, Zaida Euler2, Gailt Alten3, Andrew J. Henderson1
1Molecular and Translational Medicine, Boston University School of Medicine, Boston, MA, United States, 2Stowers Institute for Medical Research, Kansas City, MO, United States, 3Ragon Institute of MGH, MIT and Harvard, Boston, MA, United States

**Background:** A barrier to eradicating HIV infection is targeting and eliminating latently infected memory CD4+ T cells, which are the main reservoir of latent virus. Our goal is to determine if T cell specific transcription factors restrict HIV transcription in specific T cell subsets to establish and maintain HIV latency. The transcription factor B Lymphocyte-Induced Maturation Protein 1 (Blimp-1) is expressed in B and T cells and upregulated in patients chronically infected with HIV. Blimp-1 inhibits IL-2 transcription and the IL-2 promoter and the HIV long terminal repeat (LTR) share common cis-elements. We hypothesize that Blimp-1 binds to the HIV LTR, inhibits HIV transcription and contributes to HIV latency.
Methodology: We used T cell lines and primary human CD4+ T cells to study the role of Blimp-1 in HIV transcription. HIV replication was monitored using luciferase reporters, RT-PCR, and HIV p24 ELISA assays. Binding of Blimp-1 to the HIV LTR was determined using chromatin immunoprecipitation assay. Blimp-1 expression was diminished using shRNA. The levels of Blimp-1 in different T cell subsets were measured using flow cytometry and immunobLOTS.

Results: We show that Blimp-1 is expressed in primary peripheral blood CD4+ T cells and is further induced by T cell activation. However, infection of CD4+ T cells with HIV induces the induction of Blimp-1. Importantly, Blimp-1 is differentially expressed in T cell populations and in particular is highly expressed in memory CD4+ T cells which do not support robust HIV replication. Ectopic expression of Blimp-1 in CD4+ T cells represses HIV transcription, whereas decreasing Blimp-1 in memory CD4+ populations activates HIV transcription. Blimp-1 binds downstream of the HIV 5’-LTR in resting primary CD4+ T cells and represses Tat-dependent HIV transcription. Upon T cell activation with anti-CD3 and anti-CD28 antibodies Blimp-1 is released from the HIV LTR and this correlates with significant increase in HIV transcription.

Conclusions: We propose a model in which Blimp-1 acts as an HIV restriction factor in memory CD4+ T cells through binding downstream of the HIV LTR and remodeling chromatin. Intrinsic inhibitors of HIV transcription, such as Blimp-1, may provide novel therapeutic targets for purging latent virus from specific cells.

384 HIV-1 Reactivation and Autophagy Inhibition Synergize To Cell Death via Amino Acid Deprivation

Metodi V. Stankov1, Diana Panayotova-Dimitrova2, Georg M. N. Behrens2
1Department for Clinical Immunology and Rheumatology, Hannover Medical School, Hannover, Germany; 2Department of Dermatology, Venerology and Allergology, Mannheim Clinic of University of Heidelberg, Mannheim, Germany

Background: Reactivation of latent provirus is considered a critical approach in modern strategies to purge latent HIV reservoir. Although histone deacetylase inhibitors (HDACi) demonstrated promising results in HIV virus reactivation, the killing of the infected cells, which appears to be a key step in the elimination of HIV reservoir, remains an issue. Recently the cellular degradation pathway of autophagy, an essential process allowing cells to survive amino acid deprivation has been implicated in HIV viral cycle and homeostasis. We hypothesized that latent HIV-1 reactivation as well as autophagy inhibition may sensitize infected cells to amino acid deprivation.

Methodology: Analyses were performed using latently infected cell lines J-lat full length clones (6.3; 8.4; 9.2; 10.6; 15.4) expressing HIV-R7/E-/GFP. Provirus reactivation was achieved using sodium valproate (VPA) (0.4, 2 and 10mM), vorinostat (SAHA) or panobinostat (Pano)(0.4, 2 and 10μM). Autophagy was inhibited using 3-MA (3 -10mM), LY294002 (7 - 20μM) or chloroquine (CQ)(4 - 100μM). Autophagy was measured using flow cytometry, fluorescent microscopy and western blotting. Apoptosis and cell viability were measured by propidium iodide (PI) nuclear staining, PI exclusion assay, Annexin V staining or by changes of cellular FSC vs SSC.

Results: VPA, SAHA or Pano exposure for 24h induced up to 3 fold (p<0.017), 41 fold (p<0.0001) and 55 fold (p<0.0001) reactivated HIV-1 expression correspondingly. Provirus reactivation appeared on reactivation as it was reduced by co incubation with autophagy inhibitors. SAHA or Pano mediated reactivation of HIV-1 expression (for 14h) rendered cells highly sensitive to CQ induced inhibition of autophagy as additional co incubation with 20μM CQ for 8h synergized with viral reactivation and decreased cellular viability by 2.1% (Control; p=0.057), 61% (SAHA; p=0.057) and 60% (Pano; p=0.072). Importantly upon HIV-1 reactivation, cells appeared unable to survive amino acid deprivation (8h) as this led to a decrease in cell viability by 3.5% (Control; p<0.0001), 47% (SAHA; p=0.0024) and 75% (Pano; p=0.0022). The level of provirus reactivation nicely correlated with sensitization to amino acid deprivation. Furthermore CQ exposure synergized with provirus reactivation in sensitizing cells to amino acid deprivation.

Conclusions: Autophagy inhibition synergizes with HIV-1 cytopathic effects upon latent HIV-1 virus reactivation. Latent HIV-1 reactivation sensitized the infected cells to amino acid deprivation, which was further exacerbated by CQ mediated suppression of autophagy. These in vitro results may serve as a proof of concept study opening an avenue for the development of new strategies for the elimination of latent HIV reservoir upon reactivation.

385 JAK Inhibitors Tofacitinib and Ruxolitinib Block T-Cell Activation Mediated HIV Replication

Franck P. Dupuy4, Jessica Brehm1, Christina Gavegnano1, 2, Raymond F. Schinazi3, Rafick P. Sekaly1
1Vaccine and Gene Therapy Institute, 2The Emory Transplant Center, 3Antiviral Research, 4Department of Pediatrics, Center for AIDS Research, Laboratory of Biochemical Pharmacology, Atlanta, GA, United States; 2Department of Pediatrics, Center for AIDS Research, Laboratory of Biochemical Pharmacology, Atlanta, GA, United States, 3Veterans Affairs Medical Center, Decatur, GA, United States

Background: Despite the successful suppression of plasma viremia, persistent immune activation and inflammation in HIV infected is associated to HIV persistence and increased morbidity. Targeting immune activation/inflammation using JAK inhibitors represents a rationale way to reduce inflammation-driven residual viral replication and/or viral persistence due to homeostatic proliferation. Tofacitinib and ruxolitinib are FDA-approved Jak1/2 inhibitors for treatment of rheumatoid arthritis and myelofibrosis; we evaluated them for their ability to block cytokine-mediated activation of JAK/STAT signaling pathway(s), T-cell activation and viral replication in HIV-infected primary human lymphocytes.

Methodology: We developed two models to evaluate the impact of Jak inhibitors on viral production/replication and T cell activation. In the ex vivo model, CD4 T-cells isolated from viremic subjects were stimulated for 3-6 days with anti-CD3/28, +/- antiretroviral agents and increasing concentrations of Jak inhibitors. In the in vitro model, CD4 T-cells isolated from healthy subjects were treated with increasing concentrations of inhibitors (0.1-10 μM) for 3-6 days after infection with HIV-1 NL4-3-GFP. Viral production was quantified by p24-ELISA or by evaluating the frequency of GFP+ cells using FCM. HIV-1 co-receptors and markers for T-cell activation and proliferation were measured by FCM.

Results: Addition of tofacitinib and ruxolitinib to primary CD4 T cells from HIV infected subjects or cells infected ex vivo demonstrated a concentration dependent reduction of HIV production and replication in both models (EC50 0.1 μM, p < 0.05). Inhibitor concentrations ≥ 0.01 μM demonstrated more than 50% inhibition of anti-CD3/CD28 induced activation/proliferation of CD4 cells (CellTraceTM Violet low, CD38, CD25, CCR5, HLA-DR,PD-1) and >50% inhibition of viral production measured by p24 (p < 0.05). Exogenous addition of 10-100 ng/mL IL-2 overcomes inhibition of cell activation and viral
production mediated by Jak inhibitors at < 0.03 μM suggesting that these inhibitors act either by increasing levels of CCR-5, by expanding the number of cells producing virus or by protecting these cells from death.

Conclusions: Tofacitinib and ruxolitinib at physiologically relevant concentrations inhibited multiple signaling pathways associated with viral persistence. Selective blocking of JAK/STAT signaling pathway(s) could prevent persistence of cells producing virus, thereby reducing viral reseeding and reservoir size mediated by persistent immune activation and inflammation leading to a functional cure.

386LB Human Genome shRNA Screen Identifies Cellular Factors Controlling Latency

Shweta Hakre1, Martin Kampmann2, Nina N. Hosmane1, Michael C. Bassik3, Erik Verschueren4, Emilie Battivelli5, Robert F. Siliciano6, Nevan J. Krogan7, Jonathan S. Weissman2, Eric Verdier2

1Virology and Immunology, Department of Medicine, UCSF, Gladstone Institutes, UCSF, San Francisco, CA, United States, 2Cellular and Molecular Pharmacology, Howard Hughes Medical Institute, University of California, San Francisco, CA, United States, 3Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, United States, 4Genetics, Stanford University School of Medicine, Stanford, CA, United States, 5Cellular and Molecular Pharmacology, University of California, San Francisco, CA, United States, 6Virology and Immunology, Gladstone Institutes, UCSF, San Francisco, CA, United States, 7Medicine, Howard Hughes Medical Institute, Johns Hopkins School of Medicine, Baltimore, MD, United States, 8Virology and Immunology, Cellular and Molecular Pharmacology, UCSF, Gladstone Institutes, UCSF, San Francisco, CA, United States, 9Virology and Immunology, Department of Medicine UCSF, Gladstone Institutes, UCSF, San Francisco, CA, United States

Background: There is a “silent” population of HIV infected cells that remains in the host even after anti-retroviral therapy. This “silent” or latent population prevents the eradication of HIV in treated patients. Several mechanisms have been proposed to explain HIV latency. In order to identify the full set of cellular factors that control HIV latency, we have used a systems biology approach.

Methodology: A human genome-wide shRNA library containing 25 shRNAs per gene and a complexity of 495,000 shRNAs was transduced in a Jurkat T cell model for HIV latency (J-Lat). This cell line contains a latent HIV genome with a GFP reporter. The shRNAs contain an mcherry marker for easy identification. GFP and mcherry containing double positive cells were sorted by FACS after transduction of the library. DNA was extracted from the double positive population and from the unfractionated population and analyzed by deep sequencing for the presence of unique shRNAs. shRNAs were found to be either enriched or disenriched.

Results: The screen yielded several genes that have been previously reported in controlling HIV latency as well as HIV transcription. These included single genes such as MBD2, Eed and CHD1 and protein complexes such as Nurd complex and the Polycomb group complex (PrC2). Notably, the p-TEFB complex, which is the most well known positive regulator of HIV transcription, was also identified. In addition to known genes and complexes, there were also several unknown factors. These included factors that controlled T cell activation, differentiation of T cell subsets as well as T cell cytoskeletal rearrangement among others. Some of these factors have been further confirmed both in the J-Lat model as well as the primary latency model.

Conclusions: The human genome wide shRNA screen yielded a broad map of the genes, complexes and pathways that could be controlling the maintenance as well as the exit from HIV latency. These novel complexes could serve as useful drug targets to test in future studies involving patient samples.

Dynamics of Persistent and Rebound HIV

387 Incomplete Adherence To cART Is Associated With Higher Levels of Residual HIV-1 Viremia

Jonathan Z. Li1, Sebastien Gallien2, Heather Ribaudo1, Andrea Heisey1, David R. Bangsberg3, Daniel R. Kuritzkes4

1Brigham and Women’s Hospital, Harvard Medical School, Boston, MA, United States, 2Hôpital Saint Louis, Paris, France, 3Harvard School of Public Health, Boston, MA, United States, 4Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States

Background: The persistence of HIV-1 in the latent reservoir is reflected in the frequent detection of residual HIV-1 viremia below 50 copies/mL despite long-term antiretroviral therapy (ART). Incomplete ART adherence is common even in individuals who maintain virologic suppression <50 copies/mL, but its effect on residual viremia is unknown. We hypothesize that incomplete ART adherence may lead to active viral replication and higher levels of residual HIV-1 viremia, even for individuals with apparently successful virologic suppression.

Methodology: Medication adherence and residual viremia <50 copies/mL were quantified in participants of the REACH cohort of homeless and marginally housed individuals with HIV/AIDS. Participants (N=64) had at least 6 months of virologic suppression <50 copies/mL and were in the adherence monitoring cohort with unannounced pill counts on a random day at the participants’ usual place of residence every 3-6 weeks. Residual viremia was measured by the single-copy assay.

Results: The median duration of virologic suppression was 10.5 months [Q1-Q3: 7.5-18.4 months] and the median average ART adherence over the prior 1 and 2 months was 94% [Q1-Q3: 79%-100%] and 93% [Q1-Q3: 82%-98%], respectively. Average ART adherence over the past 2 months was associated with levels of residual HIV viremia (Spearman r = -0.25, P=0.04). One-third of participants with 100% ART adherence over the previous 2 months had detectable residual viremia. In multivariate regression analysis, ART adherence over the past 2 months, but not duration of virologic suppression, CD4+ T cell count, or ART regimen, was significantly associated with levels of residual HIV-1 viremia (P=0.004). Detectable residual viremia was associated with virologic failure (>50 copies/mL) in univariate Cox proportional hazard analysis (HR 2.08, P=0.02). However, in multivariate analysis, only ART adherence was associated with risk of virologic failure (HR 1.21, P<0.001).

Conclusions: Incomplete ART adherence was associated with higher levels of residual HIV-1 viremia, which may reflect new rounds of HIV replication even when an individual’s viral load is <50 copies/mL. However, residual viremia was also detected in some individuals despite 100% measured ART adherence, suggesting that a component of residual viremia may originate from ongoing release of HIV-1 from the latent reservoir.
388  **Viral Dynamics of HIV-1 Rebound Viremia**

**Benjamin Scheinfeld, Katharine J. Bar**

*Medicine, University of Pennsylvania, Philadelphia, PA, United States*

**Background:** When combination antiretroviral therapy (cART) is initiated in chronic HIV-1 infection, virus quickly rebounds to near pre-treatment levels. The functional latent reservoir is challenging to measure during suppressive cART; rebound HIV-1 virus populations arise directly from the functional latent reservoir, are the actual viruses that curative strategies need to interdict and may be more readily defined. Here, we report a pilot study using single genome sequencing on plasma samples obtained shortly after cART interruption to characterize the clonality and kinetics of rebound virus populations arising from latency.

**Methodology:** We performed single genome sequencing on plasma samples obtained from four deidentified HIV-1 infected subjects who underwent analytical treatment interruption through other protocols. Viral RNA was extracted, cDNA synthesized and limiting dilution PCR performed to amplify HIV-1 env sequences. Sequences were aligned and analyzed phylogenetically.

**Results:** Between 20 and 30 gp160 or gp41 env sequences were generated from the first vRNA-positive plasma obtained after treatment interruption (during ramp-up), and 4, 8 and 12 weeks subsequently. Virus populations from the first vRNA-positive sample had maximum diversities ranging from less than 1% to greater than 5% diversity. Phylogenetically, sequences clustered into distinct low-diversity lineages, each indicating origin from a single latently infected cell or rebound founder population. The four subjects had 4, 4, 8 and >10 distinct founder populations, respectively. Over 12 weeks, founder virus populations expanded rapidly due to the introduction of novel founder virus populations and recombination. Strikingly, we observed complete replacement of initial virus populations with genetically distinct virus populations in some subjects.

**Conclusions:** Our findings demonstrate that single genome sequencing can be used to identify and characterize rebound founder virus populations. Despite earlier reports suggesting a mono- or oligoclonal viral population during initial rebound viremia (Joos et al., PNAS 2008), we found a greater range in numbers of founder populations during virus ramp-up in the first days to weeks after treatment interruption. Further, rebound founder virus populations expanded more rapidly than previously suggested. We also identified complete replacement of initial virus populations indicative of potent immunological sweeps in the first weeks post-treatment interruption. The study of rebound founder virus populations is a novel strategy to characterize the functional latent reservoir and the immune pressures present upon treatment interruption, both of which have great relevance to curative efforts.

389  **Transcripts Associated With the HIV Reservoir Correlate With the Pool Size of Long-Lived CD4 T Cells**

**Maria J. Buzon1,2, Guoyang Zhengyu1, Amy Shaw1, Hong Sun1, Forencia Pareyre1,4, Nadine Zangger1, Xu Yu1, Amalio Telenti3, Eric S. Rosenberg2, Matthias Lichterfeld2**

1Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States, 2Infectious Disease Division, Massachusetts General Hospital, Boston, MA, United States, 3AIDS Research Center, The First Affiliated Hospital of China Medical University, Shenyang, China, 4Infectious Disease Division, Brigham and Women’s Hospital, Boston, MA, United States, 5Institute of Microbiology, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland

**Background:** Although active HIV-1 replication can be effectively suppressed by antiretroviral therapy (ART), the virus persists despite treatment and rapidly rebounds once treatment is discontinued. Prolonged ART initiated early after infection has been shown to reduce the size of the HIV-1 reservoir, however it does not eradicate the viral infection. This long-term viral persistence is mainly due to the presence of latently infected CD4 T cells, but host factors that modulate the size of the latent viral reservoir are incompletely understood.

**Methodology:** CD4+ cells were sorted after a median of 10 years of undetectable viremia from 37 treatment-naive Elite Controllers (EC), 10 patients who initiated ART in the chronic phase of infection (CT) and 8 patients initiating ART within 90 days of infection (ET). Following mRNA extraction, whole-genome transcriptional profiling was performed using Illumina HumanHT-12 microarrays according to standard procedures and differentially expressed genes were defined as having >1.5-fold differences in gene expression intensity and an FDR-corrected p-value of < 0.05. A linear regression model in R was used to identify gene transcripts associated with viral reservoir size in CD4 T cells.

**Results:** Principal component analysis suggested that long-term ART initiated in primary HIV-1 infection induced gene expression patterns in CD4 T cells that closely resemble those of EC. Notably, linear regression analysis demonstrated that 163 out of 215 of the differentially-expressed transcripts between ET and CT were negatively correlated to the total viral reservoir size (HIV-1 DNA copies/cell) in total CD4 T cells. Interestingly, many of the transcripts associated with the viral reservoir size in total CD4 T cells were also significantly correlated to the relative proportion of CD4 T memory stem cells and of central-memory cells within the total CD4 T cell pool, but with not any other tested immunological characteristics of the patients, including total CD4 T cell count or levels of immune activation in CD4 or CD8 T cells.

**Conclusions:** Gene transcripts associated with the size of the viral reservoir frequently correlated with the pool size of the long-lived CD4 T cells, suggesting that maintenance of the viral reservoir is guided by shared molecular pathways that also regulate homeostasis and pool size of these long-lasting T cell populations. This suggests that specific therapeutic intervention targeting the most durable CD4 T cell subsets will likely be necessary to reduce HIV-1 persistence in a clinically significant way.

390  **Massive Expansion of HIV Infected Cells With Identical Proviruses in Patients On Suppressive ART**

**Mary Kearney1, Luke Smith1, Johnathan Spindler1, Charles Coomer1, Guillaume J. Besson2, Elizabeth M. Anderson1, Wei Shao2, John M. Coffin3, John W. Mellors4, Frank Maldarelli5**

1National Cancer Institute, NIH, Frederick, MD, MD, United States, 2University of Pittsburgh, Pittsburgh, PA, United States, 3Advanced Biomedical Computing Center, SAIC, Frederick, MD, MD, United States, 4Department of Molecular Biology and Microbiology, Tufts University, Boston, MA, United States, 5Department of Medicine, University of Pittsburgh, Pittsburgh, PA, United States

**Background:** Studies of HIV-1 population genetics during ART have shown the emergence of groups of identical sequences in plasma and PBMCs after long-term suppression. To investigate the mechanisms for the emergence of identical sequences on ART, we identified 14 patients with clonal HIV sequences during long-term therapy and determined their relationship to CD4+ T cell count and HIV DNA copy number.
**Methodology:** Single-genome pro-pol sequences from PBMCs were obtained from 14 subtype B-infected patients at the time of initiating ART and during suppression for 4-12 years. Clusters of identical sequences were identified and the proportions of identical sequences were plotted against baseline and change in CD4+ T cell count and the HIV DNA copy number. Estimates for the total number of CD4+ T cells with clonal proviruses were determined by multiplying the fraction of identical sequences by the normalized HIV DNA copy number and the estimated total body CD4+ T cells.

**Results:** The fraction of identical sequences in PBMCs during long-term ART ranged from 7% to 55% of the total HIV DNA. In 3/13 patients who started therapy during chronic infection with T cell counts <100/ul, there was an apparent positive relationship between the change in CD4+ T cells following ART initiation and the emergence of identical sequences and a negative relationship with the HIV DNA copy number. There was no obvious relationship between the CD4+ T cell count or the HIV DNA copy number in patients who initiated ART during chronic infection with >100 CD4+ T cells/ul or in patients who initiated ART during early infection. Estimates of the total body number of CD4+ T cells carrying clonal HIV sequences ranged from 1.3x10⁹ to 6.9x10¹⁰.

**Conclusions:** Analyses of the genetics of HIV proviruses during ART suggests a relationship between the change in CD4+ T cell count and the total DNA copy number with the emergence of identical sequences during therapy in those patients initiating ART with very low CD4+ T cell copy number. This finding suggests that increasing numbers of CD4+ T cells on ART is due, in part, to the expansion of infected cells. Estimates on the number of CD4+ T cells carrying identical HIV proviruses suggests that infected cells expand massively before and during ART generating billions of new infected cells from a single initial infection event despite suppressive therapy.

**391 Effects of CCR5-Δ32 Heterozygosity On HIV-1 Reservoir Size and Immune Activation**

Charlene Wang 1, 2, Mohamed Abdel-Mohsen 2, 3, Matthew C. Strain 4, 5, Steven M. Lada 4, 5, Leslie Cockerham 2, Steven Yulk 4, 5, Teri Liegler 2, Douglas D. Richman 4, 5, Steven G. Deeks 5, Satish K. Pillai 2

1Emory University, Atlanta, GA, United States, 2Blood Systems Research Institute, San Francisco, CA, United States, 3University of California, San Francisco, San Francisco, CA, United States, 4Veterans Affairs San Diego Healthcare System, San Diego, CA, United States, 5University of California, San Francisco, San Francisco, CA, United States

**Background:** The CCR5-Δ32 mutation in humans decreases cell surface expression of CCR5. To date, all three reported cases of HIV-1 eradication via bone marrow transplantation have been documented in CCR5-Δ32 heterozygotes. The contribution of CCR5-Δ32 heterozygosity to the observed eradication is as yet unknown. In this study, we examined the impact of CCR5-Δ32 heterozygosity on HIV-1 reservoir size and immune activation. We hypothesized that lower CCR5 cell surface expression may reduce susceptibility to infection by CCR5-tropic viruses, thereby modulating the size of the reservoir, the distribution of infected cell types, and/or the contribution of infection to immune activation and inflammation.

**Methodology:** 18 CCR5-Δ32 heterozygotes and 59 CCR5 wildtype homozygotes from the SCOPE cohort were selected for analysis. Subjects were treatment-naïve upon enrollment in the cohort, had documented pre-treatment plasma viral loads, and were fully suppressed for more than 1 year, with treatment duration of 1-2 years. Cryopreserved PBMCs were enriched for CD4+ T cells prior to nucleic acid extraction. HIV-1 pol and 2-LTR circle DNA were quantified by droplet digital PCR and cell-associated HIV-1 RNA was quantified by ultrasensitive real-time PCR. Flow cytometry was used to measure CD3, CD4, CD8, CCR5, CD38, HLA-DR, and PD-1, and T-cell subset markers on unfractionated PBMCs.

**Results:** The frequency of CCR5-positive CD4+ T cells (p=0.016) and CCR5 mean fluorescence intensity (MFI) (p=0.027) were significantly lower in CCR5-Δ32 heterozygotes compared to wildtype individuals. Cell-associated HIV-1 RNA was significantly lower in CCR5-Δ32 heterozygotes (p=0.047), despite similar levels of pol and 2-LTR circle DNA in both genotype groups. Cell-associated HIV-1 RNA was positively correlated with CCR5 MFI (r²=0.12, p=0.003) and frequency of HLA-DR+ CD38+ CD4+ T cells (r²=0.09, p=0.001), and inversely correlated with frequency of CD4+ T cells (r²=0.17, p<0.0001) across the entire cohort of both CCR5-Δ32 heterozygotes and wildtype individuals. CCR5 MFI was positively correlated with frequency of HLA-DR+ CD38+ CD4+ T cells (r²=0.46, p<0.0001).

**Conclusions:** Reduced HIV-1 RNA expression despite similar HIV-1 DNA levels indicates that the average per cell transcription of HIV-1 is likely reduced in CCR5-Δ32 heterozygotes. The molecular and mechanistic basis for this suppression should be explored in greater detail. Correlations between cell-associated HIV-1 RNA and both cellular activation and CCR5 expression suggest that reduced CCR5 availability in CCR5-Δ32 heterozygotes may limit the size of the functional HIV-1 reservoir and decrease immune activation, thereby enhancing the probability of achieving viral eradication.

**392 Seminal CMV Replication, Immune Activation, and Higher Proviral HIV DNA During Suppressive ART**

Sara Gianella 1, Marta Massanella 1, Douglas D. Richman 2, 3, Susan J. Little 1, Celsa A. Spina 2, Eric S. Daar 2, Michael P. Dube 4, Richard H. Haubrich 1, Sheldon R. Morris 1, Davey M. Smith 1, 5, and the CCTG 592 Team.

1Medicine, University of California San Diego, La Jolla, CA, United States, 2Veterans Affairs San Diego Healthcare System, San Diego, CA, United States, 3Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA, United States, 4University of Southern California Keck School of Medicine, Los Angeles, CA, United States, 5Veterans Affairs San Diego Healthcare, San Diego, CA, United States

**Background:** CMV replication is frequent in the genital tract of HIV infected men, and is associated with increased immune activation and HIV disease progression. We hypothesized that CMV-associated immune activation could influence the size of the HIV DNA reservoir during suppressive antiretroviral therapy (ART).

**Methodology:** Paired blood and semen samples from 53 HIV infected men on long-term ART with undetectable HIV RNA in blood plasma were studied. Levels of CMV DNA were measured in seminal plasma by RT-PCR. Total HIV DNA (pol), 2-long terminal repeat (2-LTR), and cellular HIV RNA (unspliced [us] gag and multiply-spliced [ms] encoding for tat/rev) were measured in peripheral blood mononuclear cells (PBMC) by droplet digital PCR. Levels of CD4+ and CD8+ T-cells immune activation (CD38+HLA-DR+) and proliferation (Ki67+) were determined from PBMC by multicolor flow-cytometry. Associations between levels of proviral HIV DNA, cellular HIV RNA, immune activation and proliferation in blood, time on ART, CD4+ T-cells counts and the presence of CMV replication in semen were investigated using univariate and multivariate non-parametric statistics.
Results: Detectable CMV DNA was found in 44% of seminal samples, and was associated with higher levels of proliferating (Ki67+) and activated (CD38+HLA-DR+) CD4+ T-cells (P<0.01), and a trend towards higher levels of proliferating CD8+ T-cells (P=0.1) in blood. Subjects with detectable seminal CMV had higher levels of proviral HIV DNA (2.84 versus 2.11 log10 copies/million CD4+, P=0.05) and higher levels of cellular [ms] HIV RNA (P=0.04) compared to those without seminal CMV. Levels of [us] HIV RNA, 2-LTR and average cellular transcription (i.e. cellular HIV RNA/DNA ratio) were not different between subjects with and without CMV. There was a weak correlation between seminal CMV DNA and CD4-associated HIV DNA levels (P=0.06, r=0.26). Among subjects with detectable CMV in semen, there was a significant correlation between HIV DNA levels and frequency of activated (P<0.01, r=0.6) and proliferating CD4+ T-cells (P<0.01, r=0.64). In multivariate analysis, presence of seminal CMV (P=0.04), and detectable 2-LTR (P<0.01) were independent predictors of higher HIV DNA in PBMC.

Conclusions: Asymptomatic seminal CMV replication is associated with higher levels of systemic CD4+T-cell immune activation and proliferation and with a greater size of the HIV DNA reservoir in PBMC. Average HIV transcription was not increased in CMV positive samples, suggesting that CMV is not directly associated with low-level HIV replication but more likely with homeostatic proliferation of HIV-infected CD4+ T-cells. Interventions aimed at reducing seminal CMV replication and associated immune activation could be important for HIV curative strategies.

393 Persistent HIV in Plasma During cART Can Lead To Rebound Viremia After Treatment Interruption

Juniko Hattori1, Wei Shao1, Shawn Hill1, Francesco R. Simonetti1, Elizabeth M. Anderson1, Catherine A. Rehm2, Sara E. Jones2, Richard T. Davey2, Frank Maldarelli2
1HIV Drug Resistance Program, National Cancer Institute, Frederick, MD, United States, 2Advanced Biomedical Computing Center, SAIC-Frederick, Frederick National Laboratories for Cancer Research, Frederick, MD, United States, 3National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, 4Clinical Research Directorate/CMPR, SAIC-Frederick, Inc., Frederick National Laboratory for Cancer Research, Frederick, MD, United States

Background: Combination antiretroviral therapy (cART) suppresses but does not eradicate HIV infection. Analysis of HIV variants during cART has revealed populations of identical sequences, suggestive of clonally expanded populations, which have been found in plasma, in peripheral blood mononuclear cells (PBMC), as well as in anatomic compartments. HIV emerges rapidly after treatment interruption; rebound viremia also includes clonally expanded populations, but it is not known whether these clonal variants arise from persistent viremia during suppression, or from clonal sequences present in PBMC. To investigate the source of early rebound virus, we compared HIV in plasma and cells prior to and following a short structured treatment interruption (STI).

Methodology: Stored plasma and PBMCs were obtained from patients (N=13) with viremia <50 c/ml on cART for ≥1 y enrolled in a STI. PBMCs were on the day of drug interruption, and plasma samples obtained prior to and 1, 4, and 28 days after STI. DNA from PBMC and RNA from plasma was subjected to single genome sequencing (SGS) to obtain pro-RT sequences, which were aligned by Clustal W; phylogenetic analyses were performed using MEGA 5.2.

Results: A total of 13 patients were enrolled (median age 38.7 y, CD4= 611 cells/μl, 39%, duration of suppression 2.7 y prior to STI); 6 patients have been analyzed and 467 SGS obtained thus far. Prior to STI, HIV population structure in PBMC was complex, and included groups of identical sequences in 5 of 6 patients as well as individual variants; viral populations in plasma prior to STI were more restricted with a limited number of variants detected. All patients rebounded within 7-14 days of treatment interruption. As expected, rebound viremia consisted of both individual variants and groups of identical sequences in all patients. In 2 of 6 patients, sequences present during rebound were identical to an HIV variant detected in plasma prior to the STI. In contrast, variants present in rebound viremia were only rarely detected in PBMC-derived DNA.

Conclusions: Early rebound HIV consisted of individual and clonal sequences. PBMC populations were diverse and included clonal sequences. Rebound viremia included clonal sequences, but these populations were distinct from those detected in PBMC, and clonal sequences in PBMC did not give rise to clonal sequences in rebound viremia. These data suggest PBMC associated populations are large and diverse, and rebound viremia likely emerges from a small minority of infected cells. Some variants present in rebound viremia were detected in plasma prior to STI, demonstrating that rebound viremia emerges, at least in part, from expansion of low-level persistent viremia.
Methodology: Eligibility criteria of the New Era Study were CD4 nadir >200/μL, no history of AIDS, CCR5 tropism. PHI pts received 5-drug HAART including 2 NRTIs + 1 PI + Maraviroc + Raltegravir. In CHR pts, HAART was intensified with MVC + RAL. HIV-DNA in peripheral blood mononuclear cells (PBMC) was measured as described by the French ANRS group. Here we describe proviral DNA outcomes and CD38+CD8+ cells at month 24 for PHI and CHR pts stratified by CD4 ≥900/μL and CD4/CD8 ratio ≥1.

Results: In total, 20 CHR and 22 PHI pts were included. PHI pts were started on 5-drug HAART within ≥2.6 weeks after diagnosis. Western blot was negative in 12 PHI pts. 2 PHI pts discontinued before month 24. At month 24, median proviral DNA levels were significantly lower in PHI than in CHR pts (2.1 vs 2.6 log cp/10^6 PBMC, p=0.001). Significantly more PHI pts had a CD4/CD8 ratio ≥1 (90% vs 30%, p<0.001). CD4 count was ≥900/μL in 55% of PHI and 40% of CHR pts (p=n.s.) 50% vs 20% of PHI and CHR pts fulfilled both criteria (p=0.096). Proviral DNA levels and CD8 cell activation are shown in the Table.

Conclusions: In both groups, early treated PHI pts and selective control pts continuously on suppressive HAART, patients with a CD4 cell count ≥900/μL and a CD4/CD8 ratio ≥1 were found. Only for PHI pts, cell-associated HIV-DNA levels were lower in case of normal CD4 count and normal CD4/CD8 ratio supporting that preservation of immune functions during PHI and/or early immune reconstitution are associated with a lower HIV reservoir size and potentially higher rates of PTC.

395 Loss of HIV Serological Markers Following Early Treatment of Acute HIV Infection

Mark M. Manak1, Sheila Peel2, Jennifer Malia3, Ashley Shutt1, Srinwat Akapirat4, Tippawan Pankam4, James Fletcher4, Merlin Robbi5, Jerome Kim6, Jintanat Ananworanich4
1US Military HIV Research Program, HJF, Silver Spring, MD, United States, 2US Military HIV Research Program, WRAIR, Silver Spring, MD, United States, 3Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, 4Thai Red Cross AIDS Research Center, Bangkok, Thailand

Background: Early initiation of highly active antiretroviral therapy (HAART) during acute HIV infection (AHI) may alter the natural history and progression of HIV infection, modify disease outlook and affect the emergence of serological markers of infection. In this study 33 AHI subjects in Bangkok, Thailand in whom HAART was initiated early were followed and tested for serological markers of HIV and compared with a similar AHI population not on early HAART.

Methodology: Volunteer samples were screened for HIV infection by a 4th generation antigen/antibody combo EIA assay. Non-reactive samples were retested by pooled HIV-1 qualitative RNA (Gen-Probe Aptima) assay. Acute HIV infection was classified by Fiebig stage using RT PCR, p24 antigen, EIA, and Western blot assay results. Plasma samples collected at Weeks 0, 2, and 12 were tested by EIA 1/2 Plus O (3rd Gen), HIV-1/2 Ab/Ag Combo (4th Gen), p24 Ag (RUO); HIV-1 Western blot (WB), and Multispot assays (Bio-Rad Laboratories, Inc; Redmond, WA).

Results: Of volunteers who initiated HAART, one Fiebig I (RNA +) volunteer failed to develop a serological response and three others were transiently EIA (3rd Gen) repeat reactive (RR) at Week 2, but reverted to EIA non-reactive (NR) status by Week 12. Two of 15 Fiebig II volunteers were EIA NR, and an additional 2 EIA RR but WB Indeterminate (IND) by Week 12. Of 14 Fiebig III-V volunteers (all EIA RR as defined for these stages), one reverted to EIA NR, three remained WB IND, while one WB positive at Week 2 reverted to WB IND by Week 12. Delayed positivity on the Multispot assay was observed in 10 of 33 individuals. Five volunteers positive by Multispot at Week 2 reverted to negative status by Week 10. In contrast, a similar population of AHI patients that was not on HAART, demonstrated 3rd Gen EIA, 4th Gen EIA and Western blot positivity by Week 2-3; no seroreversions were observed.

Conclusions: Initiation of antiviral therapy at very early stages of infection (Fiebig I) impeded seroconversion to anti-HIV antibody. Initiation of therapy at Fiebig II-V delayed evolution of serological markers as detected by WB and Multispot, and in some cases, resulted in complete seroreversion of initial antibody response. Additional studies investigating initiation of HAART early in AHI on the course of infection and impact on the evolution of serological response is warranted.

396 Early Antiretroviral Therapy Prevents the Establishment of HIV-1 Infection in Humanized-BLT Mice

Qingsheng Li1, For Yue Tso1, Guobin Kang1, Wuxun Lu1, Yue Li1, Wenjin Fan1, Chris J. Destache2, Charles Wood1
1Nebraska Center for Virology & School of Biological Sciences, University of Nebraska-Lincoln, Lincoln, NE, United States, 2Pharmacy Practice, Creighton University School of Pharmacy & Health Professions, Omaha, NE, United States

Background: People who are living with HIV-1 have to maintain a lifetime of antiretrovirals, medication side effects and unsustainable costs to individual and society. Recently, “cure or functional cure” of HIV-1 infections was accomplished with the “Mississippi pediatric case”, proved that curing HIV-1 is
possible. However, the cure treatment window, and the mechanisms of cure are unknown. In this study, curing HIV-1 with early treatment was tested in the humanized-BLT (hu-BLT) mouse model.

**Methodology:** Six adult hu-BLT mice with good immune reconstitution were randomly divided into Early Treatment (Rx, n=3) and Control (Ctr, n=3) groups. Both groups were inoculated intraperitoneally (IP) with a mixture of two transmitted/founder HIV-1 viruses (2.5e3 TCID50 each). Six hours later, animals in the Rx group started daily treatment for two weeks with TDF, 5 mg/mouse, IP and 3TC, 4 mg/mouse, IP; Ctr animals received solvent IP. Three weeks after the antiretroviral drug therapy stopped, CD8+ T cells from both groups were depleted using two dose of anti-CD8 antibody (M-T807R1, 5mg/kg, IP) to test whether undetectable plasma viral load (PVL) was due to CD8+ T cells mediated viral control. Human CD8+ T cells in peripheral blood mononuclear cells (PBMCs) were quantified before and weekly after administration of anti-CD8 antibody using FLOW. Plasma viral RNA load (PVL), monitored weekly post inoculation (PI) using droplet digital PCR (ddPCR). HIV-1 viral DNA in PBMCs was monitored by ddPCR at 5 weeks post-CD8 depletion.

**Results:** Ctr group PVL was positive from 7-10 days PI throughout the entire experiment (mean PVL 6.98e4 copies/mL week 1, increased to 2.5e6 copies/ml at one month PI). In contrast, the Rx group had undetectable weekly PVL, including 3 weeks off therapy. To discriminate CD8+ T cells mediated cure in the Rx group, CD8+ T cells in both groups were depleted. CD8+ T cells comprised 27.6% +/-14.9% of total human CD3+ T cells in PBMCs before administration anti-CD8 antibody. After administration anti-CD8 antibody, 99.5 percent of CD8+ T cells were depleted over 5 weeks. CD8+ T cell depletion significantly increased PVL (mean +SD) in Ctr group (4.0e5 +/- 2.3e4 copies/ml before depletion to 2.7e6 + 2.7e5 at 3 weeks post depletion). In contrast, Rx group PVL remained undetectable and HIV-1 DNA was undetectable in PBMCs.

**Conclusions:** Early antiretroviral treatment can cure transmitted/founder HIV-1 infection in hu-BLT mouse model. Furthermore, CD8+ T cell depletion significantly elevated the PVL in Ctr animals, but did not modify the undetectable PVL in Rx group, suggesting early treatment achieved cure of HIV-1 infection. Studies are ongoing to further define the cure window and mechanisms involved.

### 397LB Lack of Detectable HIV DNA in a PrEP Study Participant Treated During “Hyperacute” HIV Infection

**Hiroyu Hatano**1, Oliver Bacon2, Stephanie Cohen1, Albert Liu1,2, Susan Buchbinder1,2, Nicolas Chomont1, Mary Kearney1, Janet Siliciano2, Teri Liegler1, Steven G. Deeks1

1Medicine, University of California, San Francisco, San Francisco, CA, United States, 2San Francisco Department of Public Health, San Francisco, CA, United States, 3Vaccine and Gene Therapy Institute of Florida, Port Saint Lucie, FL, United States, 4National Cancer Institute, Frederick, MD, United States, 5Johns Hopkins University, Baltimore, MD, United States

**Background:** The study of ART initiation during “hyperacute” HIV infection may provide insights into a functional cure. We report such a case from The PrEP Demo Project, a pre-exposure prophylaxis program in at-risk MSM. This individual was HIV-uninfected (by pooled RNA, 4th generation EIA, and rapid antibody) at 2 pre-enrollment visits (21 and 13 days prior to PrEP baseline) but was found to be in Fiebig stage I HIV infection (RNA 220 copies/mL, 4th generation EIA negative, rapid antibody negative) at the PrEP baseline visit (estimated ~10 days after infection). The individual received PrEP (tenofovir/emtricitabine) for 7 days, at which time PrEP baseline test results returned and conventional ART was initiated. The patient was asymptomatic during this time and remains on ART.

**Methodology:** Single genome sequencing was conducted from the PrEP baseline plasma sample. Colorectal biopsy (~1.9 months after infection) and leukapheresis (~2.1 months after infection) were conducted and a large-volume blood sample (240mL, ~5.8 months after infection) was analyzed for replication-competent virus.

**Results:** Plasma HIV RNA levels were 220 copies/mL (PrEP baseline), 120 copies/mL (7 days after PrEP initiation), and “detected <40 copies/mL” (~32 days after infection); all subsequent plasma RNA levels have remained negative. There was a single occurrence of low-level cell-associated HIV RNA (4.7 copies per million CD4+ T cells) ~32 days after infection. All other HIV RNA/DNA tests have been negative, including those performed in colorectal biopsy samples enriched for total CD4+ T cells. Total CD4+ T cells and CD4+ T cell subsets (Tn, Tcm, Ttm, Tem) from the leukapheresis sample were also negative for HIV RNA and DNA (analyzed at 2 independent laboratories), including total DNA, integrated DNA, and 2-LTR circles. The viral outgrowth assay did not detect any replication-competent virus from 62 million purified resting CD4+ T cells. HIV western blot assays were repeatedly indeterminate (p55 only) but eventually became non-reactive. The individual was CCR5 wild-type and HLAB5701 negative. Analytic treatment interruption is planned after 12 months of ART.

**Conclusions:** We report a case of extremely early initiation of ART (approximately at 10 days after HIV diagnosis) in a PrEP participant. Whether very early ART exposure through PrEP or conventional ART contributed to this unique outcome remains unknown and warrants further study. PrEP programs should consider testing participants for acute HIV prior to and during PrEP use, and consider immediate conversion from PrEP to conventional ART following a diagnosis of acute HIV. Although HIV may persist indefinitely in this individual, a continuum may exist across PrEP, PEP, and cure-adjacent ART strategies.

### 398 Early HAART in Primary HIV Infection Protects TCD4 Central Memory Cells and Can Induce HIV Remission

**Antoine Chéret**1,2, Charline Bacchus3, Adeline Mélard4, Georges Nembot1, Catherine Blanc1, Assia Samri3, Véronique Avettand-Fenoël1, Asier Saez-Cirion5, Brigitte Autran1, Christine Rouzioux1, OPTIPRIM ANRS-147 Study Group

1EA 3620 Paris-Descartes University, Sorbonne Paris-Cité Virology Laboratory, Necker Enfants-Malades Hospital, Paris, France, 2Infectious Diseases Unit, Dron Hospital, Paris, France, 3Pierre & Marie Curie University Paris VI, INSERM UMR-S 945 Immunity & Infection, Pitié-Salpétrière Hospital, Paris, France, 4Epidemiology and Public Health Department, INSERM U1018, AP-HP Le Kremlin-Bicêtre, Paris, France, 5Unite de Régulation des Infections Rétrovirales, Institut Pasteur, Paris, France

**Background:** Post treatment controller status has been associated with a low HIV reservoir, particularly in the CD4 T central Memory. We explored the characteristics of the subsets reservoir after 2 years of early HAART during PHI.

**Methodology:** 12 patients (PHI2) from the OPTIPRIM-ANRS147 trial were enrolled in this substudy (early HAART HIV-1 western-blot (WB) ≤4 antibodies (Ab) and positive HIV-RNA + in case of asymptomatic PHI CD46 years (PHI6) and for 11 post-treatment controllers (PTC) having a viral control for >9 years.
HIV Antibody Characterization To Quantify Reservoir Size During Curative Interventions

Peter D. Burbelo1, Ahmad Bayat2, Craig S. Rhodes1, Rebecca Hoh3, Jeffrey N. Martin3, Gero Hütter4, Joseph A. Kovacs5, Steven G. Deeks6
1NIDCR, NIH, Bethesda, MD, United States, 2Clinical Center, NIH, Bethesda, MD, United States, 3Dept. of Medicine, UCSF, San Francisco, CA, United States, 4Institute of Transfusion Medicine and Immunology, Heidelberg University, Mannheim, Germany, 5Critical Care Medicine Dept., Clinical Center, NIH, Bethesda, MD, United States, 6Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

Background: Since most routine and scalable assays of HIV persistence have sensitivities at or near the level of HIV found in most treated adults, there is intense interest in developing novel methods to characterize viral reservoir during therapy. The host response to residual virus may be a sensitive measure of reservoir size. We quantitatively analyzed the level and distribution of anti-HIV antibody profiles in serum samples of a diverse cohort using Luciferase Immunoprecipitation Systems (LIPS).

Methodology: Using the LIPS assay, antibody responses against nine different recombinant HIV proteins were quantitatively analyzed in uninfected blood donors and five elite controllers as well as in nine HIV-infected adult patients from before and after several years of ART-induced virologic control and in five patients who were cured of their HIV infection following a delta32/delta32 CCR5 stem cell transplant. Heatmap and principal component analysis (PCA) was also used to analyze the antibody data.

Results: At baseline, among the 12 PHI2 (median age: 32 years, time from estimated date of infection: 36 days), 11 were symptomatic, 11 had HIV-1 WB ≤3 Ab; median CD4 counts was 376 cells/mm3 [IQR: 341;516], HIV-RNA 5.4 log cp/ml [5.0;5.8] and HIV-DNA 3.9 log cp/106PBMC [3.48;4.30]. One woman stopped the trial regimen before M24 due to pregnancy. From day 0 to M24, CD4 subset numbers increased (p<0.004) and HIV-DNA median level decreased in PBMC of -1.43 [-1.74;-2.1] (p=0.001), in TN of -0.74 [-0.9;-0.27 ], in TCM of -1.45 [-2.09;-1.34], in TTM of -1.48 [-1.97;-1.23] and -1.34 [-1.81;-1.2] in TEM (all p<0.004). There was no evolution of the viral diversity and viral production was induced by in vitro activation in all CD4 subsets at M24. At M24: long-lived TN and TEM were less infected than TTM and TEM (all p<0.009), less contributed to the reservoir than TTM (p=0.019) while TCM infection level was higher than TN, and similar to the shorter-lived memory subsets at PHI. Despite a significant decrease after 2 years early-HAART, HIV-DNA levels in all CD4 subsets in PHI2 were higher than levels observed in PHI6 and PTC (all p<0.019). Interestingly HIV-DNA levels in PHI6 were similar to those in P2 PHI2 reached a PTC status (HIV-RNA 1 year after treatment interruption), with very low HIV-DNA levels in all CD4 subsets, similar to the11 PTC.

Conclusions: We show that two years of an early treatment during PHI protected the long life TCM and TN from infection. A more prolonged treatment aiming to reach deeper reduction of HIV reservoir would probably more increase the chance to induce cases of patients presenting the characteristics of a HIV functional cure as observed in PTC.

Session P-F4 Poster Session

Methods for Measuring Reservoirs

399LB A Scalable RNA RT-PCR Based Assay To Quantify Latency Disruption in HIV-1 Infected Cells

Jason M. Hataye, Joseph P. Casazza, David R. Ambrozak, Eli Boritz, Takuya Yamamoto, Daniel C. Douek, Richard A. Koup
Vaccine Research Center, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

Background: Antiretroviral therapy (ART) provides suppression of HIV-1 below the limits of standard clinical assays, but virus promptly resurfaces upon interruption of ART due to viral persistence in stable reservoirs. A commonly used method to quantify cells in such reservoirs is HIV DNA PCR due to ease-of-use, however most of these cells are unlikely to ever produce replication-competent virus. On the other hand, viral outgrowth assays provide virologic realism, but are resource intensive. Detection of RNA by RT-PCR is a balanced approach that provides for some virologic realism while allowing for high throughput.

Methodology: Here we describe a method in which flow cytometry purified resting memory CD4+ T cells from ART treated patients are placed in a limiting dilution culture for 4 days in the presence of stimulation with bead-bound antibodies to CD2, CD3, and CD28. Viral replication is inhibited by the inclusion of a non-nucleoside reverse transcriptase inhibitor. The viral RNA is purified from the culture supernatant using a paramagnetic nanoparticle based method that is scalable to robotic automation. The extract is DNase treated and then real time quantitative RT-PCR is performed using a primer and probe set specific for HIV gag. Statistics were performed with the R package for Extreme Limiting Dilution Analysis (ELDA).

Results: This assay is sensitive enough to detect 47 copies of HIV RNA produced from a single activated cell from the ACH-2 HIV latency cell line. Using this method with resting memory CD4+ T cells from virally suppressed patients, the frequency of induced HIV RNA production varied from 1 in 40,000 cells to fewer than 1 in 1,000,000. There was no correlation between frequency of HIV RNA producing cells and frequency of proviral DNA.

Conclusions: This assay represents a scalable bench-to-bedside method for quantifying the frequency of HIV producing cells in the blood and tissues of patients with viral suppression and for evaluating reservoir elimination strategies for such patients.

400 HIV Antibody Characterization To Quantify Reservoir Size During Curative Interventions

Peter D. Burbelo1, Ahmad Bayat2, Craig S. Rhodes1, Rebecca Hoh3, Jeffrey N. Martin3, Gero Hütter4, Joseph A. Kovacs5, Steven G. Deeks6
1NIDCR, NIH, Bethesda, MD, United States, 2Clinical Center, NIH, Bethesda, MD, United States, 3Dept. of Medicine, UCSF, San Francisco, CA, United States, 4Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

Background: Since most routine and scalable assays of HIV persistence have sensitivities at or near the level of HIV found in most treated adults, there is intense interest in developing novel methods to characterize viral reservoir during therapy. The host response to residual virus may be a sensitive measure of reservoir size. We quantitatively analyzed the level and distribution of anti-HIV antibody profiles in serum samples of a diverse cohort using Luciferase Immunoprecipitation Systems (LIPS).

Methodology: Using the LIPS assay, antibody responses against nine different recombinant HIV proteins were quantitatively analyzed in uninfected blood donors (n=10), elite controllers (n=10), HIV-infected adult patients (n=9) from before and after several years of ART-induced virologic control (n=9) and in the Berlin patient who was cured following a delta32/delta32 CCR5 stem cell transplant. Heatmap and principal component analysis (PCA) was also used to analyze the antibody data.

Results: Quantitative humoral profiling of five, recent serial serum samples collected 51-67 months after the transplant from the Berlin patient revealed no antibodies against p24, matrix, nucleocapsid, integrase, protease and gp120, but persistent albeit low levels of antibodies against reverse transcriptase, tat and gp41. In contrast, antibody levels to these HIV proteins persisted at high and stable levels in most non-controllers and antiretroviral-treated subjects. However, five of the ten elite controllers had low levels of antibodies against matrix, reverse transcriptase, integrase and/or protease. PCA and heatmap analysis revealed that the uninfected blood donors and the Berlin patient clustered together and were in close proximity to the five elite controllers with low anti-HIV antibody levels. Since all ten elite controllers showed similar viral loads (<50 copies/ml), these data also highlight the heterogeneity of anti-HIV antibody responses in the elite controllers. Additionally, three of the ART-treated subjects who demonstrated a decrease in HIV antibodies following treatment showed a shift in their PCA profile closer to the uninfected controls following treatment. Across all proteins, responses to gp41 tended to show...
the most consistent group-to-group differences, with increasing responses across the uninfected subjects, the Berlin patient, the controllers and the treated group readily apparent.

**Conclusions:** Monitoring the host humoral response to individual HIV proteins, particularly gp41, may provide a practical tool to longitudinally monitor HIV persistence during curative interventions. The mechanism which accounts for uniquely low levels of antibodies towards certain proteins among some controllers is unknown, but may reflect very low reservoirs.

---

**401 High-Throughput Analysis of Full-Length Proviral HIV-1 Genomes From PBMCs**

Hiromi Imanichi, Fan Guo, Collen Ludaka, Ellen E. Paxinos, H. Clifford Lane, Da Wei Huang, Richard A. Lempicki, Michael P. S. Brown

1 NIAID, NIH, DHHS, Bethesda, MD, United States, 2 Pacific Biosciences, Menlo Park, CA, United States, 3 Leidos Biomedical Research, Inc., Frederick, MD, United States

**Background:** HIV-1 proviruses in peripheral blood mononuclear cells (PBMCs) are felt to be an important reservoir of HIV-1 infection. Given that this pool represents an archival library, it can be used to study virus evolution and CD4+ T cell survival. Accurate study of this pool is burdened by difficulties encountered in sequencing a full-length proviral genome, typically accomplished by assembling overlapping pieces and imputing the full genome.

**Methodology:** Cryopreserved PBMCs collected from a total of 8 HIV+ patients from 1997-2001 were used for genomic DNA extraction. Patients had been receiving cART for 2-8 years at the time samples were obtained. 7 patients had pVL >50 copies/mL (mean: 312,282, range: 18,372-683,400) and 1 had pVL <50. Genomic DNA was subjected to limiting dilution prior to amplification of near-full-length genomes by a newly developed nested PCR. The predicted size of the PCR product was 9.0 kb, spanning from the 5' LTR through the 3' LTR. Single molecules were sequenced as near-full-length amplicons directly from PCR products without shearing using commercially available P4-C2 reagents and standard protocols on a PacBio RS II instrument. Quality of the genomes was validated by clonal positive controls and synthetic mixtures.

**Results:** Near-full-length provirus genome sequences were successfully obtained from all 8 patients as continuous long reads from single molecules. PacBio sequencing required approximately 10% of the PCR product needed for Sanger sequencing and generated 325MB per 3-hour run including 1,800 full-length intact genome reads on average. One patient's sample was not at a limiting dilution and analysis revealed multiple subspecies. For 8 near-full-length provirus genomes derived from the other 7 patients, large internal deletions were noted in 2 proviruses; APOBEC-mediated hypermutations were seen in 2 proviruses; and 4 proviruses appeared to be intact genomes. All of the defective proviruses showed a complete absence of resistance mutations in either RT or protease, even after 2-8 years of cART. On the contrary, all of the intact proviruses contained evidence of ART-resistance associated mutations suggesting that they represented relatively recent variants.

**Conclusions:** Combining a novel protocol for full-length limiting dilution amplification of proviruses with PacBio SMRT sequencing allowed for the generation of near-full-length genomes with good quality and an ability to detect minor variants at the 1-10% level. Preliminary data analyses suggest that defective proviruses may represent archival variants that persist long-term in host cells, while intact proviruses within the PBMC pool showing evidence of active virus replication may represent more recent variants.

---

**402 Using Antibodies To Detect HIV Persistence in Treatment Intensification and Eradication Studies**

Sheila M. Keating, Christopher D. Pilcher, Gary Murphy, Alex Welte, Rreshma Kassanjee, David Matten, Mila Lebedeva, Shelley N. Faenter, Steve G. Deeks, Michael P. Busch

1 Blood Systems Research Institute, San Francisco, CA, United States, 2 UCSF, San Francisco, CA, United States, 3 Public Health England, London, United Kingdom, 4 SACEMA, Stellenbosch, South Africa, 5 Medicine, UCSF, San Francisco, CA, United States

**Background:** Quantifying the degree of HIV persistence during therapy is challenging due to low viral burden and the intracellular sequestration of virus. An alternative or complementary approach is to quantify the host response to HIV. HIV incidence assays have been developed to measure antibody (Ab) evolution during HIV seroconversion. We used HIV incidence assays to investigate the association between HIV Ab levels, avidity and HIV antigen specificities in a diverse cohort of treated and untreated adults.

**Methodology:** HIV incidence assays included: dilution (1:400 dilution in buffer; increased cutoff) for the VITROS® Anti-HIV1+2 assay; an avidity (DEA-incubation/PBS-incubation; avidity index) modification for the BIO-RAD GS HIV-1/2 assay; and an index summing HIV-specific band intensities targeting p31, gp160, gp41 for the Geenius™ HIV1/2 supplemental assay. Using these methods we characterized HIV Ab responses from 280 long-term infected untreated individuals, 280 treated and suppressed individuals, 100 suppressed elite controllers (EC) and one potentially eradicated individual (the Berlin patient). We also observed responses in longitudinal follow-up after HAART.

**Results:** Compared to individuals with untreated HIV infection, EC exhibited lower levels of HIV Ab by both LS-VITROS (p<0.001) and Geenius (p=0.01) quantitative assays, but no difference in antibody avidity by the Bio-Rad avidity assay. EC had higher Ab levels compared to ART-treated suppressed patients in all assays (p<0.001). Subjects treated in acute infection had lower Ab levels on all assays compared to those treated in chronic infection. Among subjects treated with suppressive ART after complete seroconversion, increasing time on treatment was correlated with lower Ab levels by LS-VITROS (p=0.001) and Geenius (p=0.01), but no decline was seen in Ab avidity by the Bio-Rad assay. The Berlin patient has low-level Ab that has progressively declined over time on these assays, consistent with complete absence of virus (eradication).

**Conclusions:** There are reductions in Ab titer but not in avidity in treated compared to untreated individuals that correlates with time on treatment. Although EC had undetectable or very low VL, Ab levels remained elevated compared to individuals on ART, demonstrating maintenance of Ab stimulation from persistent viral replication in reservoirs. Measuring the quantity, quality and diversity of Ab to HIV may be used as a marker for monitoring viral persistence in studies of eradication and treatment.
403LB HIV DNA in PHI Associates With T Cell Immunity and Predicts Disease Progression and Rebound Viraemia

Jacob Hurst1, James Williams1, Elisabeth Hamlyn2, Kersten Koelsch3, Sarah Fidler4, Abdul Babiker4, Jonathan Weber1, Tony Kelleher1, Rodney Phillips1, John Frater1, Spartac Trial Investigators

1University of Oxford, Oxford, United Kingdom, 2Imperial College, London, United Kingdom, 3University of New South Wales, Sydney, United Kingdom, 4MRC Clinical Trials Unit, London, United Kingdom, 5University of New South Wales, Sydney, Australia

**Background:** There are no comprehensive analyses of HIV proviral DNA in Primary HIV Infection (PHI) that include inflammation, HIV-specific immunity and clinical progression. We present analyses from the SPARTAC trial characterizing immunological and virological associations with proviral DNA in PHI, and exploring the impact of proviral DNA on clinical progression and virological rebound on stopping ART.

**Methodology:** Participants with PHI in SPARTAC were analysed for HIV proviral DNA (‘integrated’ and ‘total’ in CD4 T cells), HIV CD4 and CD8 T cell immune responses (by ELISpot), immune activation (HLA DR, CD38), immune exhaustion (TIM-3, Lag-3) and generalized markers of inflammation (D-dimer, IL-6). Outcome measures included time to trial primary endpoint and time to plasma viral load rebound on stopping ART. Statistical associations were determined using linear regression and Cox proportional hazard models.

**Results:** Baseline samples at trial enrolment were available from up to 154 participants with subtype B infection. ‘Integrated’ and ‘Total’ HIV DNA levels were closely correlated (r=0.85; P<0.001) and associated with baseline CD4 count (P<0.001) and plasma viral load (P<0.001). CD8 and CD4 T cell activation (CD38, HLA DR) were significantly associated with HIV DNA (P<0.01), the association being stronger for CD8s. There was a strong association with HIV DNA and D-dimer (P<0.01), but not IL-6. Both CD8 PD-1 and Lag-3 (not TIM-3) were significantly associated with HIV DNA, but there was no evidence for an association with proviral DNA and CD4 T cell exhaustion.

Participants making a CD4 T cell ELISPot response to HIV Gag had significantly lower HIV DNA levels (p<0.05; Mann Whitney), with weaker evidence for an association with CD8 T cell immunity (P=0.03 and 0.05 for responses to 0 vs 3 Gag overlapping peptides for ‘total’ and ‘integrated’ DNA, respectively).

In univariable analyses of untreated individuals at PHI, both ‘total’ and ‘integrated’ DNA were significant predictors of clinical progression. In multivariable analyses, ‘total’ DNA remained strongly associated with trial outcome (HR 3.6; P=0.002), whereas integrated DNA and plasma viral load did not.

In patients receiving 48 weeks of suppressive ART, total HIV DNA at time of stopping therapy was predictive of trial end-point (HR 3.6; p=0.01) and time to plasma viral load rebound (HR 2.5; P=0.007).

**Conclusions:** This is the first comprehensive analysis of the HIV reservoir in the context of HIV-specific immunity, inflammation and clinical progression in a large randomized clinical trial in PHI. The data confirm the close relationship between immunity, inflammation and the reservoir in PHI, and show that reservoir size is a key predictor not only of progression but also of virological control on stopping ART.

404 Next Generation Plasma HIV-1 RNA Single Copy Assays

Anthony R. Cillo1, David Vagratian2, Margaret Bedison2, Elizabeth Anderson2, Mary Kearney1, Elizabeth Fyne2, Dianna Koontz2, John Coffin1, Michael Piatak1, John Mellors2

1School of Medicine, University of Pittsburgh, Pittsburgh, PA, United States, 2University of Pittsburgh, Pittsburgh, PA, United States

**Background:** A qPCR assay with single copy sensitivity targeting HIV-1 gag (gSCA) has been widely used to quantify plasma HIV-1 RNA below the limit of clinical assays. However, with current extraction methods, gSCA incompletely recovers a spiked internal standard (avian sarcoma virus, RCAS), and fails to efficiently amplify 15-30% of HIV-1 subtype B sequences due to mismatches in the gag primer/probe binding sites. To address these limitations, we developed a next generation SCA with improved extraction efficiency and primers/probes targeting highly conserved sequences in integrase (iSCA). We also explored assayng larger plasma volumes to increase iSCA sensitivity (Mega-iSCA).

**Methodology:** Primers/probe for qPCR were designed to target a highly conserved 3’ region of HIV-1 integrate away from drug-resistance sites. Recovery of the spiked internal standard RCAS was used to optimize the extraction method. Paired plasma samples from 30 consecutive donors (25 with suppressed viremia for >2 years; 5 with viremia >50 copies/mL) were obtained to compare iSCA versus gSCA. For viremic patients, HIV-1 RNA recovery <10% of Roche TaqMan v2.0 was scored as inefficient amplification. Between iSCA and gSCA, >3-fold differences in HIV-1 RNA were considered significant. Large plasma volumes (up to 34 mL) were assayed by Mega-iSCA to achieve a theoretical limit of detection (LOD) of 0.05 copies/mL.

**Results:** Testing of the plasma panel from 30 donors revealed that the median recovery of the internal standard was 1.5 times higher with iSCA compared to gSCA (p<0.001, signed rank test). In samples from the 5 patients with viremia >50 copies/mL, gSCA efficiently amplified 2 of 5 whereas iSCA efficiently amplified all 5 compared with TaqMan (p=0.01, exact binomial test). In samples from all 30 patients, 12 of 30 had >3-fold recovery of HIV-1 RNA with iSCA versus gSCA, while 3 of 30 had >3-fold recovery with gSCA (p<0.001, exact binomial test). Using gSCA, 11 of 30 samples were undetectable compared with 7 of 30 samples using iSCA (p=0.088, exact binomial test). Large volume plasma samples from 7 patients with HIV-1 RNA <50 copies/mL were assayed by Mega-iSCA (4 of 7 were negative by standard iSCA). Mega-iSCA detected HIV-1 RNA in 6 of 7 samples including 3 of 4 negative by standard iSCA.

**Conclusions:** An optimized extraction method and primers/probe targeting highly conserved sequences in the 3’ region of pol improved viral RNA recovery and decreased false negatives. Assaying larger plasma volumes by Mega-iSCA lowered the theoretical limit of detection for HIV-1 RNA to 0.05 copies/mL and improved sensitivity for persistent viremia. iSCA and Mega-iSCA should be useful for measuring the impact of therapeutic interventions and in differentiating between “functional” and “sterilizing” cures of HIV-1.
Assessment and Quantification of Cell Associate Unspliced HIV-1 RNA Using RT-ddPCR

Zixin Hu, Carlos Becerril, Nina H. Lin, Jonathan Li, Andrea Heisey, Atie M. Tsibris, Daniel R. Kuritzkes
Division of Infectious Diseases, Brigham and Women’s Hospital and Harvard Medical School, Boston, MA, United States

Background: Quantification of cell-associated HIV-1 RNA is critical to understanding how HIV-1 latency is established and maintained in a reservoir of infected cells during antiretroviral therapy. Droplet digital polymerase chain reaction (ddPCR) can detect and precisely quantify the target nucleic acids without the need for a calibration curve. Previous studies demonstrated that ddPCR is generally comparable to traditional qPCR methods for the quantification of both total HIV-1 DNA and episomal 2-LTR circles. In this study, we developed a reverse transcriptase (RT) ddPCR assay and compared to quantitative reverse transcriptase-PCR(qRT-PCR) for detection and quantification of unspliced cell-associated HIV-1 RNA in both HIV-infected cell lines spiked with HIV-infected cells and clinical samples from patients on antiretroviral therapy (ART) with very low-level viremia.

Methodology: To evaluate the ability of RT-ddPCR to measure cell-associated HIV-1 RNA, serially diluted (2.5 to 10^8 copies/10 ul RNA input) in vitro transcribed HIV-1 RNA was quantified by RT-ddPCR and qRT-PCR. We analyzed ≥5 replicates of the 100-copy standard to assess the accuracy and reproducibility of RT-ddPCR. Levels of cell-associated HIV-1 RNA were determined in clinical samples from patients on suppressive ART, and from MT2 cells spiked with the latently-infected cell line ACH2.

Results: RT-ddPCR accurately quantified HIV-1 RNA transcripts; the dynamic range was 10 to 10^5 copies per 10 ul RNA input (R2 > 0.99), which represented similar sensitivity as qRT-PCR. The 100-copy input showed that the percentage of positive droplets most closely correlated with the expected copy number. For samples with input RNA of 10^3 to 10^5 copies, the copies detected was ~10% lower than expected; for samples with <100 copies of input RNA the calculated copy number was slightly higher than expected (mean 1.9-fold difference). Linearity decreased significantly when greater than 10^5 copies due to saturation of positive droplets formation. HIV-1 RNA measured by RT-ddPCR and qRT-PCR in samples from co-culture of serially diluted reactivated ACH2 cells together with MT2 cells lines were highly correlated (R2=0.9668). HIV-1 RNA was detected by RT-ddPCR in 14/20 samples (range, 4-284 copies/million PBMC) and by qRT-PCR in 13/20 samples (range, 6-479 copies/million PBMC), respectively.

Conclusions: The RT-ddPCR assay detected and accurately quantified cell-associated HIV-1 RNA with a dynamic range down to 10 copies per reaction. RT-ddPCR demonstrated similar accuracy and sensitivity compared to qRT-PCR in the measurement of cell-associated HIV-1 RNA in both cell-lines spiked with HIV-infected cells and in patient samples. RT-ddPCR is a promising tool for the quantification of HIV-1 cell-associated RNA.

Measuring HIV Latency Over Time: Reservoir Stability and Assessing Interventions

Nancie M. Archin1, Amanda M. Crooks1, Rosalie Bateson1, Anna B. Cope2, Noelle P. Dahl1, Joseph J. Eron1, Cynthia L. Gay1, JoAnn D. Kuruc1, David M. Margolis1, 3, Ronald J. Bosch4
1Department of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 2Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 3Department of Microbiology & Immunology, Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 4Department of Biostatistics, Harvard School of Public Health, Boston, MA, United States

Background: The quantitative viral outgrowth assay (QVOA) is the gold standard for measuring the latent reservoir of HIV infection, yielding precise measurement of the reservoir of resting CD4+ T cell infection (RCI). But variability of RCI over time on ART, relevant to assess potential effects of anti-latency interventions, has not been fully described. We report an analysis of 160 QVOAs.

Methodology: HIV+ male participants, stably HIV RNA <50 c/ml on ART, donated resting CD4+ T cells via leukapheresis. Acute HIV infection (AHI) patients (plasma HIV RNA detected and HIV Western blot negative) were identified via the North Carolina STAT program, and initiated ART within 45 days of the estimated diagnosis (range 7-45, median 19 days); one patient initiating ART 6 months after infection (early infection) was also studied. Once HIV RNA was <50 copies/ml for 6 months, leukapheresis was performed and RCI quantitated. QVOA was performed using 30-225 million resting CD4+ T cells in 24-96 replicate cultures in limiting-dilution format. RCI was similarly measured for patients initiating ART during chronic infection (CHI). Random effects regression evaluated RCI decay and estimated sources of variability, restricting to RCI measures obtained ≥12 months after ART.

Results: 17 AHI and 20 CHI were studied (ages 19-66 years), including a total of 160 independent QVOA measures (median 4 per patient at median 3 months intervals; median 1.2 years RCI follow-up). Median ART duration at first RCI was 21 months AHI, 78 months CHI. CD4 count at first RCI was 744 cells AHI, 584 CHI. RCI significantly declined over time (p<0.001) with estimated mean (95% CI) half-life = 3.6 (2.3-8.1) years. There was no evidence of more rapid decay for AHI vs. CHI (p=0.99) after ≥12 months of ART. From the model, the estimated SD for the change in log10 RCI for a patient = 0.38, implying that a >2.5 fold RCI decrease over 2 months would have likelihood 0.16 (16%) under stable ART. A >6 fold RCI decrease would have likelihood 0.023 (2.3%). Empirically evaluating the 123 pairs of consecutive RCI measures, 81 (66%) had <2 fold increase or decrease; 21 (17%) had >2.5 fold decreases and 3 (2.4%) had >6 fold decreases.

Conclusions: Consistent with prior studies, RCI decayed with a half-life of 3.6 years (43 months). Based on using large numbers of cells obtained via leukapheresis, RCI was reliably estimated with longitudinal measurements generally showing <2 fold variation from the previous measure. RCI decreases >6 fold were rare on stable suppressive ART, suggesting a potential threshold to identify effects of anti-latency therapeutics on RCI.
What and Where Is the Reservoir?

407LB The Role of HIV Integration Sites in Extensive Clonal Expansion of Infected Cells in Patients
Frank Maldarelli1, Xiaolin Wu1, Mary Kearney1, Ling Su2, Wei Shao2, Shawn Hill1, Francesco Simonetti1, Jon Spindler1, John Coffin1, Stephen H. Hughes1
1HIV Drug Resistance Program, NIH, Frederick, MD, United States, 2Leidos, Inc, Frederick, MD, United States, 3ISP/Advanced Biomedical Computing Center, Leidos, Inc, Frederick, MD, United States, 4Department of Molecular Biology and Microbiology, Tufts University School of Medicine, Boston, MA, United States

Background: Despite successful suppression of HIV by combination antiretroviral therapy (cART), infected cells persist for many years in patients. Long-term control of viremia by cART reveals clonal viral genomes in the blood of most patients, implying clonal expansion of some HIV infected cells. The mechanisms driving clonal expansion are unknown, but are central to HIV persistence. To address this issue, we determined the distribution of proviral integration sites in 5 patients on successful cART using a specific and highly sensitive amplification strategy that yields large numbers of virus-host junctions, identifies their exact location, and measures the relative degree of clonal expansion.

Methodology: DNA was prepared from PBMCs from 5 patients, randomly sheared, and linker-mediated PCR was used to selectively amplify both the 5’ and 3’-LTR integration site junctions, whose sequences, as well as those of the sheared breakpoints in the host DNA, were determined by illumina paired-end sequencing. Clonal expansion of infected cells was demonstrated by the presence of DNA fragments with exactly the same integration site and different host DNA breakpoints.

Results: Analysis of integration site libraries comprising >2000 independent integration events revealed clonal expansion of HIV infected cells in all patients studied. In one patient, about half of the infected PBMCs were derived from a single infected cell. Infected clones persisted in patients for at least 11 years. Integrations in the same orientation in a specific intron of two different genes (MKL2 and BACH2), were seen in independent clones from more than one patient. In one patient, we detected 669 unique sites, of which 14 were in different expanded clones derived from independent integration events in a single 3.5 kb intron of MKL2, and 12 were in a single intron of BACH2. These data show that the expression of these genes must have been affected by these integrations in ways that made a critical contribution to the clonal expansion and/or persistence of the infected cells. Both these genes have been linked to the control of cell growth and human cancers. Other genes associated with cell growth (e.g., PAK2, STATS5, and CYTH1) in which HIV DNA integration may have contributed to clonal expansion and persistence, were also identified in more than one patient.

Conclusions: Extensive expansion of HIV infected cell clones, some persisting for >11 years, demonstrates that the reservoir of infected cells in patients is maintained, at least in part, by cell division. Although the HIV provirus may serve as a passive marker of clonal expansion, our results show that the HIV integration site can also make an important contribution to the expansion and/or persistence of infected cell clones.

408 Identification of a New Th17 Subset That Contributes To HIV-1 Persistence in ART-Treated Subjects
Vanessa S. Wacleche1, 2 Annie Gosselin1, Patricia Monteiro1, Aurélie Cleret-Buhot1, 2, Sandrine DaFonesca1, 2, Mohammad Ali Jenabian1, Jean-Pierre Routy1, Petronela Ancuta1, 3
1CR-CHUM, Montreal, QC, Canada, 2Université de Montréal, Montreal, QC, Canada, 3McGill University Health Centre, Montreal, QC, Canada

Background: Th17 cells play a critical role in mucosal immunity against bacterial pathogens. Th17 cells are depleted from the gut-associated lymphoid tissues of HIV-infected individuals and their functional restoration under antiretroviral therapy (ART) is only partial. We previously reported that Th17 cells exhibiting a CXCR3-CCR4+CCR6+ phenotype (CCR4+CCR6+ Th17) are permissive to HIV infection and their frequency is diminished in chronically HIV-infected subjects receiving viral-suppressive ART (CI on ART). We recently identified a new subset of Th17 cells with a CXCR3-CCR4-CCR6+ phenotype (DN CCR6+) that expressed RORC mRNA. Here, we investigated the relative contribution of DNNCR6+ and CCR4+CCR6+Th17 cells to immunity and HIV pathogenesis.

Methodology: Leukapheresis from CI on ART subjects (n=24; CD4 counts >318 cells/μL, plasma viral load <50 HIV-RNA copies/ml) and uninfected controls (n=21) were available for these studies. Highly pure memory Th17 subsets were sorted by flow cytometry and stimulated via CD3/CD28. Lineage-specific cytokines and transcription factors were quantified by ELISA and RT-PCR, respectively. Antigenic-specificity and polarization profiles were determined by flow cytometry analysis of T-cell proliferation (CFSE dilution assay) and cytokine expression (intracellular staining), respectively. HIV replication and integration was measured by ELISA and real-time PCR, respectively.

Results: Similar to CCR4+CCR6+ Th17, DN CCR6+ cells produced IL-17A, and proliferated in response to Candida albicans (a Th17 antigen) but not Cytomegalovirus (a Th1 antigen). The stability of the Th17 profile in DN CCR6+ and CCR4+CCR6+ Th17 cells was proved upon long-term culture under Th17 or Th1 conditions in vitro. DN CCR6+ distinguished from CCR4+CCR6+ Th17 cells in their ability to produce high levels of IL-17F and low levels of IFN-γ. As opposed to CCR4+CCR6+ Th17, the frequency of the DN CCR6+ cells was preserved in HIV-infected subjects. Finally, DN CCR6+ cells were permissive to R5 HIV infection in vitro and levels of integrated HIV-DNA were similarly high in DNNCR6+ and CCR4+CCR6+ Th17 cells isolated from CI on ART HIV-infected subjects.

Conclusions: Our results reveal the existence of a new previously uncharacterized subset of Th17 cells with a DNNCR6+ phenotype. Because they are preserved in frequency during HIV infection and carry integrated HIV-DNA in CI on ART subjects, DN CCR6+ Th17 cells may particularly contribute to HIV persistence under ART. These studies provide a new understanding of Th17 heterogeneity in the context of HIV pathogenesis. Mechanisms by which HIV-infected DN CCR6+ Th17 cells avoid killing by CD8+ T-cells and/or NK cells thus persisting in HIV-infected subjects remain to be investigated.
Identifying Defective and Identical Viral Genomes in HIV Reservoirs During Effective HIV Therapy

Sussanne von Stockenstrom1, Lina Odevall1, Elizabeth Sinclair1, Rui A. Raposo1, Douglas F. Nixon1,4, Hiroyu Hatano2, Peter Hunt3, Peter Bacchetti5, Steven G. Deeks6, Frederick M. Hecht6, Sarah Palmer1,4

1Department of Microbiology, Tumor and Cell Biology, Karolinska Institutet, Stockholm, Sweden; 2Department of Medicine, University of California San Francisco, San Francisco, CA, United States; 3Division of Experimental Medicine, University of California San Francisco, San Francisco, CA, United States; 4Department of Microbiology, Immunology and Tropical Medicine, The George Washington University, Washington, DC, United States; 5Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA, United States; 6Centre for Virus Research, Westmead Millennium Institute for Medical Research and University of Sydney, Sydney, Australia

Background: A thorough understanding of the distribution of replication-competent virus will be needed to design future HIV eradication therapies. We studied the distribution of replication defective viral genomes in memory T cell subsets in blood and lymph nodes of long-term treated subjects. We also examined the distribution of clonal sequences in order to define the role of homeostatic proliferation as a cause of persistence.

Methodology: Using single-proviral sequencing we isolated intracellular HIV-1 genomes derived from defined subsets of CD4+ T cells (naïve, central (CM), transitional (TM), and effector (EM)-memory) from peripheral blood and lymph node tissue. Samples were collected from 8 subjects on suppressive therapy (4-12 years): 5 ini the study during early infection and 3 during chronic infection. G-to-A hypermutants were identified using the Hypermut program within the Los Alamos HIV Database. Levels of APOBEC 3F and 3G (A3F and A3G) were measured in T cells (CM, TM and EM) from blood and lymph node tissue using a gene expression sybr green method. Additional defective viral genomes were determined by stop codons or large deletions. Identical sequences were identified by phylogenetic analysis.

Results: The percent of cells infected with hypermutants was estimated to be 31% lower in CM cells than it was in EM cells (p=0.54), and it was estimated to be 35% higher in TM cells than in EM cells (p=0.51) but the percent of cells infected with other defective viral genomes tended to be higher for EM than CM (38-fold, p=0.0024) and TM (11-fold, p=0.0028). In both blood and lymph node tissue the gene expression of A3G and 3F was highest in CM cells (EM>T>M). The estimated proportion of viral genomes that were hypermutants in subjects treated during early versus chronic infection was similar for all three cell types (<1.6-fold differences), but in EM cells the proportion of all viruses that had other defects was estimated to be >20-fold higher for chronic than early (p=0.018). Phylogenetic analyses showed expansions of identical HIV-1 sequences in all subjects treated during chronic infection; these expansions were predominantly found in EM T cells.

Conclusions: We found that the estimated proportion of HIV genomes during long-term ART that were hypermutants was similar in cells from subjects treated during early and chronic infection, suggesting that these genomes are established soon after infection. We also found >10-fold higher rates of non-hypermutant defective viral genomes in EM cells than either CM or TM cells in blood. These defective genomes and identical HIV-1 sequences predominated in EM T cells of specific subjects, suggesting that they were maintained by clonal expansion of T cells as they differentiated into more terminal cell populations.

Healthy HIV-Infected Subjects Harbor HIV in Alveolar Macrophages, Which Can Impair Lung Function

Sushma K. Cribbs1, David M. Guidot1, Angela M. Caliendo2, Lou Ann Brown3, Jeffrey Lennox4

1Pulmonary/Critical Care Medicine, Emory University, Atlanta, GA, United States; 2Brown University, Providence, RI, United States; 3Pediatrics, Emory University, Atlanta, GA, United States; 4Infectious Diseases, Emory University, Atlanta, GA, United States

Background: Alveolar macrophages are specialized innate immune cells that reside in the alveolus, a site with different concentrations of some medications compared to the blood compartment. Alveolar macrophages can be infected by HIV-1 as they express CXCR4 and CCR5, and HIV reverse transcriptase has been detected in alveolar macrophages from humans. The half-life of alveolar macrophages is significantly longer than that of an activated lymphocyte (months/years versus hours/days). However, reports quantifying the burden of HIV in alveolar macrophages are conflicting, and it is unclear what impact the infection has on alveolar macrophage function. We hypothesize that the alveolar macrophage is an important reservoir for HIV, contributing to cell-cell spread of the virus within the lung and exhibiting abnormal function, which contributes to the increase risk of severe lung infections.

Methodology: We conducted a pilot study on healthy HIV-infected subjects who did not have major medical co-morbidities or smoke cigarettes. All subjects underwent bronchoscopy and bronchoalveolar lavage with 180mL of normal saline. Alveolar macrophages were isolated and HIV-1 RNA was quantified in the cells using the Abbott RealTime HIV-1 Assay (Abbott Molecular Inc. Des Plaines, IL), an in vitro reverse transcription-polymerase chain reaction assay. Proviral DNA was quantitatively measured using a modified version of the above-mentioned HIV-1 RNA viral load assay. To measure phagocytic function, alveolar macrophages were isolated and incubated for 1 hour with FITC-labeled S. aureus in a 10:1 ratio. FITC-labeled bacteria containing cells were measured by flow cytometry. Phagocytic index was calculated as follows: (% positive cells x mean channel fluorescence)/100.

Results: We enrolled 22 otherwise healthy HIV-infected subjects (median CD4 count= 409/μL, 82% with undetectable plasma viral load). HIV-1 proviral DNA and/or quantitative RNA were detected in 82% of the alveolar macrophages; 78% of this group had an undetectable plasma viral load and 94% were on anti-retroviral therapy. HIV-1 RNA levels ranged from 48 to 2305 copies/mL. Further, HIV-infected subjects with proviral DNA present had decreased alveolar macrophage phagocytosis of FITC-labeled S. aureus compared to subjects without proviral DNA present [16.6 (IQR 45.2) vs. 33.1 (IQR12.2-172.1)].

Conclusions: Alveolar macrophages harbor HIV even in otherwise healthy subjects with undetectable plasma viral loads, representing a potential reservoir for the virus. In addition, HIV viral replication within the macrophage may impair phagocytosis and other immune functions in the lung, leading to an increased risk for lung infection.
**411 Quantitative and Phylogenetic Analyses of Persistent HIV in Blood and GALT During Long-Term cART**

Francesco R. Simonetti1, Shawn Hill2, Shao Wei3, Robert Gorelick4, Michael Piatak5, Mark Voellinger6, Stephen Wank7, Gabriella Diaz2, Joe Kovacs2, Frank Maldarelli1

1HIV Drug Resistance Program, National Cancer Institute, Frederick, MD, United States, 2Advanced Biomedical Computing Center SAIC-Frederick, Frederick National Laboratories for Cancer Research, Frederick, MD, United States, 3AIDS and Cancer Virus Program, Frederick National Laboratories for Cancer Research, Frederick, MD, United States, 4National Institute of Digestive and Kidney Diseases, Digestive Disease Branch, National Institutes of Health, Bethesda, MD, United States, 5Critical Care Medicine Department, Clinical Center, National Institutes of Health, Bethesda, MD, United States

**Background:** HIV infection results in profound effects on gut associated lymphoid tissue (GALT), and combination antiretroviral therapy (cART) only partly reverses HIV-induced destruction. The role of GALT in ongoing HIV persistence remains uncertain. Previous studies have analyzed HIV sequences obtained from pools of multiple pinch biopsies; the degree of sampling variation in individual biopsies is unknown, but pooling may introduce significant bias in estimating the size and structure of HIV populations. To quantify the distribution of infected cells, and determine the phylogeny of local HIV populations within the gut mucosa, we analyzed endoscopy-derived material as individual or small pools of biopsies. We compared viral populations in gut to those obtained from contemporaneous and pre-therapy plasma and peripheral blood mononuclear cells (PBMC).

**Methodology:** Eight HIV infected patients on suppressive cART for 2-10 years were enrolled. Plasma and PBMC were obtained prior to cART and at time of colonoscopy; small jaws forceps were used to obtain random biopsies from colon and from ileum, when possible. Biopsies were collected as individual snips or pooled in groups of 2-8 snips. Ultrasensitive qPCR assay targeting gag was performed to quantify HIV-DNA and RNA copy number; total cell number was determined by qPCR of CCR5 gene. Single genome sequences (SGS) from plasma RNA, PBMC-derived DNA, and gut-derived DNA and RNA were obtained and underwent phylogenetic analysis (MEGA).

**Results:** We obtained 6-12 individual pinch from colon in each subject and 6-12 pinches from ileum in 5/8 patients. Single copy detection revealed HIV DNA in all pinch biopsies, with a relatively stable DNA copy number (mean 291 cps/10^6 cells, range 83-741, overall patients). In contrast, HIV RNA levels were more variable and ranged <12-220 HIV RNA cps/10^6 cells. No evidence of compartmentalization was detected, either between gut and peripheral blood or among pinch. Clones of identical sequences were detected in plasma and PBMC and were also present in gut DNA and RNA. Clonal HIV sequences were identified from multiple snips, suggesting that clones were not anatomically restricted. No genetic divergence from pre-therapy HIV was detected in gut or blood-derived HIV, even after >10y of cART.

**Conclusions:** HIV proviruses are extensively and uniformly distributed throughout the GALT with an estimated 100 million infected cells present in colonic mucosa despite prolonged cART; HIV RNA production varied considerably among pinch. Clonally expanded populations present in gut mucosa were not anatomically restricted, and were not divergent from pre-therapy HIV. Detection of the same identical sequences in gut derived DNA, RNA, and plasma suggests that GALT can be a source of persistent viremia on ART.

---

**412 The Immune Checkpoint Blockers PD-1, LAG-3 and TIGIT Are Associated With HIV Persistence During ART**

Remi Fromentin1, Sandrina Da Fonseca1, Wendy Bakeman1, Gabriela Khoury2, Elizabeth Sinclair1, Frederick Hecht1, Steven G. Deeks2, Sharon R. Lewin2, 4, Rafick P. Sekaly1, Nicolas Chomont1

1HIV Drug Resistance Program, National Cancer Institute, Frederick, MD, United States, 2Infectious Diseases, Alfred Hospital and Monash University, Melbourne, Australia, 3Medicine, UCSF, San Francisco, CA, United States, 4Centre for Biomedical Research, Burnet Institute, Melbourne, Australia

**Background:** The persistence of HIV in a small pool of long-lived latently infected resting CD4 T cells is a major barrier to viral eradication. Interfering with the immunological mechanisms that maintain latency in these cells may lead to novel therapeutic strategies to cure HIV infection. Several immune checkpoint blockers (ICBs) have been shown to actively reduce T cell activation, proliferation and cytokine production in CD4 T cells. We hypothesized that expression of one or several of these ICBs contribute to HIV persistence by continuously and actively promoting HIV latency in infected CD4 T cells.

**Methodology:** Expression of PD-1, CTLA-4, Lag-3, TIGIT, TIM-3, BTLA, 2B4 and CD160 were measured by flow cytometry on PBMCs from 48 subjects on ART for >3 years with HIV viral load inferior to 50 cop./mL and a CD4 count > 350 cells/μL. The frequencies of CD4 T cells harboring integrated HIV DNA, total HIV DNA, 2-LTR circles and cell associated unspliced (CA-US) HIV RNA were determined by qPCR. Integrated HIV DNA was also measured in sorted memory CD4 T cell subsets expressing some of these ICBs. More specifically, the impact of PD-1 engagement on HIV latency was evaluated in CD4 T cells isolated from virally suppressed subjects using beads coated with anti-CD3, anti-CD28, PD-L1 or the appropriate control.

**Results:** Absolute CD4 T cell counts were negatively correlated with the expression of PD-1, Lag-3 and TIGIT in CD4 T cells (r = -0.53 p<0.0001, r = -0.51 p=0.0002, r = -0.40 p=0.005, respectively). Interestingly, the frequency of CD4 T cells harboring integrated HIV DNA was positively correlated with the expression of these markers (r = 0.29 p = 0.06, r = 0.31 p=0.04 and r = 0.46 p=0.002, for PD-1, Lag-3 and TIGIT, respectively). With the exception of TIGIT with 2-LTR circles (r = 0.39 p=0.009), no statistically significant associations were found between these markers and total HIV DNA, 2-LTR circles or CA-US HIV RNA. Memory CD4 T cells expressing high levels of PD-1 or Lag-3 were enriched for HIV integrated DNA when compared to their negative counterparts. Engagement of PD-1 with its ligand PD-L1 inhibited viral production induced by TCR stimulation in latently infected cells (mean=94.8 % of inhibition), suggesting a functional role for this receptor in the maintenance of HIV latency.

**Conclusions:** We identified PD-1, Lag-3 and TIGIT as markers associated with incomplete CD4 T cell restoration and HIV persistence during ART. Our data further demonstrate that PD-1 and Lag-3 identify cells carrying integrated HIV DNA in virally suppressed subjects. Collectively, these data suggest that a limited number of specific ICBs may actively promote HIV persistence during ART. Interfering with PD-1 and Lag-3 signaling may disrupt HIV latency and paves the way for the development of novel curative strategies.
413 Distinct Patterns of TLR-Mediated HIV Reactivation in Latently-Infected Microglia vs Monocytes

David Alvarez, Yoelvis Garcia-Mesa, Biswajit Das, Curtis Dobrowolski, Stephanie Milne, Roxana Rojas, Jonathan Karn
Molecular Biology and Microbiology, Case Western Reserve University, Cleveland, OH, United States

Background: Toll-like receptors (TLRs) recognize molecules derived from microbes and play a key role in mediating innate immune responses. Multiple TLRs are typically expressed in cells of the monocytic lineage, including microglia. Microglial cells constitute the major reservoir for HIV infections in the brain, where inflammatory conditions in the central nervous system (CNS) are believed to induce HIV-associated neurocognitive disorders (HAND).

Methodology: Microglial cells pseudo-infection and culture, treatment with TLR agonists and cytokines, flow cytometry, and fluorescence microscopy.

Results: Using HIV-latently infected microglial cell lines, we investigated whether TLR stimulation can induce HIV transcription. Treatment with a panel of TLR ligands, including Mycobacterium tuberculosis (Mtbo)-derived molecules, we found that, unlike in monocytic cells, reactivation of HIV by TLR ligands was significantly restricted in microglia. Flagellin (TLR5 agonist) and, to a lesser extent, lipopolysaccharide (LPS; TLR4 agonist) were able to reactivate HIV in hTERT-immortalized glial (hT-Hμglia/HIV) and in SV40-immortalized (CHME-5/HIV) human fetal microglial cells. In the presence of IL-1β, a cytokine over-expressed in HAND patients, Pam3CSK4 (TLR1/2 agonist) can also reactivate HIV. By contrast, agonists for TLR1, 2, 4, 5, 6, or 8 (but not for TLR3, 7, or 9), potently reactivated HIV in THP-1/HIV cells and, to a lesser extent, in U937/HIV and SC/HIV monocytes in an NF-κB-dependent manner. Mtb-derived molecules PIM6 and LprG, which are potent TLR2 agonists, reactivated HIV in THP-1/HIV, but not in U937/HIV or SC/HIV cells which, unlike THP-1/HIV, showed no significant expression of TLR2.

Conclusions: We conclude that TLRs signaling probably plays a minor role in activating HIV replication in the CNS that can be potentiated in the context of brain inflammation, but can potentially drive replication in peripheral monocytic cells.

414 CXCR3 and CCR5 Expression Are Associated With 2LTR Circles in Patients On Antiretroviral Therapy

Gabriela Khoury1, Jenny Anderson2, Rémi Fromentin3, Nicolas Chomont4, Elizabeth Sinclair5, Wendy Hartogensis6, Peter Bacchetti7, Frederick M. Hecht6, Steven G. Deeks3, Sharon R. Lewin3, 4
1Infectious Diseases, Monash University & Alfred Hospital, Melbourne, Victoria, Australia, 2Burnet Institute, Melbourne, Victoria, Australia, 3Vaccine and Gene Therapy Institute of Florida, Port St Lucie, FL, United States, 4Medicine, University of California San Francisco, San Francisco, CA, United States, 5University of California San Francisco, San Francisco, CA, United States

Background: Identifying a subset of T-cells that are enriched for HIV infection in patients on suppressive antiretroviral therapy (ART) will be critical to developing new curative strategies. This study aimed to assess how the expression of inflammatory (CCR5, CXCR3, CCR6, CXCR5) and homeostatic (CCR7) chemokine receptors (CKR) and their ligands correlate with the size of the latent reservoir in patients receiving suppressive ART.

Methodology: 48 subjects on ART for >3 years with HIV viral load <50 copies/ml were recruited in San Francisco. Using flow cytometry, we quantified the expression of the CKR CCR5, CXCR3, CCR6, CXCR5 and CCR7 on CD4+ T-cells. The corresponding ligands for these chemokine receptors were quantified in plasma (Luminex). Total, integrated and 2LTR circle HIV DNA and cell associated unspliced (CA-US) HIV RNA was quantified in CD4+ T-cells. Spearman correlations and negative binomial regression models were performed to test associations between markers of virus persistence and CKR expression on CD4+ T-cells adjusting for current and nadir CD4 T-cell counts.

Results: Subjects were predominantly male (96%) with a median CD4= 684 (IQR=533-858) cells/μl. There were statistically significant negative correlations between current CD4 count and expression of the inflammatory CCR5 (r=-0.50, p<0.001), CCR6 (r=-0.42, p<0.01) and CXCR3 (r=-0.57, p<0.0001) and a positive correlation with the homeostatic CCR7 (r=0.59, p<0.0001). There was a statistically significant negative correlation between integrated HIV DNA and current CD4 (r=-0.52, p=0.0001) but not nadir CD4. CCR5 was the only CKR that substantially correlated positively with integrated HIV DNA (r=0.29, p=0.045) but this largely disappeared when controlled for current or nadir CD4 count in a negative binomial regression model. 2-LTR circles were negatively correlated with nadir CD4 (r=-0.45, p=0.002) but not current CD4. In a negative binomial regression model, 2LTR circles were positively correlated with CXCR3 expression (p=0.001) and CCR5 expression (p=0.032) and both remained statistically significant after adjusting for nadir or current CD4 count. There was no significant relationship between total HIV DNA, CA-US RNA and CKR expression. There was no statistically significant relationship between virus persistence and any of the chemokines measured in plasma, except for a positive correlation between 2LTR circles and the ligand for CCR7, CCL21 (r=0.30, p=0.045).

Conclusions: The association of 2LTR circles with nadir CD4 and CXCR3 and CCR5 expression on CD4 T-cells raises the possibility of ongoing replication in cells that express these specific inflammatory CKR, such as effector memory T-cells, particularly in individuals who initiate ART at lower CD4 counts.

415 CD4+ and CD8+ T Cell Activation Are Strongly Associated With HIV-1 DNA in Resting CD4+ T Cells

Leslie Cockerham1, Janet D. Siliciano2, Elizabeth Sinclair3, Una O'Doherty4, Sarah Palmer4, Steven A. Yukl5, Matt C. Strain3, Robert F. Siliciano6, Douglas R. Richman2, Steven G. Deeks7
1HIV/AIDS Division, University of California - San Francisco, San Francisco, CA, United States, 2Department of Medicine, Johns Hopkins University, Baltimore, MD, United States, 3Division of Experimental Medicine, University of California - San Francisco, San Francisco, CA, United States, 4Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, PA, United States, 5The University of Sydney, Sydney, Australia, 6San Francisco VA Medical Center, San Francisco, CA, United States, 7University of California - San Diego, San Diego, CA, United States, 8Johns Hopkins University, Baltimore, MD, United States

Background: The association between the host immune environment and the size and between multiple measurements of the reservoir (Eriksson et al, PLoS Path 2013). Here, we explored the association between HIV persistence as defined by these assays and the level of T cell activation and function.

Methodology: We performed multiple simultaneous measurements of HIV persistence and analyzed their association with immune function and T cell activation in 30 antiretroviral-treated adults: 10 who started therapy during acute infection and 20 who initiated treatment during chronic infection. All individuals were on a suppressive antiretroviral regimen for at least 36 months and had > 350 CD4 cells/ul. The following assays were performed on
patient samples: viral outgrowth, digital droplet PCR (ddPCR) for HIV-1 DNA and 2-LTR circles in PBMCs and resting CD4+ T cells, Alu PCR for integrated HIV-1, and a single copy assay for plasma virus. Flow cytometry was performed to measure frequencies of activated and HIV-specific T cells in blood. Spearman rank correlation coefficients were calculated.

**Results:** The most consistent host response associated with HIV persistence was frequency of “activated” (%HLA-DR+ // CD38+) CD4+ and CD8+ T cells. CD4+HLA-DR+ T cells were strongly associated with frequency of resting CD4+ cells containing total HIV-1 DNA as measured by ddPCR (ρ = 0.65, P = 0.006). There were similar associations with activated CD8+ T cells (%CD4+HLA-DR+CD38+; ρ = 0.51, P = 0.04). This association was strongest with activation in central memory and effector memory CD4+ T cells. Other markers of activation including PD-1 and the co-expression of all markers (CD38+HLA-DR+CCR5+PD1+) on CD8+ T cells were also correlated with HIV DNA in resting CD4+ T cells (PD-1: ρ = 0.37, P = 0.04). HIV-specific CD4+ T cells expressing TNF-α and IL-21 were positively correlated with total HIV DNA in resting cells by ddPCR (TNF-α: ρ = 0.54, P = 0.046, IL-21: ρ = 0.72, P = 0.004). Similar non-significant trends were observed with HIV specific CD4+ T cells expressing IL-2 and IFN-γ. Non-significant negative associations were observed between HIV-specific CD4+ T cells and the frequency of latently infected cells by co-culture.

**Conclusions:** The frequency of CD4+ and CD8+ T cells expressing activation markers and the frequency of HIV-specific CD4+ cells are directly associated with the frequency of resting cells harboring HIV DNA. Although defining causation in this study is not possible, one possibility is that T cell activation drives persistence, perhaps as a consequence of cell proliferation. This may have implications for reactivation strategies, as reversal of latency, in the absence of effective killing and complete suppression of viral replication, could lead to an increase in reservoir size.

**416 Targeting SIV Reservoirs via Autologous Hematopoietic Stem Cell Transplant in Rhesus Macaques**

Maud Mavigner1, Benjamin Watkins1,2, Benton O. Lawson1, Ann Chahroudi1,2, Leslie S. Kean1,2, Guido Silvestri1

1Yerkes National Primate Research Center, Emory University, Atlanta, GA, United States, 2Department of Pediatrics, Emory University, Atlanta, GA, United States, 3Emory Transplant Center, Emory University, Atlanta, GA, United States

**Background:** Despite many advances in the field of AIDS research, a treatment that eradicates the infection remains elusive. A key obstacle to the development of a cure for HIV is an incomplete understanding of the cellular and anatomical nature of viral reservoirs in the setting of successful ART. To address this gap in our understanding, we developed a model of autologous hematopoietic stem cell transplantation (aHSCT) in SIV-infected, ART-treated rhesus macaques (RM) to interrogate the origin of the SIV reservoir.

**Methodology:** This pilot study included three SIV-infected RM who received aHSCT and three SIV-infected control RM. The transplant procedure involved pre-infection G-CSF mobilization of CD34+ HSC followed by leukapheresis and cryopreservation of collected cells. All RM were then infected i.v. with RT-SHIV. Four weeks post-infection a potent ART regimen including PMPA, FTC, Efavirenz and Raltegravir was initiated. The three experimental RM received total body irradiation (TBI) followed by infusion of the HSC collected pre-infection. ART was interrupted 40 to 80 days post-transplant. Immunophenotyping of PBMC and measurements of plasma SIV RNA and PBMC SIV DNA levels were collected throughout the study. Multiple tissues described as potential virus reservoirs were collected at necropsy for virologic analyses.

**Results:** As expected, the ART regimen reduced plasma SIV RNA levels to below 100 copies/ml in all six SIV-infected RM. TBI was myeloablative as measured by circulating platelet, white blood cell, and lymphocyte counts and, following aHSCT, engraftment was successful in all three transplanted RM. A rapid viral rebound was observed in plasma in the non-transplanted control RM as early as one week post-ART interruption. Despite TBI and transplant with pre-infection HSC, plasma SIV RNA rebound was also observed post-ART interruption in two out of three transplanted RM. In contrast, no SIV RNA was detected in the plasma of one transplanted RM at week two post-ART interruption. Furthermore, no SIV DNA was detected in the PBMC of this transplanted animal. However, despite the lack of viral rebound in plasma in this transplanted animal, further analysis of various tissue sites revealed the presence of SIV DNA in spleen and lymph nodes, but not in the gastrointestinal tract.

**Conclusions:** To the best of our knowledge, this model of SIV/aHSCT has never been attempted before. SIV infection followed by aHSCT in virally-suppressed ART-treated RM allows for critical assessment of hematopoietic and non-hematopoietic HIV/SIV reservoirs. Early evidence from this study suggests that non-hematopoietic reservoirs contribute to HIV/SIV persistence. The results of this work may be translated into novel HIV cure strategies.

**417 Dynamics of HSPC Repopulation in Non-Human Primates Revealed by a Decade-Long Clonal Tracking**

Sanggu Kim1, Namshin Kim1, Angela Presson1, Dong Sung An1, Robert E. Donahue1, Irvin S. Y. Chen1

1University of California, Los Angeles, Los Angeles, CA, United States, 2Korean Bioinformatics Center, Daejeon, Republic of Korea, 3National Heart, Lung and Blood Institute, Bethesda, MD, United States

**Background:** Hematopoietic stem cell and progenitor cell (HSPC)-based genetic therapy to treat HIV or other previously incurable diseases is becoming increasingly realistic. To date, however, our understanding of the regenerative potentials of primate HSPCs lags far behind the level desired for current and future uses of these cells for therapeutic purposes.

**Methodology:** We report detailed behavior patterns of repopulating HSPCs in four rhesus macaques transplanted for up to 12 years with autologous CD34+ HSPCs engineered with control lentivirus vectors expressing a fluorescence marker (EGFP) or therapeutic vectors expressing shRNA against the HIV-1 co-receptor, C-C chemokine receptor type 5 (CCR5-shRNA). All animals showed normal hematopoietic recovery and maintained stable EGFP
marking in all tested blood lineages. In order to study in vivo HSPC behaviors at the single cell level, vector marked clones in serially collected blood were analyzed by large-scale vector integration site (VIS) sequencing and bioinformatics analysis of genomic VIS sequences.

Results: Our long-term clonal tracking study revealed novel mechanistic insights into complex polyclonal hematopoietic reconstitution in primates, not seen in traditional population-based studies. Analysis revealed thousands of HSPC clones successfully engrafted and expanded sequentially over time in each animal, clustered into groups with different kinetics of repopulation, maintaining the total marked blood cells at a relatively stable level over the years. Consistent with recent discoveries in murine HSC studies, the long-term repopulating clones were distinctively grouped into “myeloid-biased”, “lymphoid-biased”, and “balanced” subtypes based on their unique lineage output potentials. Interestingly, clones with more balanced lineage potentials, accounted for only 4 – 10% of the identified clones, yet predominated, contributing up to 25 – 71% of total repopulating cells in test animals. No notable effect of CCR5-shRNA expression upon clonal repopulation was observed.

Conclusions: This study is the first system level description of the detailed in vivo behavior patterns of primate HSPCs, providing new insights into primate repopulation and a potential frame of reference for future HSPC-based gene-therapies.

418 Impact of Systemic Cytotoxic Chemotherapy for Malignancies On HIV-1 Reservoir Persistence

Timothy J. Henrich, Emily Hanhauser, Jonathan Z. Li, Andrea Heisey, Jeremy S. Abramson, Ayad Hamdani, Philippe Armand, Ann S. LaCasce, Daniel R. Kuritzkes

1Brigham and Women’s Hospital, Harvard Medical School, Cambridge, MA, United States, 2Brigham and Women’s Hospital, Cambridge, MA, United States, 3Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, 4Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, United States, 5Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, United States

Background: The effects of cytotoxic chemotherapeutic agents on viral reservoir size are not well understood. Therefore, we studied the longitudinal effect of combination chemotherapy for hematologic malignancies and single-agent chemotherapy for Kaposi Sarcoma (KS) on HIV-1 reservoir size.

Methodology: HIV-infected individuals with a diagnosis of malignancy, including hematologic malignancies, KS and Multicentric Castleman’s Disease (MCD) requiring systemic chemotherapy were enrolled. Large volume peripheral blood collections were performed at time points before, during, and post-chemotherapy. Flow cytometric characterizations of T lymphocyte subsets were performed and viral DNA and RNA were extracted and quantified from purified CD4+ T cells using sensitive real-time PCR assays. Residual plasma viremia was also quantified using a single-copy RNA assay.

Results: We obtained 28 samples from 15 patients (KS/MCD = 4, Hodgkin = 2, non-Hodgkin lymphoma = 9). In an analysis of all participants, a non-significant decrease in CD4+ T cell-associated HIV-1 DNA was observed between the pre- or earliest on chemotherapy time-points and the first post-chemotherapy time-point (median 576 and 228 copies/10^6 CD4+ T cells, P=0.26 from paired analysis; see Figure). A non-significant decrease in DNA was also observed in a subset of patients on stable antiretroviral therapy with all viral loads <1000 copies/mL (N=13, median 523 and 213 copies/10^6 CD4+ cells, P=0.39). No significant changes in CD4+ T cell-associated RNA were observed, and the frequency and amplitude of residual viremia were similar across time-points. One patient with both angioblast T-cell lymphoma and B-cell lymphoma had undetectable HIV-1 DNA and RNA from purified CD4+ T cells and no detectable viremia by Cobas Taqman PCR viral load assay after 8 cycles of salvage chemotherapy with brentuximab and high-dose methotrexate. The patient died from recurrent CNS disease pending allogeneic stem cell transplantation.

Conclusions: Peripheral blood HIV-1 reservoirs persist after cytotoxic chemotherapy, although one patient had undetectable cell-associated DNA and RNA on salvage chemotherapy for T cell lymphoma. These findings suggest that cytotoxic chemotherapy may have an impact on viral reservoir size, but this effect may vary depending on specific oncologic, chemotherapeutic and viral disease factors. Further investigation of immune function, inflammation and activation in this cohort is warranted.

419 Modeling Functional Cure of HIV in Nonhuman Primates Using Gene-Modified Hematopoietic Stem Cells

Hans-Peter Kiernan, Christopher W. Peterson, Patrick M. Younan, Shiu-Lok Hu, Patricia Polacino, Michael Holmes, Philip Gregory, Jianbin Wang

Transplantation Biology, Fred Hutchinson Cancer Research Center, Seattle, WA, United States, 2University of Washington, Seattle, WA, United States, 3Sangamo Biosciences, Richmond, CA, United States

Background: Following hematopoietic stem cell (HSC) transplantation and withdrawal of combination antiretroviral therapy (cART), three previously HIV+ patients remain free of measurable replication-competent virus. These results suggest that HSC transplantation represents a promising strategy to induce a functional cure. To better understand the mechanism of HSC-driven HIV control, and apply this therapy to a greater number of patients, we are developing a model of cART-suppressed HIV infection in the pigtailed macaque applicable to both gene therapy- and allogeneic transplant-based cure strategies. Following transplantation of HIV-resistant, autologous cells into conditioned animals, we are evaluating the extent to which protected cell progeny impedes infection by SIV/HIV (SHIV) chimeric virus in vivo.

Methodology: Animals are challenged with SHIV virus containing an HIV envelope, after which a 3-drug cART regimen is initiated. Autologous HSCs are engineered to resist infection through transgenic expression of the anti-fusion peptide mC46. Engraftment, persistence, and SHIV response of these autologous stem cells, and stem cell-derived lymphoid and myeloid cells, are measured in vivo.
Results: SHIV infection in the pigtailed macaque model results in sustained viremia with consequent reduction in CD4+ T cells. Moreover, administration of three-drug cART to SHIV-infected animals leads to rapid and durable suppression of plasma viremia to <30 copies/mL plasma - suggesting that this model recapitulates key features of HIV infection and treatment in humans. Transplant of mC46-modified HSCs followed by SHIV infection drives positive selection for mC46-modified cell progeny in peripheral blood and secondary lymphoid tissues, resulting in increased CD4+ T-cell counts and an enhanced SHIV-specific immune response against the challenge virus.

Conclusions: Our pigtailed macaque model of HIV infection and cART represents a promising platform for modeling functional cure strategies, including allogeneic transplant. Here we show that expression of mC46 (one strategy for inhibiting HIV infection) protects T-cells from SHIV-dependent depletion by enabling host immune cells to antagonize spreading infection. These data demonstrate that our pigtailed macaque model is suitable for the pre-clinical evaluation of other functional cure strategies including the knockout of CCR5 by zinc finger nucleases. In addition, this model enables the evaluation of novel therapeutic approaches in the clinically relevant context of cART controlled SHIV infection - a setting of particular importance to approaches aimed at addressing the viral reservoir.

Background: There is limited information on decay of persistent viremia in patients on long-term ART with HIV-1 RNA <50 copies (c)/mL. We evaluated patterns of persistent viremia and evidence for ongoing decay in a large cohort of patients on suppressive ART for >10 years.

Methodology: Plasma samples obtained at approximately 4, 7, 10, and 12 years after ART initiation from subjects enrolled in the ACTG ALLRT cohort (A5001) were tested for HIV-1 RNA with a single copy assay (SCA) targeting HIV-1 gag. Selected subjects were ART-naïve at baseline, had HIV-1 RNA <50 c/mL from week 32 of ART forward, with ≥ 3 mL of stored plasma available at each time point. SCA amplification efficiency, compared to the Roche HIV Monitor assay v1.5, was determined from pre-therapy plasma for subjects with SCA < 1 c/mL. The limit of detection of the SCA for 3 mL of plasma was 0.6 c/mL. A decline in the likelihood of HIV-1 RNA being ≥ 1 c/mL during follow-up was assessed using a repeated measures logistic regression model.

Results: Plasma SCA was performed on 4 to 6 samples each from 64 subjects: two measurements were obtained at 4 years of ART (Weeks 192 and 208); and 2-4 measurements were obtained at 2-3 year intervals thereafter. Median duration from ART initiation to last SCA was 11.2 years. Subjects were categorized into 3 groups based on the results at year 4: Persistent viremia (+/+ defined as SCA ≥ 1c/mL at both Weeks 192 and 208; N=17), Intermittent viremia (+/- or -/+; SCA ≥ 1c/mL at 1 of the 2 time points; N=25), or Undetectable (-/-; <1 c/mL at both; N=22). Subject characteristics by group are shown in the Table. Pre-ART HIV-1 RNA levels differed across groups (p=0.027, Kruskal-Wallis) with highest levels in the Persistent viremia group (Table). Subjects with Persistent viremia during year 4 generally had viremia ≥ 1c/mL at years 7 and 10 (65% and 56%, respectively); by contrast, subjects with Undetectable viremia during year 4 rarely had viremia ≥ 1c/mL at years 7 and 10 (14% and 9%, respectively) (Table). In the subset with SCA ≥ 1c/mL at Week 192 (N=27 with total of 111 subsequent SCA measurements) the median SCA at Years 4, 7, and 10 was 1.9, 1.5, and 1.3 c/mL, respectively, and there was no evidence (p=0.55) of a decline in the probability of SCA ≥ 1c/mL over time.

Conclusions: The level of residual viremia measured at ~4 years of suppressive ART remained stable for up to 11 years post-ART follow up with no clear evidence for further decay. The mechanisms responsible for stable persistence of different levels of viremia on ART require investigation.
**421LB Comparison of Combination ART Regimens for Viral Suppression in SIV-Infected Rhesus Macaques**

G. Del Prete¹, R. Gelsinzius², J. Hesselgesser², B. Li¹, J. Hattersley¹, B. Lu², J. Zheng³, J. Smalley², M. Piatak, Jr.¹, J. D. Lifson¹

¹AIDS and Cancer Virus Program, Leidos Biomedical Research, Inc., Frederick, MD, United States, ²Gilead Sciences, Inc., Foster City, CA, United States, ³Laboratory Animal Sciences Program, Leidos Biomedical Research, Inc., Frederick, MD, United States

**Background:** Nonhuman primate (NHP) models of human HIV infection, including the most commonly used model involving SIV-infected Indian rhesus macaques, represent an important component of the HIV cure research agenda. Feasible, sustainable combination antiretroviral treatment (cART) regimens to achieve clinically relevant levels of suppression (SIV plasma RNA < 30 copies/ml) are an essential element to enable use of such models in evaluation of experimental HIV cure strategies, but developing such regimens has proven challenging.

**Methodology:** We compared two different cART regimens (Tenofovir disoproxyl fumarate/Emtricitabine/Dolutegravir; TDF/FTC/DTG vs. Tenofovir disoproxyl fumarate/Emtricitabine/Dolutegravir/Darunavir; TDF/FTC/DTG/DRV), both given as a single, daily, co-formulated subcutaneous injection, in SIVmac239 infected Indian rhesus macaques (n = 3 each), with treatment initiated 2 weeks after intravenous infection. After the initial 4 weeks of treatment, all animals received the TDF/FTC/DTG regimen. We evaluated drug levels, plasma viremia, cell associated SIV RNA and DNA and immune activation.

**Results:** Both regimens were well tolerated based on clinical and laboratory (CBC and serum chemistry panel) evaluations. Starting from pretreatment plasma viral load of ~3-4 X 10^7 SIV RNA copies/ml, both regimens provided comparable 4 log declines in plasma viremia over the first 4 weeks of treatment, associated with decreased evidence of SIV infection related immune activation, based on HLA-DR and Ki67 expression. Continued treatment of all animals with TDF/FTC/DTG after the initial 4 weeks of cART produced continued decreases in plasma viremia, to < 30 copies/ml in all animals, by 22 weeks post-infection (20 weeks on cART).

**Conclusions:** Both regimens resulted in prompt, effective suppression of SIVmac239 replication, as reflected by plasma viremia. There was no clear advantage associated with the addition of Darunavir to the regimen during the initial four weeks of treatment, and with continued treatment with TDF/FTC/DTG all animals were suppressed to < 30 copies/ml. TDF/FTC/DTG is an effective suppressive regimen in SIV-infected Indian rhesus macaques, and should facilitate NHP model studies of interventions targeting residual virus in cART suppressed individuals. TDF/FTC/DTG activity was comparable to that of the same regimen using Tenofovir (TFV) instead of TDF evaluated in prior studies; use of TDF instead of TFV in the combination should help minimize potential renal toxicities with long term administration.

---

**422 Impact of RAL/MVC Intensification With or Without HIV-rAd5 Vaccination On HIV DNA: ERAMUNE 02 Study**

Chad Achenbach¹, Steven Deeks², Timothy Wilkin³, Baiba Berzins¹, Joseph Casazza⁴, Sidonie Lambert⁵, Christine Kallama³-⁶, Brigitte Autran⁵, ⁶, Robert Murphy⁷, the ERAMUNE 02 Study Group

¹Northwestern University, Chicago, IL, United States, ²University of California San Francisco, San Francisco, CA, United States, ³Cornell University, New York, NY, United States, ⁴National Institutes of Health/Vaccine Research Center, Bethesda, MD, United States, ⁵Hôpital Pité-Salpêtrière, Paris, France, ⁶Université Pierre et Marie Curie (UPMC), Paris, France

**Background:** HIV eradication may require synergistic interventions that purge latent reservoirs and increase the HIV-specific cellular immune response. DNA prime followed by recombinant adenovirus 5 boost vaccination (HIV-rAd5) has been shown to induce strong CD8+ cytotoxic T lymphocytes responses in HIV-infected and uninfected individuals.

**Methodology:** Randomized, controlled, non-comparative clinical trial of ART intensification (raltegravir and maraviroc (RAL/MVC)) with or without HIV-rAd5. We included patients having: ≥3 years of HIV-1 RNA <500 copies/mL, HIV-1 RNA <40 copies/mL ≥one year, current CD4+ cell count ≥350/mm³, HIV-1 DNA between 10 and 1,000 copies/10^6 PBMCs and serum Ad5 neutralizing antibody titer ≤ 250. After a lead-in of RAL/MVC intensification for 8 weeks, patients were randomized (1:1) to continue intensification with HIV-rAd5 vaccination [DNA prime at W8-W12-W16 and rAd5 boost at W32 (RAL/MVC/HIV-rAd5 arm)] or continue intensification alone (RAL/MVC arm) for 48 weeks. The primary end-point was >0.5 log10 decrease in HIV-1 DNA at 56 weeks. Secondary end-points included changes in rectal tissue HIV-1 DNA, immunologic changes in peripheral blood, and safety.

**Results:** We enrolled 28 patients (14 in each arm) on suppressive ART with the following median baseline characteristics: 636 CD4+ cells/mm³, 672 CD8+ cells/mm³, 170 HIV-1 DNA copies/10⁶ PBMCs, 13 years on ART, and 2.6 years with HIV-1 RNA <40 copies/mL. At week 56, one patient in the RAL/MVC arm reached the primary endpoint with a 0.55 log₁₀ decrease in HIV-1 DNA from 156 (W0) to 44 (W56) DNA copies/10⁶ PBMCs. Mean PBMC and rectal tissue cell-associated HIV-1 DNA levels did not significantly change after RAL/MVC intensification with or without HIV-rAd5 injections (see table). Peripheral blood CD4+ and CD8+ cell counts did not significantly change from baseline to W56 in either arm (see table). RAL/MVC intensification and HIV-rAd5 vaccination were well tolerated and there were no serious SAEs related to study treatment.

**Conclusions:** RAL/MVC intensification with HIV-rAd5 vaccination did not reduce the total HIV DNA reservoir in either peripheral blood or rectal tissue. RAL/MVC intensification alone decreased the HIV-1 reservoir by over 0.5 log DNA copies/10⁶ PBMCs in one patient.
Impact of Three Different ART Regimens On the GALT: A Randomized Clinical Trial

Sergio Serrano-Villar1, Tala Sainz2, Anthony Albanese1, Tammy Yotter3, Paolo Troia-Cancio4, Steve Deeks5, Elizabeth Sinclair6, Darin Lartimore7, Vera Go8, David Asmuth9
1Infectious Diseases Department, Hospital General Ramon y Cajal, Madrid, Spain; 2Molecular Immune-Biology Laboratory, Hospital General Universitario Gregorio Marañon, Madrid, Spain; 3University of California Davis Medical Center, Sacramento, CA, United States; 4UCSF, San Francisco, CA, United States; 5UCDMC and VANCHCS, Sacramento, CA, United States

Background: Acute HIV infection leads to depletion of the gastrointestinal-associated lymphoid tissue (GALT), driving bacterial translocation, chronic T-cell activation and disease progression. The aim of this study was to evaluate whether ART initiation regimen might determine mucosal recovery, and whether intensification with a fourth drug might achieve better immune reconstitution.

Methodology: In this clinical trial, 33 ART naïve HIV-infected subjects were randomized to three different ART strategies: EFV, MRV or MRV+RAL, each in combination with TDF/FTC. Peripheral blood (PB), rectal biopsies, and duodenal biopsies were obtained at baseline and after 9 months of ART. Tissue was digested into single-cell suspensions for flow cytometry of lymphocyte subsets and activation (HLADR+CD38+) phenotypes.

Results: Twenty-six HIV+ subjects completed the follow-up: 8 on the EFV arm, 10 on the MRV arm and 8 on the MVC+RAL arm. Median age was 37 years [25-42] without significant differences between groups. In the EFV, MVC and MVC+RAL arms, median preART CD4 counts were 322, 440 and 453 cell/mm3, (between-group comparisons, P=ns.). All patients achieved complete HIV suppression. Absolute CD4 T-cell counts significantly increased on PB after 9 months of ART by 151 cell/μl [43-386], 239 [128-288] and 281 [120-342], as well as all the %CD4 (delta: 14%, 11%, 17%). The %CD8 significantly declined (delta: 13%, 9%, 17%). However, all between-group comparisons were non-significant, even after adjustment for baseline CD4 T-cell counts. In EFV, MVC and MVC+RAL arms, ART resulted in substantial increases in %CD4 in the GALT, both in duodenal (delta: 10%, 10%, 19%) and rectal mucosa (delta: 21%, 18%, 13%), as well as declines in %CD8 (duodenal delta: -11%, -12%, -20%, and rectal: -21%, -18%, -22%). In the adjusted analysis, the extent of preART %CD4 depletion in duodenal mucosa determined CD4 T-cell recovery, both in PB and GALT (Beta 0.48, P=0.02 and Beta 0.42, P=0.042, respectively), but no effect of treatment was identified.

Peripheral %HLADR+CD38+ CD8+ T-cells significantly decreased in blood at 9 months post ART, the largest decrease was observed in the MVC+RAL arm (delta: -25%, -24%, -34%, between-group comparisons, P=ns). Changes in CD8+ T-cell activation in the GALT were modest compared to those observed in blood (duodenum, delta: -6%, -9%, -29%; colon, delta: -19%, -5%, -5% (between-group comparisons, P=ns)).

Conclusions: Results of this pilot clinical trial in HIV-infected subjects suggest that CD4 depletion at GALT at ART initiation determine CD4 recovery. Overall, initiation with a quadruple ART regimen showed better immunological restoration in blood and GALT, but the differences remained non-significant and larger studies will be needed to confirm this hypothesis.

HIV Reservoir Changes in Resting CD4 Subsets in the IL7 Plus ART Intensification Eramune-01 Study

Manuela Pogliaghi1, 2, Sidonie Lambert1, 4, Lambert Assoumou3, Rima Zoomb1, Laura Papagno1, 6, Francois Lecardonnel2, Vincent Calvez3, 4, Christine Katlama5, 7, Brigitte Autran3, The Eramune-01 Study Group

Background: The ERAMUNE01 trial showed that a year of MVC+RAL intensification alone or with 3 IL7 injections in treated chronic HIV+ patients did not decrease cell HIV DNA. IL7 induced a strong transient CD4 T cells increase affecting mainly the CM subset. To further understand the effects of IL7 we evaluated distribution and characteristics of viral reservoir among the distinct resting CD4 T cell subsets.

Methodology: We sorted resting CD25-69-DR-CD4+ N, CM, TM and EM T subsets at D0 and W56 from RAL+MVC and RAL+MVC+IL7 arms (6+6 pts). Unspliced HIV RNA transcripts from total CD4 were detected using qPCR (GAG gene). RNA released in supernatants being normalized for HIV DNA content 3) Transcriptome was analysed using the human genome wide microarray Platform 4) Reservoir, using nonparametric tests; 2) HIV inducibility was tested in vitro with or without IL7 or antiCD3+CD28+IL2+IL7 D0 stimulation, amounts of HIV RNA released in supernatants being normalized for HIV DNA content 3) Transcriptome was analysed using the human genome wide microarray Platform 4)

Results: At D0 reservoir distribution did not significantly differ among sorted resting CD4 subsets despite a higher contribution of CM than EM in RAL+MVC+IL7 (p 0.01). At W56 cell HIV DNA did not change in any RAL+MVC subset. At W56 RAL+MVC+IL7 CM reservoir did not significantly increase though CM delta raw (HIV DNA/10*6 CM p 0.02), absolute values (HIV DNA/CM/mL p 0.008) and fold changes (W56-D0/D0 p 0.04) from baseline increased more than in RAL+MVC. Instead RAL+MVC+IL7 TM HIV DNA raw and absolute values increased at W56 (p 0.03) and when compared to RAL+MVC (p 0.01). Thus the RAL+MVC+IL7 reservoir became skewed towards an increase in TM compared to N as raw values (p 0.02) and an increase in CM and TM compared to EM as absolute values (p 0.04). IL7 alone induced HIV production in vitro from both arms (5/8 CM and 7/8 TM tested subsets); antiCD3+CD28+IL2+IL7 stimulation induced HIV in all tested sorted sample (N, CM, TM, EM at D0 and CM at W56). Ex vivo analysis of HIV RNA transcripts showed no IL7 effect 2 to 46 weeks after IL7 infusions. Similarly no transcriptome changes were observed in any resting CD4 T cell subsets between D0 and W56 in both arms.

Conclusions: A year long strategy combining a cycle of IL7 injections plus MVC+RAL intensification did not show major changes in HIV reservoir among resting CD4 T subsets (except an increase in TM cells with intermediate lifespan) despite IL7 ability to trigger HIV production in vitro, to expand "early" (CM) memory and to decrease more differentiated and senescent T cells. A year after IL7 cycle, distribution of reservoir remains however skewed towards TM with a reduced contribution of short-lived EM cells, suggesting those changes do not simply reflect homeostatic proliferation effects of IL7.
425LB Pre-ART HIV-1 RNA as well as On-Treatment CD8 Count and CD4/CD8 Ratio Predict Residual Viremia On ART
Sharon A. Riddler1, Evagina Aga1, Ronald Bosch1, Barbara Bastow1, Margaret Bedison1, David Vagratian1, Joseph J. Eron1, Rajesh Gandhi5, John W. Mellors1, for the ACTG A5276s Protocol Team
1Medicine/Infectious Diseases, University of Pittsburgh, Pittsburgh, PA, United States, 2Statistical & Data Analysis Center, Harvard School of Public Health, Boston, MA, United States, 3Social & Scientific Systems, Inc., Silver Spring, MD, United States, 4Medicine/Infectious Diseases, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, 5Medicine/Infectious Diseases, Massachusetts General Hospital, Boston, MA, United States

Background: Prior studies have identified pre-ART plasma HIV-1 RNA level as the strongest predictor of residual viremia on ART but analyses have had limited power to identify other associations. We examined pre-therapy and on-treatment predictors of residual viremia in a large, well-characterized ACTG cohort.

Methodology: Plasma samples obtained 192 and 208 weeks after ART initiation from subjects enrolled in the ACTG ALLRT long-term follow-up study (A5001) were tested with a single copy assay (SCA) targeting HIV-1 gag. Selected subjects were ART-naive, had HIV-1 RNA <50 c/ml from week 32 of ART forward, and had a 3 ml stored plasma available for each SCA. The limit of detection of the SCA was 0.4-1 c/ml. SCA amplification efficiency compared to the Roche HIV Monitor assay v1.5 was determined by testing pre-therapy plasma for subjects with SCA <1 c/ml at both on-treatment time points. Subjects with samples showing <10% amplification efficiency were excluded. Logistic regression for repeated measures (using GEE) was used to estimate odds ratios (ORs) for each predictor.

Results: A total of 334 subjects had SCA results at weeks 192 and 208 of suppressive ART. The majority of subjects (82%) were male with pre-ART median age of 40 years, median CD4 cell count 248 cells/mm³, and HIV-1 RNA 4.7 log₁₀ c/ml. Initial ART regimens were NNRTI + NRTIs (61%), PI + NRTIs (28%), and other (11%). The median CD4 cell count after 4 years of ART (average of weeks 192 and 208) was 588 cells/mm³. The SCA values (n=668) ranged from <0.4 to 41.4 (median <1; IQR <1, 2.5); among those values ≥1 c/ml (n=296), the median was 2.8 (IQR 1.7, 5.2). In univariate analysis, the likelihood of residual viremia ≥1 c/ml was predicted by higher pre-ART HIV-1 RNA (OR 1.79 per 1 log₁₀ [95% CI 1.32, 2.42], p<0.001), higher on-treatment CD8 cell count (OR 1.07 per 100 cells/mm³ [95% CI 1.02, 1.12], p=0.008), and lower on-treatment CD4/CD8 ratio (OR 0.72 per 0.5 [95% CI 0.58, 0.90], p=0.004). The type of initial ART regimen, sex, race/ethnicity, injection drug use, age, pre-ART or on-treatment CD4 cell count, and pre-ART or on-treatment CD4/CD8 ratio were not associated with residual viremia (all p>0.05). After adjusting for pre-ART HIV-1 RNA, the average CD8 cell count and CD4/CD8 ratio at weeks 192 and 208 remained significant predictors of residual viremia (p=0.014 and 0.031, respectively).

Conclusions: In this large, cross-sectional study, the level of residual viremia was predicted by higher pre-ART HIV-1 RNA as well as by higher on-treatment CD8 cell count and lower on-treatment CD4/CD8 ratio. Whether residual viremia is a cause or consequence of these immunologic differences requires further investigation, including interventions that affect residual viremia or T cell reconstitution.

Immunology for Cure

426 Eradication of HIV-1 Reservoirs With Antibody Mediated Killing
Zelda Euler1, Seav H. Ly1, Matthew Hurton1, Athe M. N. Tsibris1, 2, Galit Alter1
1Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States, 2Division of Infectious Diseases, Brigham and Women’s Hospital, Boston, MA, United States

Background: To date, there is no effective cure for HIV-1. The ‘shock and kill’ approach aims to reactivate the reservoir and target its clearance via immune or therapeutic mechanisms. Beyond T cells, purging the reservoir after reactivation with HIV-specific antibodies that recruit the cytotoxic and antiviral activity of the innate immune system has not been assessed. It has been shown that functional antibodies have a protective effect in HIV-disease progression and were induced in the RV144 vaccine trial. Finding epitopes targeted by functional antibodies on reactivated latent cells could lead to the design of new therapeutic approaches to eradicate HIV reservoirs.

Methodology: Latently HIV-1 infected cell lines (ACH2, J89GFP and U1), were treated for 24 hours with PHA or the histone deacetylase inhibitors (HDACi) vorinostat, panobinostat, or romidepsin and incubated with monoclonal antibodies (mAbs) to Env (n=30) for the detection of various epitopes on reactivated cells. Intracellular p24 or GFP and extracellular Env were detected with flow cytometry. An antibody dependent cellular phagocytosis (ADCP) assay was performed on reactivated ACH2 (Panobinostat). A monocyteic cell line, THP-1, were stained by cell trace blue, while ACH2 cells were stained by CFSE and cultured for 4 hours in the presence of mAbs. Percentage phagocytosis was calculated as double positive cells over CFSE alone. Here we show that HDACi-reactivated latently infected cell lines robustly expressed Env on the cell surface. More critically, a clear hierarchy was observed among tested mAbs in their ability to recognize reactivated cells, and recruit innate effector activities that can promote efficient killing or eradication of the reservoir. These findings provide a critical footprint for epitopes that a therapeutic vaccine or passive transfer antibodies needs to target that could lead to the rapid elimination of the reservoir, providing a path to a functional cure.
427LB Maraviroc Reverts Latent HIV-1 in ART Suppressed Patients Through NFkB Without Viral Load Increase

Nadia Madrid-Elena1, Beatriz Hernández-Novoa1, Beatriz Sastre Turnión1, Sergio Serrano-Villar2, Ajantha Solomon3, Carolina Gutiérrez1, Javier Zamora3, Laura Garcia-Bermejo3, Sharon R. Lewin4, Santiago Moreno5

1Infectious Diseases, Hospital Ramón y Cajal, Madrid, Spain, 2Burnet Institute, Melbourne, Australia, 3Hospital Ramón y Cajal, Madrid, Spain, 4Infectious Diseases, Monash University, Burnet Institute and Alfred Hospital, Melbourne, Australia

**Background:** CCR5 intracellular signaling pathways leading to NF-κB, NFAT and AP-1 activation, could promote HIV-1 transcription in resting CD4+ T cells. In previous experiments, we have shown that maraviroc could activate NF-κB and specific target genes in resting CD4+ T cells from viremic and ART suppressed HIV-1 infected patients. The aim of the current work was to explore HIV-1 transcription, the implicated mechanisms and the effect on HIV-1 viral load.

**Methodology:** We conducted a clinical trial of 10 days of maraviroc (MVC) intensification in 10 HIV-1 infected adults on suppressive ART (MARAVITRANS; Eudra CT: 2012-003215-66). Blood was collected at baseline, after 1, 3 and 10 days on MVC and 18 days after MVC withdrawal. NF-κB, NFAT and AP-1 activation in resting CD4+ T cells were detected by an ELISA-based kit (Actif Motif). NF-κB activity was estimated measuring target genes’ expression by real-time PCR. Cell-associated HIV-1 unspliced RNA (usRNA) was quantified in resting CD4+ T cells by real-time PCR. Viral load was measured by kPCR (Siemens). Significant changes in NF-κB activation respect to usRNA levels were determined using Multilevel Mixed Model analyses.

**Results:** All patients completed full MVC dosing and follow up. We observed in 8/10 patients an increase in NFκB activation at day 10 and persisted after drug withdrawal in some patients (day 28), including two patients with D/M tropic virus. Upregulation of at least one NF-κB target gene was observed in cases where NF-κB activation was detected. However, we did not detect activation of NFAT or AP-1 in any patient. The mean log usRNA copies per million resting CD4+ T cells increased across the study (0.3, 0.6, 0.8 and 1.3), but was only significant at day 28 relative to baseline (p=0.014). In the 8 patients in which the presence of MVC was associated with an increase in NF-κB activation, an increase in usRNA was detected in resting CD4+ T cells. Finally, an association between NF-κB activation and usRNA levels could be shown by a Multilevel Mixed Model analysis, which revealed statistical significance at day 10 with respect to baseline (p=0.04) in patients with NF-κB activation (Fig.1). All patients had undetectable plasma viral load at all timepoints, with no blips observed.

**Conclusions:** Taken together, our data suggest that MVC can activate NF-κB and the subsequent reversion of latent HIV-1 in resting CD4+ T cells from ART suppressed HIV-1-infected patients, without viral load increase.

428 Regulatory B cells Attenuate Anti-HIV CTL Responses After Reactivation of Latent Reservoirs

Basile Siewe1, Jennillee Wallace1, Sonya Rygielski1, Jack T. Stapleton2, Jeffrey Martin3, Steven G. Deeks4, Alan Landay1

1Rush University Medical Center, Chicago, IL, United States, 2Iowa City Veterans Affairs Medical Center and the University of Iowa, Iowa City, IA, United States, 3Rush University Medical Center, San Francisco, CA, United States, 4HIV/AIDS Division, San Francisco General Hospital, University of California, San Francisco, CA, United States

**Background:** To achieve HIV eradication, the mechanisms underlying impaired cytotoxic T lymphocyte function (CTL) during antiretroviral therapy (ART) must be elucidated. In HIV-peptides stimulated samples, IL-10hi programmed-death ligand-1 (PD-L1)hi regulatory B cells (Bregs, CD19+CD24hiCD38hi) attenuate anti-HIV CTL activity. Here we investigate immunoregulatory Breg function in the clinically relevant setting of HIV viral reactivation in vitro using the FDA-approved HDAC inhibitor, suberoylanilide hydroxamic acid (SAHA).

**Methodology:** We assessed endogenous Breg frequency and phenotype in HIV-infected ART-treated (n=20, HIVART), viremic (n=17, HIVVIR) and uninfected (n=20, HIVNEG) subjects. In SAHA (500nM) treated VPD450 (proliferation dye)-labeled total or Breg-depleted PBMC from HIVART subjects, we evaluated the frequency of CD107a+ and HIV-specific (HIV-Dextramer) CD8+ T cells, CD4+ T cell proliferation, and frequency of p24+CD4+ T cells. We assessed HIV DNA by qRT-PCR. Cell-associated HIV-1 unspliced RNA (usRNA) was quantified in resting CD4+ T cells by real-time PCR. Viral load was measured by kPCR. In previous experiments, we have shown that maraviroc could activate NF-κB and specific target genes in resting CD4+ T cells from viremic and ART suppressed HIV-1 infected patients. The aim of the current work was to explore HIV-1 transcription, the implicated mechanisms and the effect on HIV-1 viral load.

**Results:** Compared to HIVNEG subjects Breg-frequency was slightly lower in HIVVIR (p<0.06) and significantly lower in HIVART (p=0.01) subjects. However, Bregs from HIVVIR subjects expressed highest levels of IL-10 (HIVNEG <p<0.0001, HIVVIR p<0.0001). Bregs from HIVART also expressed more IL-10 than those from HIVNEG (p<0.01). Breg PD-L1 levels were comparable in HIVNEG and HIVVIR but about 30% higher in Bregs from HIVART subjects. After SAHA treatment, Breg-depletion led to higher frequencies of CD107a+ (p=0.06) and HIV-specific (HIVgagSL9+, p=0.09) CD8+ T cells. In Breg-depleted samples, enhanced CTL phenotype was associated with 218% more HIV in culture supernatant, a reduction in p24+CD4+ T cells (p=0.02) and
integrated HIV DNA (p = 0.02). In co-cultures, Bregs significantly inhibited CD4+ T cell proliferation (p = 0.03) compared to a non-Breg B-cell subset, and this was partially reversed after antibody blockade of IL-10 receptor and/or PD-1.

**Conclusions:** Here we present novel data suggesting that during eradication interventions, Bregs attenuate effective CTL responses hindering the clearance of infected cells, hence these cells may represent a barrier to HIV eradication. Bregs via IL-10 and PD-L1 provision, likely modulate critical players required for the generation of effective anti-HIV CTL responses. Our data suggest that, during curative measures, Bregs might be an immunotherapy target to complement reactivation of HIV latent reservoirs.

**429 Evaluation of HIV-1 Reservoir Characteristics in a Therapeutic HIV-1 Gag Vaccine Trial**

Jonathan Z. Li1, Andrea Heisey1, Hayat Ahmed2, Michael M. Lederman2, Hongying Wang3, Lu Zheng3, Robert T. Schooley3, Daniel R. Kurtzkes3, the ACTG A5197 Study Team

1Brigham and Women’s Hospital, Harvard Medical School, Boston, MA, United States, 2Case Western Reserve University, Cleveland, OH, United States, 3Harvard School of Public Health, Boston, MA, United States, *University of California San Diego, La Jolla, CA, United States

**Background:** ACTG A5197 was a placebo-controlled trial of a therapeutic rAd5 HIV-1 gag vaccine in participants on suppressive antiretroviral therapy. The vaccine induced HIV-1 Gag-specific CD4+ interferon-γ-producing cells, which was correlated with lower viral rebound during an analytic treatment interruption (ATI). We investigated the effects of vaccination on HIV-1 reservoir characteristics prior to the ATI.

**Methodology:** Participants received the vaccine/placebo at study weeks 0, 4, and 26 prior to a 16-week ATI at week 38. Cell-associated HIV-1 RNA and DNA (CA-RNA and CA-DNA) and HIV-1 residual viremia (RV) by a single-copy assay were quantified at weeks 0, 8, and 38. HIV-specific CD4+ and CD8+ activity were assessed by an intracellular cytokine staining assay.

**Results:** At week 8, after two doses of the vaccine/placebo, modest differences between study arms were noted both in the levels of RV (vaccine [N=65] vs. placebo [N=30]: median 0.7 vs. 1.1 cp/mL, P=0.08) and proportions of individuals with detectable RV (37% vs. 57%, P=0.08). Participants in the vaccine arm with undetectable RV had a significantly higher frequency of both HIV-1 Gag-specific CD4+ interferon-γ-producing cells (undetectable [N=39] vs. detectable [N=24]: 277 vs. 161 cells/106 lymphocytes, P=0.03) and CD8+ interferon-γ-producing cells (undetectable [N=39] vs. detectable [N=24]: 1326 vs. 669 cells/106 lymphocytes, P=0.04). By week 38, however, no significant differences were observed in the numbers of Gag-specific CD4+ or CD8+ interferon-γ-producing cells between those with and without detectable RV in the vaccine arm. Therapeutic vaccination did not induce significant changes in CA-RNA or CA-DNA prior to ATI. At study entry, CA-RNA and CA-DNA levels were correlated with the numbers of HIV-specific CD4+ interferon-γ-producing cells (CA-RNA [N=93]: r = 0.23, P=0.03 and CA-DNA [N=93]: r = 0.28, P=0.01) and CA-RNA was associated with RV (r = 0.23, P=0.04, N=77). These associations weakened after vaccination and were not significant at weeks 8 and 38. Plasma HIV-1 RNA set point during the ATI was significantly associated with pre-ATI week 38 CA-RNA and CA-DNA (CA-RNA [N=90]: Spearman r = 0.51, P<0.01 and CA-DNA [N=93]: r = 0.47, P<0.01).

**Conclusions:** Early in the vaccination course, higher frequencies of Gag-specific CD4+ and CD8+ cells were associated with lower levels of RV, but this effect waned over time. Higher pre-ATI CA-RNA and CA-DNA levels were associated with higher viral load set point during the ATI, but were not significantly altered by the therapeutic vaccine. In this study, therapeutic HIV vaccination induced HIV-specific T cells, but more potent immune responses may be needed to reduce the latent HIV-1 reservoir.

**430LB Engineered TCR-Redirected Clearance of Gag-Positive Reservoir Cells From ART-Treated Subjects**

Hongbing Yang1, Sandrine Bussoser2, Gemma Hancock3, Rebecca Ashfield4, Annelise Vulisdon5, Tara M. Mahon6, Peter E. Molloy7, Namir Hassan2, Bent K. Jakobsen7, Lucy Dorrell1

1University of Oxford, Oxford, United Kingdom, 2Immunocore Ltd, Abingdon, Oxon, United Kingdom

**Background:** Combination ART is unable to eradicate HIV infection due to rapid establishment of a reservoir of long-lived latently infected CD4+ T cells. Immunotherapeutic strategies that target viral reservoirs are needed to achieve a functional cure. Immune-mobilising monoclonal T cell receptors (TCRs) have been used successfully to kill cancer cells without the need for ex vivo cellular manipulation. We report on the antiviral efficacy of TCRs that re-direct CD8+ T cells to kill HIV-infected CD4+ T cells (HIV ‘ImmTACs’).

**Methodology:** TCRs specific for the immunodominant HIV gag epitope, SLYNTVATL (SL9), and its common escape variants were engineered to achieve pimocinar affinity and fused to a humanised CD3-specific single chain antibody fragment (scFv) to create ImmTACs. The potency of these ImmTACs against CD4+ T cells from 10 HLA-A*0201+ patients on ART for >1 year was assessed using CD8+ T cell viral inhibition and killing assays.

**Results:** Replication of endogenous HIV in CD4+ T cells was significantly reduced by ImmTAC-mediated re-direction of ex vivo autologous CD8+ T cells at CD8+/CD4+ cell ratios of 1:1 and 1:10 (mean, SD: 72%, 14%, p = 0.008; 55%, 15%, p = 0.004 respectively) and at nanomolar ImmTAC concentrations (10-8 - 10-11 M). More profound inhibition (mean, SD: 85%, 8%, p < 0.0001) was achieved using CD8+ T cells from healthy donors, implying a persistent global functional defect in autologous CD8+ T cells from patients despite long-term ART. No significant effect on HIV replication was observed with CD8+ T cells alone or with an irrelevant TCR. ImmTAC-mediated killing was indicated by specific upregulation of caspase-3 in infected CD4+ T cells and by a lack of viral recrudescence after removal of the ImmTAC from cell cultures. Of note, ImmTACs enabled rapid and efficient killing of resting as well as activated CD8+ T cells and their potency was highly correlated with the level of intracellular HIV gag expression (r2 = 0.48, p < 0.0001). These data demonstrate that resting CD4+ T cells from patients were susceptible to immune killing. ImmTAC potency was dependent on CD8+ T cell phenotype, with effector memory (CCR7-/CD45RA- and CCR7-/CD45RA+) subsets showing the greatest antiviral efficacy.

**Conclusions:** HIV ImmTACs can re-direct CD8+ T cells to kill primary CD4+ T cells carrying diverse virus isolates, even when in the resting state. Their potency at low effector/target cell ratios and low epitope densities, coupled with the capacity to harness a large number of effector cells simultaneously, addresses major limitations in adaptive immunity to HIV. ImmTACs have the potential to accelerate clearance of HIV reservoirs.
**Cross-Clade Inhibition of HIV On Primary Cells by CXCR4 or CCR5 Fused To the C34 Peptide From gp41 HR2**

*Medicine, University of Pennsylvania, Philadelphia, PA, United States, 2Sangamo Bioscience, Inc, Richmond, CA, United States, 3Microbiology, University of Pennsylvania, Philadelphia, PA, United States*

**Background:** HIV-1 entry into CD4+ T cells requires binding to CD4 and either the CCR5(R5) or CXCR4(X4) co-receptor. Thus, strategies that disable productive co-receptor (CoR) engagement should provide potent protection from HIV infection. Previously we described a 34 amino acid peptide from the C-terminal heptad repeat-2 domain of gp41 (C34) which, when fused to the amino terminus (NT) of either R5 or X4, inhibits HIV-1 infection in transfected cells in vitro. Moreover, our initial studies suggested that C34-R5 or C34-X4 fusions provided trans-dominant resistance to infection irrespective of viral tropism (i.e., either C34-R5 or C34-X4 could inhibit entry of R5, X4 or dual-tropic isolates).

**Methodology:** Using lentiviral vectors, C34-R5 or C34-X4 fusion constructs were transduced into anti-CD3/CD28-stimulated primary human CD4 T-cells. Controls included GFP alone and C34-conjugated to CD4. Susceptibility to infection by R5, X4, or dual tropic HIV-1 from different clades was assessed by flow cytometry and reverse transcriptase activity (RT). Functionality of the transduced T-cells was determined by evaluating their expansion and intracellular cytokine levels after restimulation with PMA/ionomycin or anti-CD3/CD28 beads.

**Results:** In CD4 T-cells from multiple donors, when C34-R5 or C34-X4 were expressed, there was almost complete inhibition (>98%) of HIV-1 infection by intracellular p24 levels and RT. GFP-only and C34-CD4 expressing cells were infected at levels similar to untransduced T-cells. C34/CoR expression was >90% on Day 0 and stable during the 14 days of culture. Trans-dominant inhibition by C34-R5 or C34-X4 occurred for X4, R5 and dual-tropic primary isolates from clades B and A/E. Remarkably, when C34-CoR transduced and untransduced cells were titrated (1:4, respectively) and challenged with diverse HIV isolates, a condition that provides a more sustained exposure to HIV, selective enrichment of C34-CoR expressing cells occurred from the expected starting levels of ~25% up to 60% C34-CoR+ cells during viral replication. Lastly, PMA/ionomycin and anti-CD3/CD28 stimulation of C34-R5 and C34-X4 expressing T-cells grew normally and produced levels of intracellular IFNg, MIP-1b, TNFa, and IL-2 that were indistinguishable from untransduced cells.

**Conclusions:** Engineering primary CD4 T-cells with C34-modified chemokine coreceptors provides potent trans-dominant and heterologous resistance to diverse HIV-1 isolates. This cross-clade protection results in the survival and selective expansion of C34-CoR transduced cells. This novel method of engineering HIV-resistant, functional CD4 T-cells that can be expanded ex vivo and adoptively reinfused represents a promising and innovative approach with the potential to control HIV infection in humans.

**Cross-Clade Inhibition of HIV On Primary Cells by CXCR4 or CCR5 Fused To the C34 Peptide From gp41 HR2**

432LB Ing-B a Potential PKC Activator for HIV Eradication Is Active in SIVmac251-Infected Macaques

Amilcar Tanuri, Lucio Gama, Renato Santana, Mark Lewis, Andrea Savarino, Iart Shytaj, Janice E. Clements, Luiz F. Pianowski

1Genetics, UFRJ, Rio de Janeiro, Brazil, 2UFRJ, Rio de Janeiro, Brazil, 3Johns Hopkins School of Medicine, Baltimore, MD, United States, 4BioQual, Inc, Rockville, MD, United States, 5Istituto Superiore di Sanità, Rome, Italy, 6KyoLab, Valinhos, Brazil

**Background:** We here show the potential of a novel PKC activator, a hexanoate derivative of Ingenol (Ing-B) for purging the lentiviral reservoir in SIVmac251-infected macaques. cure. Here we present the preliminary results on a hexanoate derivative of Ingenol (Ing-B) in SIVmac251-infected macaques.

**Methodology:** In a pilot trial in two SIVmac251-infected macaques, Ing-B was administered in escalating doses (1, 2.5, 5 mg BID) for one week each, alternated with off-treatment weeks. Blood samples were collected at 0, 3, and 7 days post-treatment for analysis. In another experiment, two SIVmac251-infected macaques were treated with HAART composed by tenofovir, FTC, and raltegravir for 3 months to suppress viral load. After viral suppression, the animals were treated orally with Ing-B (0.2mg/kg BID) for 4 weeks and hematological , toxicological , immunological, and virological parameters were follow up weekly.

**Results:** In dose escalation trial in non-suppressed animals, Ing-B activated blood leukocytes and transiently increased plasma VL (up to 1 Log) in SIV-infected macaques. Accordingly, plasma viral load and activation markers decreased during the washout periods. Ing-B was less toxic and can be orally administered to animals with no apparent side effects. Env sequencing showed an important turnover of different quasispecies sequences from tissue to plasma in different time points during Ing-B doses. In the second trial on monkeys with suppressed VLs, Ing-B could activate latent virus, resulting in several viral load spikes during 4 weeks on treatment in the presence of HAART. These viremic peaks were preceded by an elevation of CD69+ lymphocytes and monocytes. After removing HAART and Ing-B, the VLs decreased to undetectable levels (<50 copies) in both monkeys and VL control has been maintained for 5 weeks so far. The preliminary results of the ELISpot analysis were in line with the VL trends, displaying anti-Gag immune responses when viral loads became detectable. However, following therapy interruption, cell-mediated responses against Gag decreased and eventually disappeared paralleling the reduction of VL to undetectable levels. Additionally, the CD4+ lymphocytes isolated from the two animals after Ing-B treatment yielded no intracellular vRNA after induction with PMA and ionomycin for 18hs, suggesting its impact on the viral reservoir.

**Conclusions:** Our data suggest that Ing-B is a viable candidate includable in drug combinations aimed at curing AIDS.
434  SAHA Dampens TCR-Mediated Reactivation of Latently Infected Cells
Pejman Mohammadi1,2, Julia di Iulio3,4, Miguel Munoz2, Niko Beerentwinkel1,2, Amalia Telenti2, Angela Ciuffi2
1Department of Biosystems Science and Engineering, ETH Zurich, Basel, Switzerland, 2Swiss Institute of Bioinformatics, Basel and Lausanne, Switzerland, 3Lausanne University Hospital and University of Lausanne, Institute of Microbiology, Lausanne, Switzerland

Background: Cell activation via T-cell receptor (TCR) stimulation represents a standard step in the analysis of primary cell models of HIV latency. Reactivation from latency using other pharmacological or immunological stimuli is generally benchmarked against the results of TCR signaling. We analyzed the molecular interaction between TCR stimulation and SAHA (a histone deacetylase inhibitor that increases viral transcription) to assess whether these two approaches were synergistic or antagonistic at the molecular level - with the goal of understanding post-transcriptional processing of viral transcripts.

Methodology: We use a CD4+ Tαβ latency model (Sahu et al. 2006, Tynig et al. 2010) that requires sorting of activated and infected cells, followed by reversion to a resting memory phenotype and maintenance of latent HIV by co-culture with H80 feeder cells. After 4 weeks of latency, cells were reactivated with anti-CD3/anti-CD28/IL-2 (TCR stimulation), SAHA, or both. Materials were collected at 8 and 24h post-stimulation for viral reporter analysis by FACS and for RNA-seq analysis. RNA data were normalized by added spike-ins, and results are reported under 5% false discovery rate.

Results: In this primary cell model, SAHA was characterized by an increase in viral transcripts at both 8h and 24h post-treatment as compared to DMSO, while increase in viral transcripts upon TCR stimulation was observed mostly at 24h. Enhancement of virally-encoded GFP expression was observed mainly upon TCR stimulation, regardless of SAHA addition. Analysis of variance on transcriptome profiles performed over 14,036 genes revealed that TCR stimulation altered the expression of 8384 genes, enriched for cell metabolism and cell cycle among other pathways, and consistent with the induction of a cellular environment supportive of viral replication. Addition of SAHA dampened the transcriptional response to TCR stimulation: the two responses were anti-correlated (r=-0.19, p<10^-109). In particular, a fraction of TCR regulated genes (n=1064, 13%) showed a significant non-additive response upon SAHA co-administration, which was highly dominated by antagonistic effects (n=953, 90%), suggesting a negative interaction between the two treatments.

Conclusions: The current data suggest that activation of cells treated with SAHA does not improve translation of viral transcripts beyond effects from cellular activation alone. On the contrary, transcriptome analysis indicates that SAHA antagonizes the expression of numerous genes that depend on TCR signaling.

435LB HIV-1 Expression Within Resting CD4 T-Cells Following Multiple Doses of Vorinostat In Vivo
Yang Kuo-Hsiung1, Nancie M. Archin2, Christopher H. Woelk3, Matthew C. Strain4, Douglas D. Richman4, JoAnn D. Kuruc5, Richard J. O. Barnard5, Daria J. Hazuda5, Joseph J. Eron5, David M. Margolis2
1School of Pharmacy, UNC Chapel Hill, Chapel Hill, NC, United States; 2School of Medicine, UNC Chapel Hill, Chapel Hill, NC, United States; 3University of Southampton, Southampton, United Kingdom; 4School of Medicine, UCSD and San Diego VAMC, San Diego, CA, United States; 5Merck Research Laboratories, White Horse Junction, PA, United States

Background: A single dose of the potent class I histone deacetylase inhibitor (HDACi), vorinostat (VOR) upregulates HIV RNA expression within the resting CD4+ T cells of antiretroviral (ART)-treated, aviremic HIV+ patients. The ability of VOR to repeatedly disrupt latency is unproven, the optimal dosing schema is unknown, and the effect of repeated VOR exposure on host mechanisms that might contribute to viral expression is uncertain.

Methodology: In a Phase I-II single-center study, HIV+ participants maintained suppressive ART, and resting CD4+ T cells were obtained for study via leukapheresis. Following a single VOR 400 mg dose, an increase in resting CD4+ T cell-associated HIV RNA (rc-RNA) was measured in all patients (Archin, Nature 2012), and consenting patients later received VOR 400 mg daily Monday-Wednesday for 4 weekly cycles, followed after a 4-8 week rest period by another 4 weekly cycles. VOR serum concentrations ([VOR])), measurements of histone acetylation within PBMCs, rc-RNA, total cellular HIV DNA, and quantitative viral outgrowth assays (QVOA) from resting CD4+ T cells were obtained. A population PK model was built from all available [VOR] data using nonlinear mixed effects modeling with NONMEM 7.2. The model was used to predict individual [VOR] at the time of leukapheresis and perform exploratory exposure-effect relationships.

Results: In 5 patients VOR was well tolerated with no adverse events > Grade I; mild declines in platelet counts < Grade I were seen at late time points. Repeat dose [VOR] were similar to single dose. However, when measured by leukapheresis after dose 11 (2nd dose of cycle 4) and dose 22 (2nd dose of cycle 8) cellular histone acetylation was little increased from baseline, and measures of rc-RNA only modestly increased in some patients. QVOA and other assays were not significantly affected. [VOR] corresponding to the leukapheresis measurements show an exposure-effect relationship with clock-wise hysteresis, signifying tolerance to VOR over time.

Conclusions: The results of this study suggests that HIV latency is disrupted by an initial VOR dose, but a refractory period of more than 24 hours ensues, which may reduce the responsiveness of the viral promoter to HDACi induction. Attempts to use HDACis to deplete persistent HIV infection will require a detailed understanding of the kinetic effects of HDACis on host cellular functions. Gene expression analysis to understand the complex cascade of events that follow VOR exposure in vivo are ongoing.

436 Autophagy Induction by Histone Deacetylase Inhibitors Inhibits HIV-1 Infection in Macrophages
Grant R. Campbell, Rachel S. Bruckman, Stephen A. Spector
University of California San Diego, La Jolla, CA, United States

Background: Histone deacetylases inhibitors (HDACi) have been shown to induce HIV production from latently infected cells in vitro with the aim to enhance elimination of these cells and achieve a cure. However, the activity of these drugs in non-T-cell reservoirs is unknown. In this study, we investigated the effect of HDACi on the induction of autophagy, and in the replication of HIV within human primary macrophages.

Methodology: Monocyte-derived macrophages (MDM) were treated with HDACi (romidpesin, vorinostat, belinostat, givinostat, or panobinostat) at sub-cytotoxic concentrations and assessed for autophagic flux using the expression and phosphorylation of autophagy proteins and the lipidation of microtubule-
associated protein 1 light chain 3B (LC3B) by immunoblotting, qRT-PCR, and fluorescence microscopy. MDM were challenged with 10^5 TCID_{50} HIV-1_{Ba-L} per 5 x 10^5 cells, and replication assessed using HIV p24 antigen release into culture supernatants. The role of autophagy in the HDACi-mediated inhibition of HIV infection was investigated using small molecule inhibitors or by transducing MDM with shRNA for BECN1 or ATG5. Data were analyzed using the Mann-Whitney U test.

**Results:** HDACi induced autophagic flux in MDM in a dose-dependent manner (belinostat < givinostat < vorinostat < panobinostat < romidepsin) as demonstrated by increased lipidation of LC3B, degradation of sequestosome and increased autophagosome formation (P < 0.05) in the absence of increased cell death. We also identified that HDACi induces autophagy through a ULK1 complex-dependent mechanism by suppressing MTOR activity as indicated by the dephosphorylation of RPS6KB2, EIF4EBP1 and ULK1, the most upstream and essential component of the classical autophagy pathway. HDACi induced autophagy significantly inhibited HIV-1 replication in macrophages over 10 days in a dose-dependent manner that reflected autophagy induction (P < 0.001) and was abrogated in the presence of RNAi for autophagy proteins or chemical inhibitors of autophagic flux (P > 0.05).

**Conclusions:** HDACi induces autophagy in human macrophages by releasing the ULK1 complex from inhibition by MTOR-mediated phosphorylation possibly as a prosurvival mechanism to counteract their cytotoxic effects. If HDACi are to form part of a multi-pronged strategy to eliminate latently infected cells with the ultimate goal of a functional or sterilizing cure for HIV, careful consideration of toxicity as well as activity in non-T-cell reservoirs is essential. These data support an important role for autophagy in the control of HIV infection, and provide new insights into novel approaches to inhibit HIV-1 replication and potentially eradicate the virus from infected cells.

**An In Vitro Compound Screen for Selective Apoptosis Induction in HIV-1 Infected Resting CD4+ T Cells**

Adam M. Spilvak, Alberto Bosque, Vicente Pianelles

1Medicine, University of Utah School of Medicine, Salt Lake City, UT, United States, 2Pathology, University of Utah School of Medicine, Salt Lake City, UT, United States

**Background:** Despite the ability of antiretroviral therapy to suppress viral replication, proviral HIV-1 persists in resting memory CD4+ T cells. These cells, termed the latent reservoir, represent a major barrier to HIV-1 eradication. One strategy to purge this reservoir, termed “shock and kill”, aims to induce proviral transcription without inducing cellular activation (the “shock”) with subsequent elimination of these cells via viral cytopathic effect or immune system targeting (the “kill”). While a number of promising candidate “shock” compounds have been identified, ongoing research suggests that “shocked” T cells do not undergo cell death. Novel strategies to eliminate these cells may be necessary for the “shock and kill” approach to deplete the latent reservoir. We hypothesize that resting central memory CD4+ T cells (Tcm) expressing HIV-1 genes are phenotypically distinct from their uninfected and latently infected counterparts and can be selectively targeted for apoptosis.

**Methodology:** We designed an in vitro screening assay to evaluate for selective apoptosis induction among Tcm actively expressing HIV-1 genes. Naïve CD4+ T cells from healthy donors were activated by T cell receptor stimulation and progressed to a quiescent state determined by morphology and loss of activation markers. 10 days post-activation they were infected with eGFP-pseudotyped HIV-1. Screening was performed with a chemical compound library containing 160 cell-permeable protein kinase inhibitors. Apoptosis among infected (GFP+) and uninfected (GFP-) cells was detected by flow cytometry. Screening hits were defined as compounds that induced apoptosis among GFP+ cells greater than three standard deviations (SD) above the apoptosis mean from negative control wells. Compounds inducing apoptosis >3SD above baseline in both GFP+ and GFP- cells were excluded as non-specific.

**Results:** We identified two kinase inhibitors, HA1077 and kenpaullone, that reproducibly and selectively target HIV-1 infected resting Tcm for apoptosis in independent experiments using cells from multiple donors. HA1077 is a Rho kinase inhibitor and kenpaullone is an inhibitor of multiple cyclin-dependent kinases and glycogen synthase kinase 3α and β. These compounds appear to be non-toxic and trigger minimal bystander cell apoptosis.

**Conclusions:** We have developed a novel primary cell screening assay to identify compounds that selectively induce apoptosis in HIV-1 infected resting Tcm. Using a commercial kinase inhibitor library we have identified two reproducible compound hits to date. These compounds, and the mechanisms by which they selectively induce apoptosis in HIV-1 infected cells, merit further exploration. These results may help to further ongoing HIV-1 eradication strategies.

**438LB Panobinostat Induces HIV Transcription and Plasma Viremia in HIV Patients on Suppressive cART**

Thomas Rasmussen, and the CLEAR study group

Dept. of Infectious Diseases, Aarhus University Hospital, Aarhus, Denmark

**Background:** Reactivating HIV-transcription is currently investigated as a strategy to eliminate latently infected cells. We aimed to evaluate the ability of the potent histone deacetylase inhibitor (HDACi) panobinostat to reverse HIV latency. panobinostat to reverse HIV latency.

**Methodology:** In a phase I/II clinical trial, HIV-infected adults received oral panobinostat 20 mg 3 times/week every other week for 8 weeks while maintaining combination antiretroviral therapy (cART). The primary endpoint of cell-associated unspliced HIV-RNA (CA-US RNA) was analyzed in total CD4+ T cells using semi-nested qPCR. Secondary endpoints included safety, plasma HIV-RNA, as well as total and integrated HIV-DNA. Changes from baseline were analyzed using repeated measurement analysis of variance and paired t-test or Wilcoxon signed-rank test. Binary outcomes were analyzed using a logistic model with a random effect for each patient.

**Results:** Fifteen patients were included and all completed full panobinostat dosing and follow up. Levels of CA-US RNA increased significantly during panobinostat treatment (p<0.0001) with significant increases on time points on-treatment as compared to baseline. The median maximal fold-increase in CA-US RNA was 3.5 (range 2.1-14.4). Levels of CA-US RNA remained elevated 4 weeks post-panobinostat (fold-increase 1.60; 95% CI: 1.17-2.19; P=0.003). Using a transcription mediated amplification-based semi-quantitative assay (Procleix Ultrio Plus, 59 % analytic sensitivity of 3.6 copies/mL), HIV-RNA in plasma was detected more frequently during panobinostat administration with an odds ratio of 10.5 (95% CI: 2.2-50.3) for a positive test.
on-treatment compared to baseline. Sixteen adverse events (AEs) were presumed related to panobinostat; these occurred in 10 patients and were all grade 1 AEs. Fatigue was the most frequently reported drug-related AE. CD4+ T cell counts were unaffected by panobinostat treatment. The level of total HIV DNA/106 CD4+ T cells decreased transiently from baseline to day 14 (P=0.040), but returned to baseline level at subsequent time points in most patients. There was no change from baseline in integrated HIV DNA.

Conclusions: Eight weeks of cyclical therapy with panobinostat was safe and well tolerated. Panobinostat treatment caused a significant increase in CA-US HIV-RNA levels, increased detection of plasma HIV RNA as well as a transient decrease in total HIV DNA. Our results show that Panobinostat efficiently induces HIV transcription and is a promising candidate for future combination strategies to reactivate and eliminate the latent HIV reservoir.

439 Failure of HIV-1 To Replicate in Human T Cells Expressing a Tat Mutant
David Harrich, Hongping Jin, Lin Rustant, Ann Apolloni, Haran Sivakumarun, Min-Hsuan Lin, Dongsheng Li, Ting Wei
Cell and Molecular Biology, OIRM Berghehoer, Herston, QLD, Australia

Background: Our research indicates that Nullbasic[1] is possibly the strongest anti-HIV protein tested. Nullbasic inhibits HIV replication at 3 distinct steps of the viral life cycle: transcriptional activation by Tat, Rev-mediate RNA transport and HIV reverse transcription[1-3]. As Nullbasic opposes transactivation by Tat, a key step in the activation of latently infected T cells, we hypothesized that Nullbasic might enforce latency in infected cells. Previously we showed that Jurkat and primary human cells[3] expressing Nullbasic were strongly protected from HIV replication. Recently Nullbasic expression was improved by using new lentiviral vectors. Our results showed that Nullbasic is stably expressed by T cell lines. Hence we performed in vitro and animal experiments to determine the effectiveness of Nullbasic to protect cells from HIV and to oppose activation of HIV in latently infected T cells.

Methodology: A gene encoding Nullbasic-FLAG-ZsGreen1 or ZsGreen1 was inserted into a modified lentiviral vector. VLPs were used to transduce Jurkat T cells and primary human CD4+ cells. Transduced cells were incubated with HIV and virus infectivity and replication assays were performed. Analysis of viral CDNA synthesis and proviral DNA integration was undertaken. Total cellular mRNA profiling of Jurkat cells expressing Nullbasic was performed. Analysis of HIV latency and activation of HIV-1 using PMA, SAHA, TNF-alpha and prostratin in latency model T cell lines expressing Nullbasic was undertaken. HIV replication and the stability of the transduced primary human cells were investigated in humanized Rag2-/-;γc-/- mice.

Results: In repeated experiments, results showed that Jurkat cells expressing Nullbasic completely inhibited HIV replication for months. Similar results were observed using primary CD4+ human lymphocytes. Nullbasic can strongly inhibit HIV activation in ACH2 and U1 models of viral latency. J-Lat cells were protected to a much smaller degree if stimulated with TNF-alpha and prostratin. Differential Illumina™ mRNA expression analysis of Jurkat-Nullbasic were observed using primary CD4+ human lymphocytes. Nullbasic can strongly inhibit HIV activation in ACH2 and U1 models of viral latency. J-Lat cells

Conclusions: Here we confirm that Nullbasic is an excellent candidate for a gene therapy approach to protect human cells from HIV infection. Nullbasic appears to exhibit no cellular toxicities unlike the HIV Tat protein from which it is derived. Our data suggest that Nullbasic can protect cells from infection as well as suppress the activation of latent HIV.

440 Hepatitis C Therapy Reduces CD4 T-Cell-Associated HIV-1 DNA in HIV-1/HCV Coinfected Patients
Hong Sun 1, 2, Maria Buzon1, Amy Shaw4, Randi Berg4, Xu G. Yu4, Sara Ferrando-Martinez5, 6, Manuel Leah5, 7, Ezequiel Ruiz-Mateoci5, 7, Mathias Lichterfeld5
1Ragon Institute of MGH, MIT, and Harvard, Boston, MA, United States, 2Key Laboratory of AIDS Immunology, Department of Laboratory Medicine, First Affiliated Hospital of China Medical University, Shenyang, China, 3Infectious Disease Division, Massachusetts General Hospital, Boston, MA, United States, 4Infectious Disease Division, Aarhus University Hospital Skejby, Aarhus, Denmark, 5Laboratory of Immunovirology, Biomedicine Institute of Seville, Division of Infectious Diseases, Microbiology and Preventive Medicine, Virgen del Rocio University Hospital, University of Seville, Seville, Spain, 6Laboratorio Inmunobiología Molecular, Hospital General Universitario Gregorio Marañón, Madrid, Spain, 7Consejo Superior de Investigaciones Científicas, Madrid, Spain

Background: Hepatitis C treatment with Interferon-α (IFN-α) and Ribavirin (RBV) can effectively cure HIV infection in a significant proportion of patients, but effects of this regimen on cellular reservoirs for HIV-1 are unknown. This study aimed at elucidating the effects of combined therapy with IFN-α and Ribavirin against HIV-1 infected cells in HIV-1/HCV co-infected patients receiving suppressive antiretroviral therapy.

Methodology: CD4 T cells were isolated from a cohort of HIV-1/HCV co-infected patients who received suppressive HAART and HCV treatment with IFN-α and Ribavirin (n=12). CD4 T cells collected from time intervals immediately before or after therapy with IFN-α/RBV were used for comparison. Cell-associated HIV-1 DNA was measured using established PCR protocols. In vitro HIV-1 reactivation assays were performed using PBMCs from HAART-treated HIV-1 infected patients. Wilcoxon paired rank test was used to test for statistical differences.

Results: CD4 T cell-associated HIV-1 DNA remained stable during time periods prior to IFN-α/RBV therapy. During exposure to IFN-α/RBV, a moderate, but significant (p<0.02) and sustained decline of HIV-1 DNA was observed in CD4 T cells. This decline of HIV-1 DNA was inversely correlated to IFN-α-associated CD4 T cell losses. However, in vitro experiments failed to demonstrate an effect of pharmacological doses of IFN-α on HIV-1 reactivation, suggesting that the reduction of HIV-1 DNA during treatment with IFN-α or IFN-α/RBV is not due to direct effects of IFN-α or IFN-α/RBV on HIV-1 reactivation from latency.

Conclusions: These data demonstrate that Hepatitis C treatment with IFN-α/RBV can moderately reduce the reservoir of HIV-1 infected CD4 T cells that persists despite suppressive antiretroviral therapy in HIV-1/HCV co-infected patients. Exploring the mechanisms underlying the reduction in HIV-1 DNA during IFN-α/RBV therapy may be helpful for designing improved clinical strategies for HIV-1 eradication.
HIV-1 Nef Inhibits Autophagy in Macrophages Through Transcription Factor EB Sequestration

Grant R. Campbell, Pratima Rawat, Rachel S. Bruckman, Stephen A. Spector
University of California San Diego, La Jolla, CA, United States

**Background:** Transcription factor EB (TFEB) is a master gene expression regulator of the classical autophagy-lysosome pathway. Under basal conditions, TFEB is phosphorylated by MTORC1, resulting in the cytoplasmic retention of TFEB through interactions with 14-3-3 proteins. When MTORC1 is inhibited, TFEB is dephosphorylated, prompting its translocation to the nucleus where it increases the expression of genes encoding lysosomal proteins. HIV-1 Nef acts as an anti-autophagic maturation factor through interaction with beclin-1, an essential autophagy and tumor suppressor protein. In this study, we investigated the role of Nef and TFEB in the modulation of autophagy during HIV-1 infection of human macrophages.

**Methodology:** Monocyte-derived macrophages (MDM) were challenged with $10^5$ TCID$_{50}$ HIV-1$_{Ba-L}$ or HIV-1$_{ΔNef}$ per $5 \times 10^6$ cells. Autophagy and the role of TFEB was assessed using the expression, localization, and phosphorylation of autophagy proteins combined with the lipidation of microtubule-associated protein 1 light chain 3B (LC3B) by immunoblotting, qRT-PCR, and fluorescence microscopy or by transducing MDM with shRNA for TFEB. Data were analyzed using the Mann-Whitney U test.

**Results:** Following exposure of macrophages to HIV-1$_{Ba-L}$ or heat-inactivated HIV-1, TFEB is dephosphorylated and translocated to the nucleus. This correlated with an increase in autophagy as evidenced by increased lipidation of LC3B, degradation of sequestosome, and increased autophagosomal formation ($P < 0.01$) and was attenuated by TFEB silencing ($P < 0.05$). In the presence of productive infection, TFEB phosphorylation and cytoplasmic sequestration started to increase and autophagy markers decrease by 5 days post-infection and by 7 days, levels were similar to the uninfected controls ($P > 0.05$). HIV-1$_{ΔNef}$ similarly induced the dephosphorylation and nuclear localization of TFEB that corresponded to an increase in autophagy during initial infection. Conversely, at 7 days post-infection nuclear accumulation of dephosphorylated TFEB and autophagy markers remained elevated ($P < 0.02$).

**Conclusions:** These results support a model whereby, during initial infection, the interaction between virion surface proteins and host receptors serve as a signal for autophagy initiation that is dependent upon the dephosphorylation and nuclear translocation of TFEB mediated by the inhibition of MTORC1. Once HIV-1 establishes a productive infection, Nef down regulates autophagy through the phosphorylation and cytosolic sequestration of TFEB. These findings help to explain how HIV-1 modulates autophagy to promote its own replication and cell survival, and further suggests that disrupting the autophagic balance within the infected cell can inhibit HIV-1 and potentially eliminate the infected cell.

---

HIV-1 RNA Detection in CSF in ART-Treated Subjects With Incomplete Viral Suppression in Plasma

Sam Nightingale, the PARTITION Study Group
Institute of Infection and Global Health, University of Liverpool, Liverpool, United Kingdom

**Background:** It has been proposed that HIV replication may continue in sanctuary sites such as the brain due to suboptimal antiretroviral drug penetration or activity. The aims of this study were to investigate HIV-1 RNA levels in cerebrospinal fluid (CSF) of subjects on ART and relate the findings to HIV-1 RNA detection in plasma.

**Methodology:** The UK PARTITION study obtained paired CSF and plasma samples from two groups; group A - undergoing investigation for possible neurological disease; group B - unexplained intermittent or persistent HIV-1 RNA detection $>50$ copies/mL within the previous 12 months in the absence of neurological disease. HIV-1 RNA levels were measured by a modified Abbott RealTime assay, achieving a sensitivity of detection of 1-3 copies/mL. CSF/plasma discordance was defined as HIV-1 RNA levels differing by $>0.5$ log$_{10}$ copies/mL. Residual plasma HIV-1 RNA detection was defined as a level between 1 and 49 copies/mL. ART concentrations were determined in CSF and plasma by tandem mass spectrometry.

**Results:** 152 subjects were recruited; 114 in group A and 38 in group B. In the total study population, median HIV-1 RNA levels were 10 copies/mL (IQR 5-103) in plasma and 5 copies/mL (IQR 1-186) in CSF ($p = 0.032$). Among 64 subjects with plasma HIV-1 RNA $<50$ copies/mL, 47 had residual plasma HIV-1 RNA detection. In these 47 patients, HIV-1 RNA levels in CSF were median 5 copies/mL (IQR 3-186) in CSF ($p = 0.032$). Among 10 subjects (group A n=6), with CSF/plasma discordance and median CSF levels of 208 copies/mL (IQR 114-1274). Of the 17 subjects with no residual HIV-1 RNA detection in plasma, none had detectable HIV-1 RNA in CSF ($p = 0.037$).

Overall, 8/38 subjects in group B (21%) had CSF/plasma discordance, with median HIV-1 RNA levels of 911 copies/mL (IQR 156-2330) in CSF and 42 copies/mL (IQR 12-81) in plasma.

CSF/plasma discordance was not was not associated with CNS penetration effectiveness score. No correlation between CSF concentrations of darunavir, raltegravir, efavirenz and atazanavir and HIV-1 RNA detection in CSF were observed.

Three discordant CSF samples were sequenced to determine the drug resistance profile; two samples from patients on emtricitabine showed the reverse transcriptase (RT) mutation M184I; the third sample from a heavily pre-treated patient showed multiple RT mutations comprising TAMs ($D67N$, $K70R$, $T215Y$, $K219E$), $L74V$ and $M184V$ for NNRTIs, and $L101I$ and $K103N$ for NNRTIs.

**Conclusions:** The CNS may be the source of ongoing HIV-1 replication in a proportion of patients that fail to suppress below 50 copies/mL in plasma, as well as those with residual plasma HIV-1 RNA detection between 1-49 copies/mL. This has implications for the management of low-grade viremia and ‘blips’, both in terms of stratifying lumbar punctures and tailoring treatment for effective suppression in the CNS.

**CSF Viral Escape in Patients Without Neurological Disorders: Prevalence and Associated Factors**

Carmela Pinnetti1, Patria Lorenzin1, Federica Forbici1, Adriana Ammassari1, Raffaella Libertone1, Maria Letizia Giancola1, Maria Rosaria Capobianchi1, Carlo Federico Perno2, Andrea Antinori1

1National Institute for Infectious Disease, Rome, Italy; 2University of Rome, Rome, Italy

**Background:** CSF viral escape (CVE) is an emerging issue in the HIV setting and has been associated with neurologic symptoms and neurocognitive impairment. Few studies have estimated CVE prevalence and factors associated.

**Methodology:** Single-center retrospective study on CSF/plasma paired samples obtained from HIV-patients undergoing spinal tap because of neurological signs/symptoms or CNS stage of systemic diseases. Patients with diagnosis of CNS disorders were excluded. Repeated CSF/plasma samples obtained from the same patient were included if collected while receiving different cARTs. CVE was defined: a) detectable CSF HIV-RNA with concurrent plasma levels <50 copies/mL; b) CSF HIV-RNA >1.0 log higher than concomitant plasma RNA level. Adjusted ORs of CVE were calculated by fitting a logistic multivariate regression model.

**Results:** 303 CSF/plasma pairs collected from 115 patients were included: 88% male, median age 48 (IQR 41-52), HIV acquisition heterosexual in 43%, MSM in 21%, IDU in 27%. CD4 count was <200 cells/mm3 in 48% and >350 in 25%; 31% were CDC stage C. CSF was collected in 14% during 1994-2004, in 48% during 2004-2008, in 37% during 2009-2013. At the time of collection, 50% were on cART with TDF/FTC, 12% with ABV/3TC, 9% with ZDV/3TC, 33% with EFV, 33% with LPV/r/ 12% with ATV/r. CVE was detected in 32/303 samples (10.6%). At multivariable analysis, male gender (OR 0.23; 95%CI 0.07-0.76), CD4 >350 (0.22; 0.06-0.73) and 2009-2013 period (0.05; 0.00-0.25) were all independently associated to a decreased risk of CVE. Fitting a separate logistic model including ARVs and using TDF/FTC as reference, both ABV/3TC (OR 8.20; 1.61-41.65) and ZDV/3TC (OR 11.12; 1.62-76.35) were related to an increased CVE risk. In the same model, having EFV as reference, ATV/r (OR 5.67; 0.98-32.72) was related to a higher risk of CVE. Age, duration of cART and 2010 CPE score were not associated with CVE. A sensitivity analysis including only 151 patients with plasma HIV-RNA <50 copies/mL, found 22 CVE (12.5%). At logistic regression, the protective effect of male gender, CD4 >350, 2009-2013 period was confirmed. Among ARVs, only the increased risk associated with ABV/3TC use when compared to TDF/FTC remained significant.

**Conclusions:** In this large record of CSF/plasma paired samples from patients without CNS disorders, CVE occurred in about 10% of cases, with a reduced frequency in recent years. Male gender and higher CD4 count had a protective role. Though channeling bias in this cross-sectional study cannot be ruled out, the lack of correlation of CVE and CPE score, and the protective role of TDF/FTC (versus ABV/3TC or ZDV/3TC) and of EFV (versus ATV/r) suggest that effective viral suppression in plasma more than neuropenetrative effectiveness of ARVs may drive the control of HIV replication in CSF.

**Early Monocyte Inflammation Among Treatment-Naïve Acute HIV-Infected Thai Subjects**

Lishomwa C. Ndhlovu1, Mary Margaret Byron1, Guangxiang Zhang1, Duangbalthai Sutthichom2, Somprarthana Rattanamanee3, Rapee Trichavaroj3, Nittaya Phanuphak4, Victor Valcour5, Merlin Robb6, Jintanat Ananworanich7

1Hawaii Center for AIDS, University of Hawaii, Honolulu, HI, United States, 2University of Hawaii, Honolulu, HI, United States, 3SEARCH, The Thai Red Cross AIDS Research Center, Bangkok, Thailand, 4Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, 5University of California San Francisco, San Francisco, CA, United States, 6US Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States, 7SEARCH, HIV-NAT, The Thai Red Cross AIDS Research Center, Bangkok, Thailand

**Background:** Monocytes (MO) are a heterogeneous population of myeloid cells defined into 3 distinct subsets based on CD14 and CD16 expression as classical (CD14highCD16-), non-classical (CD14lowCD16++) and an intermediate (CD14highCD16+) subset. It is suggested that CD16 expressing MO changes that occur in the earliest stages of HIV infection may be mechanistically relevant to the persistence of cognitive complications in patients despite suppressive antiretroviral therapy (ARV).

**Methodology:** We characterized MO inflammatory phenotype and functional responses (IL-6, IL-1β and TNF-α) by a novel multiparametric flow cytometric technology in a prospective study of 17 ART-naïve acute HIV-infected (AHI) individuals, captured during a hyper-acute window during Fiebig stage I (RNA+/ HIV IgM-, n=10) and III (HIV IgM+/IgG-, n=7) before appreciable antibody response can be measured and correlated to clinical parameters of disease progression (eg: plasma HIV Viral load). Wilcoxon rank sum tests were conducted to compare the differences between Fiebig stages.

**Results:** We observed that subjects captured in Fiebig I had lower plasma HIV viral load compared to subjects in Fiebig III; median (Interquartile range) = 4.3 log10 copies/ml (3.6,5.4) vs 5.5 log10 copies/ml (5.4,7.5); p=0.01. Cross-sectionally, Fiebig I subjects had a greater frequency of only non-classical MO compared to Fiebig III (18.2% (8.7,26.9) vs 7.4% (4.4,12.1); p=0.03). Lipopolysaccharide (LPS) stimulated IL-6+ MO responses were greater in Fiebig I compared to Fiebig III (14.5% (7.7,17.7) vs 5.3% (4.9,9.3); p=0.04). No differences in either basal or LPS stimulated IL-1β or TNF-α MO responses were seen between Fiebig stages. Plasma HIV viral load was inversely associated with both basal (r=-0.603;p=0.008) and LPS (r=-0.562; p=0.015) stimulated IL-6+ MO responses.

**Conclusions:** These results indicate that the presence of HIV soon after infection differentially alters the inflammatory profile of various MO subsets and precedes peak viremia in AHI. Tracking MO inflammation after early institution of ARV therapy in AHI may have significant implications in reducing HAND.
445 Cerebrospinal Fluid Viral Blips and Persistent Escape in HIV-Infected Patients On ART

Arvid Edén1, Lars-Magnus Andersson2, Dietmar Fuchs3, Lars Hagberg, Staffan Nilsson1, Bo Svennerholm1, Aylin Yilmaz4, Henrik Zetterberg1, Magnus Gisslen1
1University of Gothenburg, Gothenburg, Sweden, 2Innsbruck Medical University, Innsbruck, Austria, 3Chalmers University of Technology, Gothenburg, Sweden

Background: Cerebrospinal fluid (CSF) viral escape, where HIV-1 RNA is increased in CSF while suppressed in plasma, has previously been shown to occur infrequently in subjects responding well to antiretroviral therapy (ART). It is unclear if CSF viral escape represents a continuous low-grade CNS infection in some patients, and may constitute a risk for future neuronal damage. The light subunit of the neurofilament protein (NLF) is a component of myelinated axons, and elevated concentrations in CSF are a sensitive marker of ongoing axonal injury in HIV-associated dementia (HAD). To investigate the frequency of CSF viral escape in relation to neuronal damage, we analyzed NFL in a longitudinal cohort of subjects responding well to ART.

Methodology: Subjects on effective ART ≥6 months with plasma HIV-1 RNA <50 c/ml at inclusion, followed with ≥2 lumbar punctures for CSF analysis were identified from a longitudinal study. Subjects with CNS opportunistic infections or other significant CNS disease were excluded from the analysis. Transient low increases in plasma viral load (“blips”) during the study period were allowed. HIV-1 RNA was analyzed with real-time PCR (Cobas TaqMan, Roche). CSF concentrations of NFL were measured by an enzymatic 2-site quantitative immunoassay (UmanDiagnostics, Umeå, Sweden). CSF neopterin was measured by ELISA. The relationship between CSF NFL levels and age were analyzed with a linear mixed effects model. Mann Whitney U-test was used for group wise comparison.

Results: Seventy-five (52 male, 23 female) patients with multiple CSF analyses (median 5, range 2-14) were included in the analysis. 26 (35%) had CSF RNA above quantification limit (20 c/ml) on at least one time point (median 50, IQR 32-78 c/ml); 6 (8%) had increased CSF RNA in consecutive samples. 40 (53%) patients had ≥1 (range 0-6) transient plasma HIV-1 RNA >20 c/ml (median 44; IQR 29-71 c/ml). In 8 samples, RNA was >20 c/ml in both CSF and plasma. Of all 373 tested samples, 38 (10%) and 74 (20%) were >20 c/ml in CSF and plasma, respectively. CSF neopterin was higher in samples with increased (median 7.3, IQR 6.4-11 nmol/l) than with undetectable (median 6.4, IQR 5.1-7.7 nmol/l) CSF HIV-1 RNA (p<0.05). No similar difference was found in CSF NFL.

Conclusions: In this longitudinal analysis we found that occasional increased CSF HIV-1 RNA was not uncommon in patients on effective ART, although less frequent than in plasma. A minority of subjects had persistently increased CSF virus which may represent CSF viral escape. Increased CSF HIV-1 RNA was related to a higher level of intrathecal immune activation. However, we found no correlation between CSF HIV-1 RNA and NFL, suggesting that increased CSF virus and immune activation does not result in CNS axonal injury in patients on ART, at least not in the short term.

446 Mitochondrial DNA Is Associated With Inflammation and Neurocognitive Deficits in HIV Infection

Josué Pérez-Santiago1, Sanjay R. Mehta2, Sara Gianella1, Rachel D. Schrier1, Mariana Cherner1, Susanna R. Var1, Tyler R. C. Day1, Miguel Ramirez-Gaona2, Davey M. Smith1, 2, Scott L. Letendre1
1Medicine, University of California San Diego, La Jolla, CA, United States, 2Bioinformatics, University of Alberta, Edmonton, AB, Canada, Veterans Administration San Diego Healthcare System, San Diego, CA, United States

Background: HIV enters the central nervous system (CNS) early in infection leading to persistent inflammation and often resulting in HIV associated neurocognitive disorders (HAND). Cells in the CSF tend to be activated and inflammatory factors may increase cell death, releasing mitochondrial DNA (mtDNA) into the cerebrospinal fluid (CSF). MtDNA itself can induce a potent inflammatory response and may contribute to the persistent inflammation in the CNS. We hypothesized that higher levels of free mtDNA in CSF would be associated with higher levels of immune activation, pro-inflammatory cytokines, and chemokines, as well as with worse neurocognitive performance.

Methodology: We performed a retrospective evaluation of CSF supernatant samples collected from 31 HIV infected individuals enrolled in an NIMH-funded cohort, 16 of whom had available longitudinal assessments. Neurocognitive performance, summarized by the global deficit score (GDS), sociodemographic and clinical data were collected for each participant. Neurocognitive impairment (NCI) was defined as a GDS ≥ 0.5. We quantified mtDNA load (ML) in CSF using the highly sensitive droplet digital PCR platform. Biomarkers of immune activation (sCD14 and sCD163), pro-inflammatory cytokines (TNF-α, IL-6), and chemokines (MCP-1, IP-10) were measured using immunoassays. Statistical analyses were performed using R software.

Results: Using mixed effects regression analysis and all samples available, a higher ML in CSF was associated with greater neurocognitive dysfunction (GDS, p=0.002), higher levels of the CNS inflammatory chemokines IP-10 (p=0.03) and sCD14 (p=0.01). In cross-sectional analysis, the association of ML with CNS inflammation was more prominent in the subgroup of patients with a detectable CSF HIV VL (IP-10, r=0.7, p=0.001), and the subgroup of patient with a CD4 count <350 (IP-10, r=0.68, p=0.03). In this latter subset, ML also correlated with CD4 nadir (r=0.71, p=0.03). When NCI was present, a higher ML in CSF correlated with greater neurocognitive dysfunction (GDS, r=0.78, p=0.001), increased CNS levels of the inflammatory chemokine IP-10 (r=0.7, p=0.001), and increased plasma levels of the inflammatory chemokine MCP-1 (r=0.67, p=0.01). However, there was no association between CSF VL and GDS, and IP-10 was only weakly associated with GDS (r=0.53, p=0.06).

Conclusions: Extracellular mtDNA may represent a novel biomarker of neurologic damage that not only is easily measurable in CSF, but also may associate better with neurocognitive dysfunction than other biomarkers. Additionally, mtDNA may contribute to persistent inflammation of the CNS seen in HIV infection. A better understanding of the role of mtDNA in the CNS inflammation could lead to improved therapies for HAND.
447 CNS Outcomes of cART vs. cART plus Maraviroc and Raltegravir Intensification During Acute HIV
Victor Valcour1, Serena Spudich1, Napaporn Sailasuta2, Sukalaya Lerdlum2, James L. K. Fletcher3, Eugene D. M. B. Kroon4, Peeriya Mangyu5, Bonnie Slike6, Jerome Kim7, Jintanat Ananworanich8, on behalf of the SEARCH 010/RV254 Study Group
1Memory and Aging Center, UCSF, San Francisco, CA, United States, 2Neurology, Yale University, New Haven, CT, United States, 3Huntington Medical Research Institutes, Pasadena, CA, United States, 4Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, 5SEARCH, The Thai Red Cross AIDS Research Center, Bangkok, Thailand, 6U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Springs, MD, United States, 7Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand

Background: Within weeks of HIV infection, HIV RNA is found in cerebrospinal fluid (CSF) with accompanying changes in brain parenchyma by magnetic resonance spectroscopy (MRS) supporting theories of early CNS seeding with virus. Intensification of cART with CCR5 and integrase inhibitors is strategized to limit HIV reservoirs when instituted early after HIV infection. The impact of cART intensification on CNS outcomes, when instituted during the earliest stages of infection is not known. We investigated change in inflammatory markers using MRS and CSF cytokines among subjects randomized to cART (efavirenz (EFV), tenofovir (TFV), emtricitabine (FTC), n=25) vs. cART+ (cART+ + raltegravir (RAL) and maraviroc (MVC)).

Methodology: 62 acute HIV subjects (31 cART and 31 cART+) underwent MRS for N-acetyl aspartate (NAA), choline (CHO), myo-inositol (MI), and glutamate/glutamine (Glx) at basal ganglia (BG), parietal gray matter (PG), frontal white matter (FW), and frontal gray matter (FG) during acute HIV (Fiebig stage I-IV) then at 12 and 24 weeks after cART vs. cART+ randomization. Subjects intolerant to EFV (n=3) or with resistance (n=1) in the cART arm were switched to RAL whereas EFV was discontinued for those intolerant (n=5) or resistant (n=1) in the cART+ arm. CSF was sampled for HIV RNA, IL-6, IP-10, MCP-1 and neopterin at baseline and 24 weeks after randomization. Comparisons employed regression models across visits for MRS and comparison of baseline to last sampling for MRS and log10 transformed cytokines.

Results: Enrollment occurred a mean (range) of 17 (4-40) days after estimated HIV exposure. Mean (SD) age was 29 (7.3) years and 94% were male with no differences by arm. 50 cases underwent MRS at baseline (25 cART and 20 cART+) and 43 at week 24 (25 cART and 18 cART+). 31 had baseline CSF sampling (14 cART and 17 cART+) and 27 at week 24 (13 cART and 14 cART+). Increased NAA in PG (p=.03), FW (p=.005), and FG (p=.04) was observed over 24 weeks and decreased CHO in BG (p=.0005), but no differences were observed by arm. Mean cytokine levels declined in nearly all subjects. Baseline cytokine levels were associated with degree of change in each measure; however, treatment arm was not.

Conclusions: Intensification of cART with CCR5 and integrase inhibitors was not associated with differences in CSF cytokines or MRS markers of inflammation during acute HIV. Improved CNS markers of increased NAA, decreased ICHO and decreased inflammatory cytokines were noted in both groups, regardless of intensification.

HAND in Aging Populations

448 The Effects of Age and Study Cohort On Brain Structure Among Men With HIV Disease
James T. Becker1, Lawrence A. Kingsley2, Mikhail Popov2, Nisha Shah4, Andrew J. Levine4, Eileen M. Martin5, Cynthia A. Munro6, Ann Ragin7, Ned Sacktor8
1Psychiatry, Neurology and Psychology, University of Pittsburgh, Pittsburgh, PA, United States, 2Psychiatry, University of Pittsburgh, Pittsburgh, PA, United States, 3Psychiatry, University of Pittsburgh, Pittsburgh, PA, United States, 4Infectious Diseases and Microbiology, Epidemiology, University of Pittsburgh, Pittsburgh, PA, United States, 5Epidemiology, The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, 6Neurology, University of California Los Angeles, Los Angeles, CA, United States, 7Psychiatry, Rush University School of Medicine, Chicago, IL, United States, 8Psychiatry, University of California Los Angeles, Los Angeles, CA, United States, 9Psychiatry, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, 10Radiology, Northwestern University, Evanston, IL, United States

Background: Chronic HIV infection and advancing age are associated with decreased brain volume. However, as the HIV epidemic has changed since the introduction of combination antiretroviral therapy (CART), it is important to evaluate the effects of calendar period cohort recruitment on these relationships.

Methodology: 328 men (age: 50-75) enrolled in the MRI study of the Multicenter AIDS Cohort Study (MACS) underwent high resolution anatomical brain imaging (MP-RAGE at 3T field strength). The brain images from 281 met QC standards and were processed using a non-parametric correction of intensity non-uniformity (NI). Standard voxel-based morphometry (VBM) methods were run using Statistical Parametric Mapping (SPM5). Brains were segmented into grey matter, white matter and CSF compartments. The voxel-level analysis controlled for total intracranial volume and for MACS site.
Results: At the whole brain level, the HIV-infected men had significantly lower grey matter volumes (adjusted for intra-cranial volume) compared to the uninfected men (beta = -.16). Age was significantly associated with decreased grey matter volume (beta = -.20); there was no HIV-by-Age interaction. Figure 1 shows the VBM results projected onto the standard Colin27 template. The significant brain regions are shown with the t-statistics, thresholded at a False Discovery Rate of \( p < .05 \) (100 voxel extent threshold). Age was significantly associated with decreased brain volume across both cortical and subcortical regions (yellow areas in Fig. 1), including the caudate nucleus, ventral putamen, and the insular cortex. HIV disease was associated with atrophy in the basal ganglia, especially the putamen (marked in blue). The men who enrolled in the MACS in 2001/2003 had decreased brain volume in the anterior cingulate gyrus (red) relative to men who enrolled in the mid-late 1980s. There was no interaction between HIV Disease and cohort, and there was no interaction between Age and HIV Disease.

Conclusions: Although there are significant differences in brain volumes based on calendar period recruitment cohort, these effects did not interact with HIV serostatus. Within this study sample, the effects of age on brain volumes are more extensive than those associated with HIV Disease, suggesting that with survival to older age, more attention needs to be paid among infected individuals to age-associated risks for brain tissue loss.

449 FMRI Reveals Asymptomatic Deficits Among HIV+ Older Adults On cART When Compared To HIV- Controls

Manya Magnus¹, Rebecca Barasky¹, Halli Olsen¹, Xiong Jiang¹
¹Epidemiology and Biostatistics, George Washington University, Washington, DC, United States, ²Georgetown University, Washington, DC, United States

Background: Despite increased use of combination antiretroviral therapy (cART), HIV-associated neurocognitive disorders (HAND) remain prevalent among HIV+ persons, resulting in deficits among high-level executive function. The purpose of this study was to characterize neural bases of cognitive control deficits among older virally suppressed HIV+ cases vs. HIV- controls, using functional magnetic resonance imaging (fMRI). Findings will inform whether HAND processes continue in the presence of successful cART treatment and in the absence of clinical manifestations.

Methodology: HIV+ adults receiving cART with an undetectable viral load were compared with controls. Subjects were \( \geq 50 \), with no illicit drug use or contraindications to fMRI, and MMSE \( \geq 25 \). High-level executive functions were assessed with Trail Making Tests and Wisconsin Card Sorting Test. fMRI data were collected with a face-gender or word-semantic task on overlapping face and word stimuli, and a task switching paradigm where subjects were cued to respond to faces while ignoring words, or vice versa, in an unpredictable order. The cost of task switching was measured as the difference between the switch trials (first trials after task switching cue) and the repeated trials (after switch).

Results: 15 subjects completed fMRI (10 HIV+; 5 HIV-). While there were weak trends in behavior decrement among HIV+ (\( p>0.2 \)), no significant differences were found between groups for demographic, behavioral, or neurocognitive characteristics. Whole brain fMRI analysis revealed an increase in activity associated with task switching in a dorsal-anterior cluster (anterior cingulate cortex, ACC) in HIV+ (cluster size = 795, \( q_{\alpha < 0.05} \)), suggesting an increase in switching cost. Regions of interest (ROI) analysis confirmed the difference in bilateral ACC (\( p<0.01 \), but neither middle nor posterior cingulate, \( p>0.2 \)), and revealed stronger neural responses to task-irrelevant stimuli at corresponding sensory cortices in HIV+ (\( p<0.04 \)), suggesting an impairment in inhibition.

Conclusions: In HIV+ subjects without cognitive control deficits at a behavioral level, fMRI revealed significant increases in activity at executive circuits due to task switching relative to HIV- controls and impairment in inhibiting task-irrelevant information at posterior sensory cortex. Findings were present despite viral suppression, suggesting an early pathological change at a neuronal level, which may be the root of cognitive control deficits related to subsequent HAND. This pilot study informs use of fMRI as a means of predicting HAND, suggesting that viral suppression may not be sufficient to prevent HAND.

450 Longitudinal Progression of Cortical Atrophy in HIV-Patients On Stable Treatment

Michael R. Nowak¹, Bradford Navia², Jaroslav Harezlak³, Constantin Yiamoutsos⁴, Charles Gutmman⁵, Elyse Singer⁶, Thomas Campbell⁷, Eric Daar⁷, Giovanni Schifitto⁸, David Tate⁹
¹Department of Computer Science and Engineering, Texas A&M University, College Station, TX, United States, ²Tufts University Medical School, Boston, MA, United States, ³Indiana University School of Medicine, Indianapolis, IN, United States, ⁴Brigham and Women’s Hospital, Boston, MA, United States, ⁵University of California Los Angeles, Los Angeles, CA, United States, ⁶University of Colorado, Denver, CO, United States, ⁷University of Rochester Medical Center, Rochester, NY, United States, ⁸HJF for the Advancement of Military Medicine, San Antonio, TX, United States

Background: Emerging evidence largely based on cross sectional studies show that chronically infected HIV patients on effective combined antiretroviral therapy are susceptible to neuronal damage, which can lead to cognitive dysfunction. A low nadir CD4 has been shown to be an important predictor. This study examines the longitudinal progression of cortical atrophy in a representative cohort of HIV-positive patients on stable medication regimens.

Methodology: Magnetic resonance imaging (MRI) data and relevant clinical variables were obtained from the NIH-funded HIV Neuroimaging Consortium (HIVNC) cohort, for a small subsample of 18 HIV-infected patients, across three time-points (initial scan, six-month, one-year). To extract cortical thickness values evaluations, MRI data was processed using the longitudinal stream in FreeSurfer v.5.1.1 (Martinos Institute, Boston, MA). Parametric heat maps indicating clusters of significant change were calculated and used to visualize the relationship between cortical change and key baseline clinical variables.

Results: The means (SD) were: age, 48.4 (6.4) years; nadir cd4 count, 32.8 (24.6) cells/mm3; baseline cd4 levels, 319.8 (179.5) cells/mm3; duration HIV, 11.6 (7.7) years; and all on stable cART. Statistically significant (\( P < 0.05 \)) regions of cortical thinning were found over time (fig 1a), which was strongly correlated with nadir CD4 concentrations (fig 1b). Cortical thinning spans a variety of brain regions corresponding to functional systems and appears to be more focused in the primary cortical rather than association regions.
Conclusions: This is among the first studies to show that stably treated HIV-infected patients show progressive cortical atrophy, in part related to the nadir CD4 count. Further analysis is underway to assess the generalizability and functional relevance of these findings and determine the factors that contribute to brain tissue loss in the setting of stable and chronic disease.
Factors Related to Brain Atrophy in a Cohort of HIV Infected Patients: ANRS C03 Aquitaine Cohort

Carole Dufouil1, Laura Richert1, Rodolphe Thébault1, Mathias Bruguière1, Frédéric Dauchy2, Michèle Allard3, Didier Neau2, François Dabis2, Geneviève Chêne2

1HIV and associated disease team, INSERM Centre 897, Bordeaux, France, 2Services de Maladies Infectieuses et Tropicales, Bordeaux Hospital, Bordeaux, France, 3Bordeaux Hospital, Bordeaux, France

Background: Neuroimaging studies in HIV-infected patients have suggested that volume loss in cerebral white (WM) and grey matter (GM) could be associated with cognitive deficits and motor function impairment. Factors that could contribute to such structural brain abnormalities have rarely been investigated, especially in the setting of combination antiretroviral therapy (cART). In this study, we examined if HIV infection characteristics, comorbidities, cardiovascular (CV) risk factors and socio-demographic variables were independently associated with markers of cerebral atrophy in a large cohort of HIV-infected patients.

Methodology: The ANRS C03 Aquitaine Cohort recruits patients with HIV-1 infection through a hospital-based information system in southwestern France. Between 2007 and 2009, 180 participants were included in the COGLOC substudy and had a cerebral Magnetic Resonance Imaging examination in the Bordeaux University Hospital. A Voxel-Based Morphometry procedure was used to extract GM and WM volumes for each subject. Markers of cerebral atrophy were GM volumes and brain parenchymal fraction (BPF=[GM+WM]/Total Intracranial Volume). The independent association between each of the atrophy markers and age, gender, level of education, HIV characteristics, comorbidities, and CV risk factors were analyzed by covariance models.

Results: Participants’ mean age was 48.7 years, and 86% were male. Older age, longer time since HIV diagnosis, neuroAIDS condition, HIV transmission by intravenous drug use, and hypertension were independently associated with larger brain atrophy i.e reduced BPF and GM volume (Table). Neither CD4 count nor HIV RNA level was associated with cerebral atrophy severity. The results were consistent across brain atrophy markers, except for level of education: higher education being associated with larger GM, but not with BPF.

Conclusions: In HIV-infected patients, like in the general population, age is an important correlate of brain atrophy level. In addition, time since HIV diagnosis, HIV transmission by intravenous drug use, neuroAIDS stage and hypertension independently affected brain atrophy level. Future studies are needed including both longitudinal MRI and neurocognitive assessment firstly to explore whether some structural brain MRI changes are transient and secondly to investigate the mechanisms underlying brain changes in HIV infection and their functional consequences.
Multivariable analysis of factors associated with brain MRI atrophy markers

453 Hyperphosphorylated Tau in Cerebrospinal Fluid: A Biomarker for Neurological Aging in HIV-1?
Jan J. Krut1, Magnus Gisslén1, Lars Hagberg1, Henrik Zetterberg1, Richard W. Price1, Staffan Nilsson4, Paola Cinque1
1Infectious Diseases, Sahlgrenska Academy, Gothenburg, Sweden, 2Psychiatry and Neurochemistry, Institute of Neuroscience and Physiology, University of Gothenburg, Gothenburg, Sweden, 3Neurology, University of California San Francisco, San Francisco, CA, United States, 4Mathematical Sciences, Chalmers University of Technology, Gothenburg, Sweden, 5Infectious Diseases, San Raffaele Hospital, Milan, Italy

Background: With widespread use of combined antiretroviral treatment (cART), overt HIV-1 associated dementia (HAD) is rarely seen. However, milder forms of HIV-associated neurocognitive disorders have frequently been reported also in patients on cART. Hyperphosphorylated tau in CSF (p-tau) is an established biomarker in diagnosis of Alzheimer disease. It increases with age also in healthy subjects and is not influenced by neuroinflammation. In this study we decided to assess whether p-tau can be used as a marker of neurological aging in HIV patients.

Methodology: In a cross-sectional retrospective study, CSF concentrations of p-tau (phosphorylated at threonine 181) were measured with an enzyme-linked immunoassay in HIV-1 infected neuroasymptomatic patients without treatment (n=172), in HIV-infected patients on cART and plasma HIV-RNA <50 copies/ml (n=68), in HAD (n=33) and in HIV-negative controls (n=291). For statistical measures, correlations and linear regression were used.

Results: The cART group and HIV-negative controls showed significant positive correlations of p-tau and age (p<0.01 and p<0.001 respectively), whereas no significant correlations were found in the NA and HAD groups. When looking at the HIV-positive population as a whole, a significant difference was seen in slope compared to controls (p<0.001).

Conclusions: HIV-negative controls and HIV-infected on cART show significant increases of p-tau with age. No such connection could be found in untreated neuroasymptomatics and HAD. Patients with HAD do not have higher p-tau levels than asymptomatic subjects. Several younger untreated HIV-infected subjects, both asymptomatic and with HAD, had high p-tau while this is not the case in older individuals. The mechanism behind this skewness remains to be explained.
Corneal Sensory Nerve Fiber Loss in SIV-Infected Macaques: Tracking HIV PNS Damage

Jamie Dorsey, Lisa Mangus, Jonathan Oakley, Joseph Mankowski

Background: Human immunodeficiency virus-associated peripheral neuropathy (HIV-PN) is currently the most frequent neurologic complication of HIV infection, affecting most individuals living with HIV. HIV-PN is a length-dependent small sensory fiber neuropathy typified by bilateral numbness, tingling, and burning sensations in the lower legs. Because electrophysiology is insensitive to changes in small unmyelinated fibers, microscopic evaluation of epidermal nerve fiber density in skin biopsies has become the standard for diagnosis of HIV-PN. However, longitudinal assessment is limited by the invasiveness and technical demands of this technique. While noninvasive assessment of corneal sensory nerves has proven clinically useful in diagnosing and monitoring other peripheral neuropathic conditions, such as diabetic neuropathy, corneal nerve alterations in HIV have yet to be characterized.

Methodology: To determine whether corneal nerve alterations developed in an SIV model of HIV-PN, we established a βIII tubulin immunostaining protocol for detecting nerves in corneal whole mount specimens harvested at terminal timepoints, and then developed novel manual and automated counting methods to measure corneal nerve density.

Results: Manual and automated counting methods each demonstrated significantly lower subbasal corneal nerve fiber counts among SIV-infected animals that rapidly progressed to AIDS as compared to slow progressors. Concomitant with decreased corneal nerve fiber density, rapid progressors had increased levels of SIV RNA, CD68-positive macrophages, and GFAP expression by glial satellite cells in the trigeminal ganglia (P<0.05, Mann-Whitney).

Conclusions: These findings demonstrate that corneal nerve assessment has great potential to diagnose and monitor HIV-induced peripheral neuropathy. In particular, noninvasive techniques such as in vivo corneal confocal microscopy may be valuable to identify and track PNS damage in the HIV clinical setting.

Efavirenz Produces a Differential Bioenergetic Response in Neurons and Glial Cells

Haryes A. Funes, Nadezda Apostolova, Fernando Alegre, Miriam Polo, Ana Blas-Garcia, Juan V. Esplugues

Background: CNS side effects are the main adverse events of Efavirenz (EFV), but the mechanisms responsible are unknown although recent evidence shows that this drug undermines mitochondrial function. Neurological pathogenesis is often associated with mitochondrial dysfunction and it is known that glia cells overcome the damaging effects of mitochondrial inhibition by rapidly up-regulating AMP-kinase (AMPK)-mediated glycolysis and maintaining ATP levels, which is crucial for cell homeostasis and viability. In contrast, neurons lack this defence mechanism, which makes them more vulnerable to bioenergetic challenge. We have analysed if EFV interferes with the mitochondria of neurons and glia cells and assessed its influence on cellular bioenergetics. Since there is a substrate of CNS inflammation during HIV-related cognitive disorders, we have also evaluated if EFV effects are exacerbated by nitric oxide (NO), a mediator of inflammation and inhibitor of mitochondrial respiration.

Methodology: Human cell lines (glioma and neuroblastoma) and rat primary cultures of astrocytes and neurons were treated with clinically relevant concentrations of EFV. Exogenous NO was applied by addition of its donor DETA-NO. Parameters of mitochondrial function and bioenergetics were studied using standard cell biology techniques. Data (mean±S.E.M, n=3-5) were expressed as % (of untreated cells, considered 100%) and analysed by Student’s t-test, significance vs. vehicle.

Results: EFV (10 and 25 μM) inhibited mitochondrial respiration, enhanced ROS generation, undermined Δψm and reduced ATP levels in a significant and concentration-dependent fashion in both neurons and glia. However, AMPK was activated only in glia, leading to an up-regulation of glycolysis (enhanced lactate production and increased intracellular ATP), whereas in neurons there was a decrease in ATP concentration. The combination of EFV+NO potentiated the effects of either one on mitochondrial parameters in both neurons and glia, but ATP generation and lactate production were again enhanced only in the latter. EFV+NO did not deplete the number of glia (Veh=103.1±1.831; EFV10=103.3±2.078; DETA-NO=74.43±1.645***; DETA-NO+EFV10=69.86±2.703***), but substantially aggravated the effect of EFV (10μM) on neurons (Veh=103.2±1.372; EFV10=96.38±2.761*; DETA-NO=65.00±4.359***; DETA-NO+EFV10=27.80±3.666***) (% of untreated cells).

Conclusions: Our results suggest that EFV exerts a direct and specific effect on the energetic balance and viability of neurons and glia through a mechanism involving acute mitochondrial inhibition, an action that could be exacerbated in neuroinflammatory conditions like those often present in HIV-patients, or when the brain-blood-barrier is disrupted.
**456 HIV-Tat Protein in Inflammatory Infiltrates of CNS-IRIS and in CSF of Patients On ART**
Gloria von Geldern1, Tony P. Johnson1, Richa Tyagi1, Ned Saciktor1, Justin C. McArthur1, Scott Letendre1, Avindra Nath1
1NINDS, NIH, Bethesda, MD, United States; 2Dept. of Neurology, Johns Hopkins University, Baltimore, MD, United States; 3Dept. of Neurology, Johns Hopkins University, Baltimore, MD, United States; 4Dept. of Neurology, University of California, San Diego, San Diego, CA, United States

**Background:** Persistent low level inflammation is found in most patients with chronic human immunodeficiency virus (HIV) infection despite virological control on antiretroviral therapy (ART). Some of these individuals develop immune reconstitution inflammatory syndrome of the central nervous system (CNS-IRIS), the pathophysiology of which is poorly understood.

**Methodology:** We immunostained brain biopsy and autopsy tissue and from HIV infected individuals on ART with CNS-IRIS, from virologically controlled HIV infected without IRIS as well as from patients with HIV encephalitis (HIVE). Tissue was stained for the HIV-proteins transactivator of transcription (Tat) and p24 antigen as well as for T cell markers. We established an ELISA for the detection of Tat and examined in the cerebrospinal fluid (CSF) of HIV patients on ART (n=65).

**Results:** Brains from patients with CNS-IRIS showed monocytic infiltrates which strongly stained for Tat while p24 immunostaining was negative. Tat was also present in 2/7 HIV patients on ART without evidence of p24. HIV brain tissue demonstrated Tat and p24 expressing macrophages in microglial nodules and perivascular regions. In the CNS-IRIS patients, infiltrates consisted of CD3+ T-cells which were predominantly CD8+ with few CD4+ cells and occasional IL-17+ cells. In 32/65 CSF samples of HIV-infected individuals on ART, Tat was detected by ELISA. In a subset of CSF samples the presence of Tat was confirmed by Western blot analysis.

**Conclusions:** HIV-Tat protein may drive inflammation in the form of acute CNS-IRIS or chronic inflammation in the CSF of individuals controlled on ART. While ART controls HIV replication it fails to impact Tat production. The prevention of Tat production is therefore an important therapeutic target.

**457 Central Nervous System Demyelination in Pediatric SIV Infection**
Herman Kamboj1, Kimberly Curtis1, Heather Carry1, Hayford Agymang1, Koen Van Rompay2, Kristina Abel3, Mark Burke3
1Physiology & Biophysics, Howard University, Washington, DC, United States; 2University of California Davis, Davis, CA, United States; 3University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

**Background:** Pediatric HIV infection remains a global health crisis with an estimated 1,500 children under the age of 15 years becoming infected with HIV-1 each day in the developing world. Children are much more susceptible to HIV-1 neurological impairments than adults. Imaging studies have shown reduced radial diffusivity, suggesting demyelination may be a prominent feature in pediatric HIV infection that is associated with diminished executive function. A major obstacle in pediatric HIV research is sample access. The proposed studies take advantage of ongoing pediatric SIV pathogenesis and vaccine studies to test the hypothesis that pediatric SIV infection diminishes myelinated fibers in the frontal and motor cortices as well as the hippocampus.

**Methodology:** Newborn rhesus macaques (Macaca mulatta) that received oral inoculation with a repeated-exposure of SIVmac251 (n=4) or vehicle (control n=4) were recruited for this study. After a 6-18 week survival time, the animals were sacrificed and the brains prepared for quantitative histopathological analysis. Matched sections from the frontal cortex, motor cortex and hippocampus were stained with gold chloride, a putative marker for myelin.

**Results:** We report here a significant reduction in myelination and myelinated fibers in the frontal cortex, motor cortex, and hippocampus.

**Conclusions:** Previously reported from this model has shown significant loss of hippocampal neurons and neurogenic capacity that may contribute to the rapid neurocognitive decline associated with pediatric HIV infection. Data presented here that neuronal loss may be exacerbated by loss of central nervous system myelination. These data provide a neuroanatomical substrate for reduced radial diffusivity as well as reported multiple sclerosis-like signs in HIV-1 infected children. Support: U.S. PHS grants S06GM08016 (MBRS-SCORE, NIGMS/NIH) to TH; Leadership Alliance Fellow to MR; District of Columbia Developmental Center for AIDS Research (P30AI087714) to MB; and 1R01DE019064 (NIH/NIDCR) and 2P30 AI050410 to KA.

**458 Brain Iron Transport Is Associated With Neurocognitive Performance in HIV/AIDS**
Asha R. Kallianpur1, James R. Connor2, Christopher C. Coo1, Benjamin B. Gelman1
1Genomic Medicine, Cleveland Clinic Foundation/Lerner Research Institute, Cleveland, OH, United States; 2Neurosurgery, Penn State Milton S. Hershey Medical Center, Hershey, PA, United States; 3Psychology, University of Wisconsin, Madison, WI, United States; 4Pathology, University of Texas Medical Branch, Galveston, TX, United States

**Background:** Iron dysregulation in the brain is a consistent and poorly understood feature of neurocognitive disorders, and functional neuronal iron deficiency has been implicated in certain dementias. We hypothesized that HIV-Associated Neurocognitive Disorder (HAND) pathophysiology involves brain iron deficiency, reflected by increased transferrin receptor (TFR) RNA expression in brain.

**Methodology:** Subjects who died of HIV/AIDS and participated in the National NeuroAIDS Tissue Consortium (NNTC) Study underwent uniform autopsy/neuropathology protocols and comprehensive neurocognitive assessments within 6 months post-mortem. HAND was defined according to the Frascati criteria. Total RNA was extracted and purified from frozen brain tissue (frontal neocortex at Brodmann Area 9); TFR messenger RNA was quantified by RT-PCR. Associations of TFR RNA expression with HAND and standardized, neurocognitive domain scores were assessed by multivariable-adjusted regression analysis to estimate β-coefficients (β) or odds ratios (OR) and their 95% confidence intervals (CI).
Results: Among 287 evaluated decedents from the NNTC Brain Bank (mean age 44, median CD4 cell count 109/mm³, 31% pre-HAART era), HAND was present in 243 (85%), including asymptomatic neurocognitive impairment (N=76), mild neurocognitive disorder (N=72), and dementia (N=95). TFR RNA expression levels, available in 274 subjects (91%), were unrelated to brain viral burden. TFR RNA expression in neocortex was associated with HAND (crude OR 2.3, p<0.05 for all diagnoses combined; OR 2.9, p<0.01 for association with dementia) in unadjusted analyses; TFR RNA levels were 15.4% higher in HAND cases than controls [median 0.90 vs. 0.78, respectively (p=0.05)]. These associations persisted after adjustment for age at neurocognitive testing, race/ethnicity, plasma CD4 cell count, total RNA, post-mortem interval, hepatitis C co-infection, and current/past alcohol abuse [OR 5.2 (95% CI 1.5-18.1, p<0.05) for all HAND; OR 5.9 (95% CI 1.6-22.3, p<0.05) for asymptomatic and mild neurocognitive impairment combined; OR 7.7 (95% CI 1.3-45.6, p<0.05) for dementia]. Speed of information processing, attention working memory, and global T-scores were or tended to be negatively associated with TFR RNA expression [adjusted β = -3.4 and -3.0 for speed of information processing and attention working memory, respectively (both p<0.05); adjusted β = -2.6 for global T-score (p=0.07)].

Conclusions: TFR RNA expression in the frontal neocortex is independently associated with both milder and more severe forms of HAND and with performance on neurocognitive testing among individuals dying of HIV/AIDS, suggesting a role for brain iron deficiency in HAND etiology and/or progression.

460 HIV-Associated Neurocognitive Disorders Display a Distinct MicroRNA Profile in Plasma
Eugene L. Asahchop, David Broadhurst, John Gill, Christopher Power
1Medicine, University of Alberta, Edmonton, AB, Canada; 2Medicine, University of Calgary, Calgary, AB, Canada

Background: Despite successful antiretroviral therapy, ~20% of HIV-infected patients still progress to develop HIV-associated neurocognitive disorders (HAND). HAND is a multifactorial process that is influenced by both viral and host gene expression, host immune responses, as well as highly active antiretroviral therapy. Host-encoded microRNAs represent a potent mechanism by which both host (and viral) genes are regulated. Thus, comprehensive profiling of microRNAs could yield potential insights into underlying disease mechanisms. Recent studies have reported that microRNA (miRNA) profiles differ between HIV-infected individuals with and without HAND in brain and also in blood between elite controllers versus viremic HIV/AIDS patients. These findings prompted us to examine plasma microRNA expression in HIV/AIDS patient with and without symptomatic HAND.

Methodology: Cell-free total RNA was isolated from archived plasma specimens collected from HAND (n=14) and nonHAND (n=14) patients with HIV/AIDS in active care with consent. Total RNA was labeled followed by array hybridization. Data were normalized, subjected to quality control assessment, summarized using expression console software and differentially expressed miRNAs were identified subsequently. Computational analyses utilizing existing microRNA databases and bioinformatics programs (miRDB, miRBase), permitted data analyses including nonparametric univariate analyses (Mann Whitney U tests and Spearman correlation).

Results: Each array identified ~5600 miRNAs per plasma sample for all study subjects (n=28). Analysis of comparative abundance identified 17 miRNAs that were highly expressed (p &lt 0.05) with a fold change (FC) of greater than 2 in the HAND group compared to the nonHAND group but no miRNAs were comparatively repressed in HAND patients. Additionally, seven differentially expressed miRNAs (FC &gt 2.5) were correlated with both age and CD4 T cell count (at the time of sampling) (p &lt 0.05). In subsequent analyses in which patients were grouped as HAND and CD4 &lt 200 or nonHAND and CD4 &gt 200, 16 miRNAs were up regulated in the HAND and CD4 &lt 200 group; 9 of 16 miRNAs in this latter analysis were in agreement with the HAND versus nonHAND analysis. Bioinformatics analyses of induced microRNAs in plasma from HAND patients showed that predicted target genes included those involved in brain development, survival of neurons and astrocyes as well as inflammation.

Conclusions: These findings indicate that cell free miRNAs in plasma are differentially expressed in HAND versus nonHAND patients but were also associated with concurrent age and immune status. Furthermore, plasma miRNAs might be used as future biomarkers of disease progression including the development of symptomatic HAND.

461 Cognitive and Brain Microstructure Abnormalities in HIV-1 Infected Humanized Mice
1Pharmacology and Exp. Neuroscience, University of Nebraska Medical Center, Omaha, NE, United States; 2Radiology, University of Nebraska Medical Center, Omaha, NE, United States; 3University of Rochester Medical Center, NY, NY, United States

Background: We reported modest neuropathological change that follows progressive HIV-1 infection of humanized mice. Whether such changes are relevant to human disease including cognition and behavior are not known. To these ends, we applied time-dependent behavioral and advanced neuroimaging tests to infected animals to assess relationships between immune and cognitive function, viral replication and brain metabolites to HIV-1-associated neuropathology.

Methodology: Humanized NOD/scid-IL-2Rgcnull mice transplanted at birth with human CD34+ hematopoietic stem cells were infected with HIV-1ADA at 22 weeks of age. Infection was followed for 16 weeks. Mice were bled at 0, 4, 8, 12 and 16 weeks post-infection (wpi) for human immune cell analysis by flow cytometry and viral load (VL) measurements. Animals were subjected to serial volume selective proton magnetic resonance spectroscopy (1H MRS) and diffusion tensor imaging (DTI) at pre- and 4, 8, 12, and 16 wpi to measure brain metabolites and changes in tissue architecture, respectively. Total RNA from cortex was isolated at the study end from both infected and control mice groups and HIV-1gag was quantified using real-time quantitative PCR to look at the brain viral RNA level. Animals were evaluated one week prior to and 4 and 8 weeks following viral infection by open field activity (OFA) test as a measure of habituation in new environments, motor function and field exploratory behavior. At the study end, brains were analyzed immunohistochemically for neuronal, oligodendrocytes and glial inflammatory markers.
Results: Mice showed sustained plasma viremia with concomitant reductions in CD4+ T lymphocytes. Behavioral abnormalities included failure to habituate to a new environment and increased anxiety with HIV-1 infection. Systemic viral loads were associated with selective cortical N-acetyl aspartate, creatine and choline reductions. Diffusion tensor imaging (DTI) abnormalities were detected in white matter fiber structure and in cortical gray matter in HIV-1 infected animals compared to uninfected controls. Post-mortem multispectral imaging microscopic analysis of brain tissue showed reduction in synaptophysin, neurofilament and glial antigens, those are reflective of DTI and metabolite changes.

Conclusions: These results demonstrate, for the first time, notable relationships between viral load, imaging abnormalities and brain region-specific neurodegeneration in a mouse model demonstrating neurocognitive deficits. These findings are clearly reflective of human disease and can be applied to future therapeutic interventions for neuroAIDS.

462 SIV Dynamics in the CD8-Depleted vs Non-CD8-Depleted Rhesus Macaque Model for NeuroAIDS
Susanna L. Lamers1, David J. Nolan2, Brittany D. Rife1, Gary B. Fogel1, Tricia Burdo1, Kenneth C. Williams1, Marco Salmen1
1Bioanalytics, LLC, Thibodaux, LA, United States, 2Department of Pathology, Immunology, and Laboratory Medicine, University of Florida, Gainesville, FL, United States, 3University of Florida, Gainesville, FL, United States, 4Natural Selection, San Diego, CA, United States, 5Boston College, Boston, MA, United States

Background: Appropriate animal models are required to understand why neurological disease due to HIV infection persists in the era of cART. The CD8-depleted and SIV-infected macaque is frequently used to study the pathogenesis of HIV because it results in the rapid onset of SIV-associated encephalitis, which ensures the collection of a large amount of data for researchers in a short period of time, while reducing animal suffering and maintenance costs. Of interest is how CD8 depletion may generate a biological environment that may or may not impact viral evolution in nature.

Methodology: Two groups of macaques were inoculated with the SIVmac251 viral swarm. One group of six macaques, was CD8-depleted, while another group of 12 macaques, was allowed to progress naturally with SIV. At three weeks post infection, SIV envelope sequences were generated from tissues (plasma, CD14, and bronchial lavage) from all macaques. Two hundred viral swarm sequences were generated for comparison to the macaque data. Evolutionary analyses, including clustering, phylogeny, recombination, selection and signature pattern analysis were performed for the 3-week sequence data. Virus was also quantitated from tissues at the time of euthanization, including brain, for all CD8-depleted macaques and 7 of the non-depleted macaques (at this time five macaques have not been euthanized).

Results: Viral diversity in both groups of macaques was similar and significantly increased when compared to the viral swarm. Clustering analysis showed considerable overlap between the CD8-depleted and non-CD8-depleted macaque sequences; however, potentially macrophage tropic SIV, with signatures associated with brain were found only in the CD8-depleted macaques. Positively selected sites between the two groups of macaques were also similar and frequently mapped to putative recombination breakpoints. At end-stage disease, virus was isolated from all tissues in the CD8-depleted macaques; however, 5 out of 7 of the non-depleted macaques did not have any amplifiable SIV RNA or DNA in brain and bone marrow tissue samples while maintaining high viral loads in CD14+ and CD3+ cells until death.

Conclusions: In terms of sequence evolution, the primary difference between the two groups of macaques was the emergence of a small number of potentially neurotropic virus in the CD8 depleted animals, which is interesting since all CD8-depleted macaques developed neuroAIDS, while only 1 in 12 non-depleted macaques have developed neuroAIDS at this time. The finding that low viral load levels in bone marrow and brain coincide with the lack of encephalopathy may implicate bone marrow as the source of brain virus. The study supports research using the CD8-depleted, rapidly-progressing macaque model for the study of neuroAIDS.

463 Vascular Endothelium and Neurological Performance During Primary HIV Infection
Sebastian Urday1, Kevin Robertson1, Fang-yong Li2, Felicia C. Chow1, Julia Peterson1, Elaine M. Nitta1, Richard W. Price1, Priscilla Y. Hue1, Serena Spudich1
1Yale University, New Haven, CT, United States, 2University of North Carolina, Chapel Hill, NC, United States, 3University of California, San Francisco, San Francisco, CA, United States

Background: HIV-infected individuals with well-controlled infection have increased rates of premature cardiovascular (CV) disease and neurocognitive dysfunction. In longstanding HIV infection, vascular disease and neurological dysfunction may associate, connected through a common pathogenetic pathway of inflammation, which persists even in the setting of optimal antiretroviral therapy (ART). We tested whether measures of CV and neurologic function correlate during the early stages of HIV infection.

Methodology: 15 individuals with primary HIV infection (PHI, < 1 year since HIV transmission) underwent both CV and neurologic testing in San Francisco, USA. Vascular measures included: (1) carotid artery intima-media thickness (IMT) in the common carotid, bifurcation region and internal carotid artery; (2) brachial artery flow-mediated dilation (FMD); (3) hyperemic velocity; and (4) asymmetric dimethylarginine (ADMA), a plasma marker of endothelial dysfunction and atherosclerotic potential. Neuropsychological performance was measured as total z-score (based on normed performance on 11 tests) and frequently mapped to putative recombination breakpoints. At end-stage disease, virus was isolated from all tissues in the CD8-depleted macaques; however, 5 out of 7 of the non-depleted macaques did not have any amplifiable SIV RNA or DNA in brain and bone marrow tissue samples while maintaining high viral loads in CD14+ and CD3+ cells until death.

Results: At baseline, PHI subjects had a median age of 37 (IQR 32, 47) years, CD4 count of 474 (361, 656) cells/µL, plasma HIV RNA of 4.59 log10 copies/ml (3.64, 4.94), and CSF HIV RNA of 2.58 log10 copies/ml (1.69, 3.33). Subjects were enrolled at median 93 (77, 153) days post infection and 100% were ART naïve. The interval between CV and neurologic testing was 31 (16, 75) days. Duration of follow-up was 364 (0, 641) days. Higher ADMA and asymmetric dimethylarginine correlated with worse neuroAIDS (P < 0.05). Unexpectedly, greater IMT in the left internal carotid artery and overall mean IMT correlated with better neuroAIDS (r = 0.73, P = 0.02; r = 0.64, P = 0.04, respectively). No associations were found between FMD or hyperemic velocity and neurologic measures.
Conclusions: In an exploratory analysis, higher ADMA levels, suggestive of more severe endothelial dysfunction, inversely correlated with neuropsychological performance during early HIV infection. A seemingly paradoxical association between increased IMT, another surrogate marker of atherosclerosis, and better neuropsychological performance warrants further study.

Session P-G4 Poster Session

Host Genetics in HAND

464  **Heme Oxygenase-1 Polymorphism and Protein Deficiency Associated With Neurological Disease in HIV**

**Alexander J. Gill**, Suren S. Ambegaokaar, Colleen E. Kovacsics, Stephanie A. Cross, Benjamin B. Gelmann, Dennis L. Kolson

1Department of Neurology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, United States, 2Department of Pathology, University of Texas Medical Branch, Galveston, TX, United States

**Background:** Neuroprotective therapies that target the pathological processes persisting in ART-treated individuals are needed. Heme oxygenase-1 (HO-1) has anti-inflammatory and neuroprotective roles and was recently proposed to modulate the association between inflammation and HIV replication in HIV-infected individuals. HIV infection of monocyte-derived macrophages (MDM) reduces HO-1 protein expression and pharmacologic rescue of HO-1 expression ameliorates HIV-MDM neurotoxicity production. We have now investigated the role of HO-1 in neuroinflammation and neurocognitive impairment in HIV-infected individuals.

**Methodology:** Protein and RNA expression were analyzed by Western blot and qPCR, respectively, in prefrontal cortex lysates from HIV-, HIV+, and HIV encephalitis (HIVE) brains (n=156) from clinically characterized subjects from the National NeuroAIDS Tissue Consortium. HO-1 promoter regions were genotyped by PCR with capillary electrophoresis. Statistical analysis was performed by ANOVA with a Holm-Sidak post-test and multivariate linear regression.

**Results:** HO-1 protein levels were deficient in the prefrontal cortex of HIV+ subjects compared to HIV- controls (p<0.01), with more severe HO-1 deficiency observed in HIV subjects (p<0.001). HO-1 deficiency correlated with CNS viral load and with brain parenchymal markers of macrophage and innate immune activation (CD163, ISG15, MX1). HO-1 deficiency correlated with neurocognitive impairment in executive and speed of processing domains in the Caucasian subpopulation (p<0.01). Prefrontal cortex HO-1 RNA was elevated in HIV subjects (p<0.01), suggesting a post-transcriptionally mediated deficiency. Shorter variants of a HO-1 promoter region GT(n) microsatellite polymorphism, previously shown to associate with enhanced HO-1 transcription, correlated with increased HO-1 protein expression and decreased mRNA expression of markers of macrophage activation (CD163, CD68) in the prefrontal cortex. Moreover, shorter HO-1 promoter variants were associated with a significantly lower prevalence of HIV among HIV+ subjects (p<0.05).

**Conclusions:** HIV infection reduces CNS HO-1 protein expression post-transcriptionally and this deficiency may play a role in neuroinflammation and neurocognitive impairment in HAND patients. Variations in a HO-1 promoter region microsatellite polymorphism may be a genetic determinant of brain HO-1 protein production and subsequent HIV neurological disease progression. HO-1 is a potentially targetable neuroprotective host factor that modulates macrophage-mediated neurodegeneration in HIV infection. Therapeutic inducers of HO-1 need to be examined for the potential clinical efficacy in reducing the prevalence of HAND in ART-treated individuals.

465  **Mitochondrial DNA Haplogroups and Neurocognitive Impairment in the CHARTER Cohort**

**Todd Hulgan,1 David Samuelis,1 William Bush,1 Ronald Ellis,2 Scott Letendre,2 Peter Straub,1 Deborah Murdock,1 Donald Franklin,2 Igor Grant,2 Asha Kallianpur3, for the CNS HIV Antiretroviral Therapy Research (CHARTER) Group

1Vanderbilt University, Nashville, TN, United States, 2University of California San Diego, San Diego, CA, United States, 3Cleveland Clinic Foundation/Lerner Research Institute, Cleveland, OH, United States

**Background:** Neurocognitive impairment (NCI) remains an important complication of HIV infection in the combination antiretroviral therapy (CART) era. Mitochondrial DNA (mtDNA) haplogroups are ancestry-related patterns of single nucleotide polymorphisms that have been associated with neurodegenerative diseases in HIV-uninfected populations, and with HIV- and CART-associated outcomes. We hypothesized that mtDNA haplogroups are associated with NCI in HIV-infected adults, and examined these associations in CHARTER.

**Methodology:** CHARTER is a U.S.-based observational study of ambulatory HIV-infected adults who underwent standardized neurologic assessments. Primary outcomes were the global deficit score (GDS; both as a continuous measure and impairment defined as GDS≥0.5) and HIV-associated neurocognitive disorder (HAND; defined using Frascati Criteria). Haplogroups were assigned using mtDNA sequence from whole blood and HaploGrep; analyses were race/ethnicity stratified. Multivariable regression of associations between haplogroups and GDS or HAND were performed adjusting for comorbidity status (incidental vs. contributing), current CART status (yes vs. no), plasma HIV RNA, CHARTER site, wide-range achievement test score, and CD4 T cell nadir.

**Results:** Haplogroups were available from 1068 persons without confounding comorbidities; median age was 43 years, CD4 nadir was 180 cells/mm³, 763 (71%) were on CART, and 492 (46%) had HAND at baseline. In cross-sectional univariable analyses, Hispanics (N=104; 9.7%) had a greater likelihood of both GDS impairment and HAND (p<0.001 for both). Among Hispanics, those belonging to haplogroup B (N=18; 17%) had a lower median GDS (0.21 vs. 0.63; p=0.004), and lower likelihood of HAND of any severity (OR 0.30; 95% CI 0.11-0.87) and GDS impairment (OR 0.19; 0.06-0.62). These relationships persisted in stratified analyses of subgroups on CART, with detectable plasma HIV RNA, or with incidental comorbidities. There were no statistically significant differences by haplogroup among non-Hispanics. In adjusted models, haplogroup B tended to be associated with a lower GDS.
MBL2 Promoter Polymorphism rs7096206 Predicts Brain Metabolite Anomalies in HIV-Infected Adults

Kumud K. Singh, Qianqian Deng, Christine Feinerman-Notestine, Florin Vaida, Ronald J. Ellis, Scott L. Letendre, Donald Franklin, Debralee Rosario, Robert K. Heaton, Igor Grant, and CHARTER Group

University of California San Diego, La Jolla, CA, United States

Background: Mannose binding lectin, coded by MBL2 gene, recognizes high-mannose N-linked glycans on HIV-1 gp120 and activates complement pathway leading to HIV-1 opsonization and phagocytosis; however its role in HIV-related neuropathogenesis is unclear. We hypothesized that the presence of MBL2 promoter polymorphism rs7096206 (-221-G/C or MBL2-Y/X), linked to lower expression, impaired complement activation, and inflammatory cytokines response, will predict neuroinflammation and brain damage in HIV-infected adults.

Methodology: 244 subjects from the CHARTER (CNS HIV AntiRetroviral Therapy Effects Research) cohort were evaluated with single voxel magnetic resonance spectroscopy (svMRS) to assess levels of brain metabolites choline (CHO), creatine (CR), N-Acetylaspartate (NAA) and myo-inositol (MI) in frontal white matter (FWM), frontal gray matter (FGM) and basal ganglia (BG) using LC Model. GWAS MBL2-rs7096206 genotype associations with brain structural MR imaging (sMRI) volumes and svMRS were cross-sectionally examined by multi-variable linear regression. All analyses controlled for scanner and either cranial vault volume (for sMRI) or proportion of tissue in voxel (svMRS). Adjusted analyses included comorbidity, current CD4>=200, nadir CD4 nadir and other factors listed above.

Results: Of the 244 subjects studied, 81% were male; 53% White and 43% Black. MBL2-rs7096206 wild type Y/Y, heterozygote Y/X and homozygote variant X/X genotypes were present in 64%, 32% and 4% individuals respectively. 76% of 244 were on HAART and 11% were ARV naïve. The variant MBL2-X allele was associated with higher CHO in FWM (8.2% [2.3%, 14.4%], p=0.057) and BG (8.6% [3.5%, 14%], p=0.001) in the whole cohort; this was also true in the on-HAART only group (FWM: 10.9% [3.4%, 18.9%], p=0.043; BG: 9.8% [3.5%, 16.4%], p=0.025). The X allele also associated with higher CR in FWM (8.2% [3.2%, 13.4%], p=0.011) in the whole cohort; this effect remained significant in the on-HAART group in the FWM (9.1% [2.8%, 15.8%], p=0.043).

Conclusions: Higher levels of CHO in the presence of the MBL2-X allele suggest greater inflammation in the HIV-1 infected brain. Higher CR may suggest increased energy metabolism in the brain to counteract HIV-1 mediated inflammation. Presence of MBL2-X allele results in lower MBL levels, impaired innate immune response and complement activation leading to the deposition of MBL-gp120 complexes and inflammatory cytokine response resulting in neuroinflammation and brain damage. These findings suggest that MBL2 genotype is a potential predictive biomarker for HIV-related neuroinflammation and brain damage.

Pathogenesis of JC Virus Reactivation During Natalizumab Treatment

Spyridon Chalkias1, Xin Dang1, Evelyn Bord2, Marion Steir3, Philip Kirkel4, Jacob Sloan5, Maria Houckers6, Guy Buckle1, Carolina Ionete1, Igor Koralnik1

1Harvard Medical School, Center for Virology and Vaccine Research, Boston, MA, United States; 2Department of Neurology BIDMC, Boston, MA, United States; 3Department of Neurology BWH, Boston, MA, United States; 4Department of Neurology UMass, Worcester, MA, United States

Background: Progressive multifocal leukoencephalopathy (PML), caused by JC virus (JCV), is an opportunistic infection in immunocompromised hosts and its pathogenesis remains elusive. Recently, PML affects multiple sclerosis (MS) patients treated with natalizumab, a monoclonal antibody against alpha-4 integrins which prevents entry of inflammatory cells in the central nervous system. We sought to uncover the site and prevalence of JCV reactivation and determine JCV-specific cellular reaction during prolonged exposure to the drug.

Methodology: We enrolled 39 JCV-seropositive MS patients, including 32 on natalizumab monotherapy for 18-20 months (n=14), 22-25 months (n=7) and >36 months (n=11), 2 on interferon-beta monotherapy >36 months and 5 untreated MS patients as controls. We performed QPCR in CSF, blood and urine for JCV DNA and we determined JCV specific T-cell responses using enzyme-linked immunospot (ELISpot) and intracellular cytokine staining (ICS) essays, ex vivo and after in vitro stimulation with JCV peptides

Results: JCV DNA was detected in the CSF of 3/35 (8.6%) subjects tested (1 in 18-20 and 2 in >36 months on natalizumab), who had no symptoms or MRI lesions consistent with PML. JCV DNA was detected in peripheral blood mononuclear cells (PBMC) of 10/39 (25.6%) subjects but not in plasma. JCV DNA load was higher in CD34+ cells compared to B Cells (p=0.0064), T cells (p=0.0035) and polymorphonuclear (PMN) cells (p=0.0043) and in monocytes compared to T cells (p=0.0048) and PMN (p=0.008). Viruria was detected in 8/39 (20.5%) patients. JCV-specific CD4+ T-cells were detected ex vivo more frequently in subjects with JCV DNA in PBMC (p=0.027). JCV-specific T cells were detected more frequently by ICS than ELISpot ex vivo [26/39 (66.7%) vs 6/39 (15.3%);p<0.001] and after in vitro stimulation [39/39 (100%) vs 33/38 tested (86.8%);p=0.03]. Both assays were...
Impaired T. pallidum Opsonic Antibody Function in HIV-Infected Patients With Neurosyphilis

Christina Marra, Lauren Tantalo, Sharon Sahi, Emily Ho, Sheila Dunaway, Trudy Jones, Sheila Lukehart

University of Washington, Seattle, WA, United States

**Background:** Compared to HIV-uninfected (HIV-) patients, HIV-infected (HIV+) patients may be at increased risk of neurosyphilis (NS). T. pallidum, the bacterium that causes syphilis, is cleared from sites of infection by activated macrophages that engulf and kill opsonized organisms. We hypothesized that HIV+ individuals might have a defect in opsonic antibody production or function that could impair bacterial clearance and predispose them to NS.

**Methodology:** Monocyte derived macrophages (MDMs) were derived from peripheral blood mononuclear cells in culture with 1 ng/ml macrophage colony stimulating factor. MDMs were incubated with Nichols strain T. pallidum at a bacterium to cell ratio of 25:1 with 17% patient sera for 4 hrs. at 37°C in 5% CO₂, fixed and stained by immunofluorescence for T. pallidum. Opsonic capacity of sera was determined as % MDMs ingesting opsonized T. pallidum and was normalized to the result of a pool of sera from 55 HIV+ and HIV- patients with syphilis (RPR titer 1:64). Normal human AB sera served as the negative control. Mann-Whitney U test was used to compare continuous variables between groups and linear regression was used for multivariable analysis.

**Results:** Serum opsonic capacity was determined in quadruplicate for 53 HIV+ and 24 HIV- patients with syphilis. Median serum RPR titer (IQR) was significantly higher in HIV+ compared to HIV-: 1:128 [1:64-1:256] vs. 1:64 [1:32-1:128], p=0.001. 21 HIV+ and 10 HIV- had NS (reactive cerebrospinal fluid (CSF)-Venereal Disease Research Laboratory test or CSF white blood cells >20/μL). Serum opsonic capacity was higher in patients whose RPR titers were ≥1:32 compared to those with <1:32 (0.54 [0.37-0.84] vs. 0.40 [0.26-0.53], p=0.02) and in HIV- compared to HIV+ (0.62 [0.40-1.20] vs. 0.43 [0.29-0.64], p=0.01). Opsonic capacity remained significantly higher in HIV- patients after taking into account serum RPR titer (p=0.003). Among the HIV+, opsonic capacity was lower in patients with NS compared to those without NS (0.38 [0.28-0.55] vs. 0.47 [0.30-0.67], p=0.11); when serum RPR titer was taken into account, this difference was significant (p=0.047). Opsonic capacity did not differ by CD4 count or ARV use.

**Conclusions:** Despite having lower RPR titers, sera from HIV- patients with syphilis had significantly greater opsonic capacity than sera from HIV+ individuals with syphilis. Among the HIV+, those with NS had significantly lower serum opsonic capacity compared to those without NS. These results suggest that HIV+ syphilis patients may be at increased risk of NS because of impaired opsonic antibody production or function.

Significance of Plasma JCV-DNA in HIV Progressive Multifocal Leukoencephalopathy (PML)

Francesca Ferretti1, Manuela Testa1, Valeria Longo1, Constantin Theodore Yiannoutsos2, Beverly Sue Musick1, Annamaria Pazzi1, Antonio Boschinì1, Simona Bossolasco1, Adriano Lazzarini1, Paola Cinque1

1San Raffaele Scientific Institute, Milan, Italy; 2Department of Biostatistics, Indiana University, Indianapolis, IN, United States; 3S.Patrignano Medical Centre, Ospitaletto di Rimini, Italy

**Background:** PML, caused by polyomavirus JC (JCV), remains a severe opportunistic disease in HIV-infected patients. Detection of JCV-DNA in plasma and peripheral leukocytes has been reported in immunocompromised subjects, with or without PML, but it was neither regarded as a sensitive and specific diagnostic marker of PML. Moreover, it is not known whether it can be considered as a marker of more aggressive PML course. The aim of this study was to assess the diagnostic and prognostic significance of JCV-DNA levels in plasma at PML onset on clinical outcome.

**Methodology:** This is a cross-sectional, retrospective, multicentre study of 79 patients with HIV-related PML and 49 HIV positive controls whose plasma samples were collected within 90 days from onset of symptoms and available for virological analysis. Patients were enrolled in Italy between 1993 and 2012. PML diagnosis was confirmed by JCV-DNA detection in CSF in 68 cases, at autopsy in 2 cases, or based on typical clinical and radiological features in 9 cases. Associations between categorical measures were assessed by the Fisher’s exact test. The effect of a number of factors on time from onset of symptoms to the end of follow-up due to progressive disease or death was assessed by Kaplan-Meier and Cox proportional-hazard models.

**Results:** Sixteen/79 patients (20.3%) were female and 63 (79.7%) male. Median (IQR) age was 38 years (34-43.5). CD4+ were 80 (38-220) cells/μL, plasma HIV-RNA was 3.87 (1.69-4.98) log10 copies/mL at the time of PML and 59/79 (74%) were exposed to combined antiretroviral treatment (cART). Fifteen patients showed contrast enhancement at magnetic resonance imaging, 12 experienced immune reconstitution inflammatory syndrome (IRIS), and 10 received high-dose steroids. JCV-DNA was detected in plasma of 4/49 (0.1%) control subjects and of 29/79 (36%) PML patients. The sensitivity and specificity of the presence of JCV-DNA in plasma was 36.7% and 91.8%, respectively. The only independent factor associated with JCV-DNA detection in plasma was JCV-DNA in CSF. The occurrence of IRIS was associated with more favourable clinical outcome. cART therapy was associated with an 8-fold reduction in the hazard of progression or death among patients without JCV-DNA in the plasma (p=0.003) but only a 3-fold reduction among patients with JCV-DNA in plasma (p=0.005) and patients with JCV-DNA in CSF (p=0.012).

**Conclusions:** Detection of JCV-DNA in plasma has low sensitivity but high specificity in PML diagnosis. Presence of JCV-DNA in plasma is associated with a less favorable clinical outcome in patients with PML. Although cART is associated with dramatic reductions in the hazard of progression or death from PML, its effect is attenuated when JCV-DNA is not suppressed in plasma.
470  CD4-Independent Infection in the CNS of R5 SHIV+ Macaques Is Associated With Severe Neuropathology

Ana Rachel Leda1, 2, Ke Zhuang, Lily Tsai, Agegnehu Gettie1, Heather Knight1, Carole Harbison3, Susan Westmoreland4, Cecilia Cheng-Mayer1
1Aaron Diamond AIDS Research Center, New York, NY, United States, 2Federal University of Sao Paulo, Sao Paulo, Brazil, 3New England Primate Research Center, Southborough, MA, United States

Background: HIV infection of mononuclear phagocytes in the CNS is the main driving force of HIV-associated encephalitis (HIVE). Neurotropism is primarily determined by the env gene, which seems to evolve independently in this anatomic region. The emergence of highly macrophage-tropic viral strains that engage CD4 and CCR5 receptors differently or require little or no CD4 for entry has been reported in HIV and SIV infection of the brain, and appears to be the main selective pressure in this compartment. Here we aimed to characterize Env variants within the brain of R5 SHIV-infected macaques with giant cell encephalitis (SHIVE) to determine the phenotypes associated with neurologic disease spectrum.

Methodology: Samples from the CSF, blood and brain were collected at the time of necropsy from five encephalitic animals infected with R5 SHIV-B and two encephalitic animals infected with SHIV-C. Full-length envelope glycoprotein gp160 (env) was obtained by single genome amplification (SGA) or bulk PCR. Phylogenetic analyses were performed to genotypically characterize the variants, and single round replication competent viruses were generated and assessed for infection of CD4low cells and CD4negative cells. Moreover, brain tissue sections were pathologically analyzed using in situ hybridization and immunohistochemical techniques.

Results: Phylogenetic analysis of env gp120 V3-V5 sequences obtained from the CSF and plasma of the SHIVE animals showed a correlation between lack of viral compartmentalization and severity of neuropathology. Furthermore, Envs isolated from animals with the most severe lesions showed an increased ability to infect primary macrophages and CD4low cells. Histologic examination showed that compared to animals presenting milder forms of CNS pathology, animals with severe and extensive lesions had the most pronounced macrophage/microglial activation and the strongest SIV in situ labeling in resident microglia and astrocytes. In agreement with these findings, the ability of viral infection in the absence of CD4 was more readily detected in the brain and CSF compartments of the animals with severe encephalitis.

Conclusions: The severity of neuropathological changes is associated with macrophage tropism of Envs from the CNS, and further evolution to CD4-independence and infection of resident microglia and astrocytes. The R5 subtype B and C SHIVE macaques on which this study was based provide a new and robust model to further our understanding the role of the HIV envelope in neuropathology and residual virus in the CNS, providing information that should guide efforts toward eradicating HIV from the body.

471  HIV-Associated Neurocognitive Disorder Is Associated With HIV-1 Dual Infection

Gabriel A. Wagner1, Antoine Chillon2, Donald R. Franklin3, Gemma Caballero4, Sergei L. Kosakovsky Pond5, Robert K. Heaton2, Douglas D. Richman2, Davey M. Smith2, 3, 5, CARTher Group
1Infectious Diseases, University of California San Diego, La Jolla, CA, United States, 2University of California San Diego, La Jolla, CA, United States, 3Veterans Affairs San Diego Healthcare System, San Diego, CA, United States

Background: HIV-1 dual infection (DI) has been associated with decreased CD4 T-cell counts and increased viral loads. The same markers are also associated with the development of HIV-associated neurocognitive disorder (HAND), which continues to be a prevalent and debilitating problem among HIV-infected individuals in the era of antiretroviral therapy (ART). Despite this, the neurological sequelae of DI are poorly characterized. We used next-generation sequencing (NGS) to measure the prevalence of DI among ART-suppressed CARTher cohort participants, and examine the relationship between HAND and DI.

Methodology: CARTher cohort participants were selected who had > 4 years of follow-up and were suppressed on ART (N=34). NGS (454 FLX Titanium, Roche) was performed on PBMC-derived HIV-1 DNA populations using four PCR-amplified coding regions (env C2-V3, gag p24, pol RT, and pol PR). Samples were classified as DI when (i) maximal genetic diversity exceeded previously optimized thresholds, (ii) phylogenetic reconstruction showed two divergent populations supported with bootstrap values >95%, and (iii) local BLAST ruled out contamination with in-house strains. All study participants underwent neurocognitive, substance use, and neuromedical measurements at each study visit. A global deficit score indicative of HAND was derived from a comprehensive battery of neuropsychological tests adjusted for demographics and corrected for practice effect over time. Participants with comorbidities confounding HAND were excluded.

Results: Of 34 participants, 21 (62%) remained neurocognitively normal throughout the study period and 13 (38%) showed varied degrees of impairment. In univariate analyses, timepoints with HAND were associated with lower CD4 T-cell counts and with a shorter estimated duration of infection (p < 0.05). Despite ART, 27 participants had detectable HIV viral loads, but these levels were not significantly different between the normal and impaired groups (p = 0.866). Nine study participants had evidence of DI in at least one HIV coding region [prevalence of 26.5%, 95%CI 13.8%–43.1%]. Among the 13 participants with HAND, 7 (54%) had DI in at least one timepoint, while 2 out of 21 (9.5%) neurocognitively normal participants had evidence of DI (p < 0.05).
Conclusions: Using NGS, we identified a high (26.5%) prevalence of DI in a population of virally suppressed HIV-infected individuals. The presence of neurocognitive impairment was associated with DI, lower CD4 counts and with shorter duration of infection. These data suggest that DI may play an important role in the development of HAND among at-risk infected individuals, perhaps due to increased viral diversity, although the elucidation of proximate causes will require further investigation.

472 Single Genome Analysis Reveals Genetic Characteristics of Neuroadaptation Across HIV-1 Envelope
Teresa H. Evering, Leslie St. Bernard, Charles Farmer, Martin Markowitz
The Aaron Diamond AIDS Research Center, New York, NY, United States

Background: The prevalence of HIV-1 associated neurocognitive disorders (HANDs) has been estimated to be 45-50% in the CHARTER study. In the cART era, this disease burden is largely represented by asymptomatic and mild neurocognitive disease (ANI and MND). We hypothesized that detailed analyses of full-length HIV-1 env (>2.5Kb) would allow for the identification of genetic characteristics associated with the presence of viral variants in the CNS.

Methodology: We used single genome amplification to generate full-length HIV-1 env clade B variants from the paired CSF and plasma samples of 15 chronically infected HIV+ subjects from CHARTER with no neurocognitive impairment (NCI) (N=6), ANI (N=7) and MND (N=2). Subjects were viremic and either treatment naive (N=8) or experienced (N=7). We used phylogenetic analyses to determine viral compartmentalization, potential N-linked glycosylation sites (PNLGS) and genetic diversity. We identified patterns of compartmentalization with the Viral Epidemiology Signature Pattern Analysis software and the CorMut package was used to detect correlated mutations.

Results: We analyzed 717 confirmed single genome sequences (SGS) and found that various degrees of compartmentalization exist across disease states and histories of cART utilization. In individuals with compartmentalized virus, mean HIV-1 env diversity was lower in CSF- than in plasma-derived variants ($p=0.04$). Mean V1V2 loop length was shorter and the mean number of PNLGS was lower in CSF-derived variants compared to their paired plasma counterparts ($p=0.01$ and $p=0.04$). The correlation between V1V2 loop length and number of PNLGS in CSF variants was significant ($p=0.02$, $r^2=0.34$). Mean viral diversity (CSF + plasma) and V1V2 length (CSF) did not differ significantly between individuals without NCI and those with ANI or MND ($p>0.05$ for all comparisons). In individual phylogenies, we identified HIV-1 env positions where the dominant amino-acid differs significantly between CSF and plasma quasispecies in both variable and constant regions of gp120 as well as in gp41 (Bonferroni corrected $p<2.7\times10^{-4}$). Comparing positions across individuals, we identified 25 compartmentalization hotspots across the env gene. These include the previously identified HXB2 gp160 position 308 (V3 13), as well novel positions at 463 (V5 4) and 641 (gp41 130). Correlated mutation analyses reveal that a subset of the amino-acid residues in these positions form a network of significant correlations, with mutual information scores $>0.1$.

Conclusions: Detailed analyses of SGS-derived full length env from subjects with the most common HAND diagnoses in the cART era allowed us to confirm and extend current knowledge of the genetic characteristics associated with HIV-1 env neuroadaptation.

ART Effects On HAND and CNS Reservoirs

473 HIV-1 Replication in Central Nervous System Increases Over Time On Protease Inhibitor Only Therapy
Christoph Stephan1, Maximilian Donath1, Timo Wolf1, Annette Haberl1, Markus Bickel1, Siri Göpel1, Pavel Khaykin1, Annemarie Berger2, Dimitria Bon3, Reinhard Brodt1
1Infectious Diseases, Goethe-University Hospital, Frankfurt, Germany, 2Medical Virology Institute, Goethe-University Hospital, Frankfurt, Germany, 3Biomathematics, Goethe-University Hospital, Frankfurt, Germany

Background: Class sparing antiretroviral therapy with only protease inhibitors (PI) had been associated with central nervous system (CNS)-replication of HIV-1, probably due to impaired CNS penetration-effectiveness, but clinical confirmation is scarce.

Objective was to evaluate risk factors for CNS replication of HIV-1 in patients on only boosted PI, versus nucleoside reverse transcriptase inhibitor (NRTI)-containing triple therapy.

Methodology: Retrospective case-control study (1:5-ratio), with patients from a large German HIV-treatment unit, data were collected from 2005-2013. All patients with available data on antiretroviral therapy, clinical and demographic characteristics, and paired results from simultaneous HIV-1 load-assessments in cerebrospinal fluid (CSF) and blood plasma, were eligible. CSF was collected for various reasons, patients were both...
neurologically symptomatic, or asymptomatic. A virus-load (VL)-ratio for CSF/blood-quotient was built, and patients were evaluated according to treatment with either only boosted PI (cases), or NRTI-containing triple therapy (controls). Univariate group statistics and Pearson’s regression analysis for time-dependent results for PI-patients were generated.

Results: 155 patients were evaluated: 24 cases and 131 controls. All cases used boosted double PI-regimens, consisting of saquinavir (21), lopinavir (20), atazanavir (4), fosamprenavir (2) and indinavir (1), respectively. At time of CSF collection, the mean age was 47 years (y), 22% were female, time from first HIV-diagnosis was 10.2y (cases 15.7 vs controls 9.2, p≤0.001), the mean number of regimens was 7.39 for cases and 4.24 for controls (p=0.002), and median CD4 count were 186/mm3, or 162/mm3 (n.s.). The proportion of patients with undetectable HIV-1 in CSF was 25% for cases and 49.6% for controls (p=0.026) whereas in blood 46% vs. 41% (n.s.). Median CSF-VL was 600 cop/mL for cases, and 50 cop/mL in controls (p=0.027); median VL from blood was 115cop/mL, or 173cop/mL (n.s.). Mean VL-ratio was 342.91 for cases and 54.48 for controls (p=0.002). Pearson’s regression analysis showed an increasing trend for VL-ratio over time for cases (see figure).

Conclusions: In this unselected cohort, HIV-1 replication in CSF was higher for patients on only PI, than for those on NRTI-containing triple therapy, supporting a worse CNS-penetration effectiveness for used PI. Patients’ over time rise in CNS-viral replication suggests that this effect was time-dependent.

Tanja Su1, Judith Schouten2, 3, Gert J. Geurtsen2, Ferdinand W. Witt4, 5, Inke G. Stolte5, Peter Portegies2, 6, Charles B. Majoie1, Ben A. Schmand2, 7, on behalf of the AGEhIV Cohort Study Group
1Radiology, Academic Medical Center, Amsterdam, Netherlands; 2Neurology, Academic Medical Center, Amsterdam, Netherlands; 3Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands; 4Internal Medicine, Academic Medical Center, Amsterdam, Netherlands; 5GGD Amsterdam, Amsterdam, Netherlands; 6Neurology, Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands; 7Psychology, University of Amsterdam, Amsterdam, Netherlands

Background: The commonly used published Frascati criteria likely overestimate HIV-associated neurocognitive disorder (HAND) prevalence. Modified criteria proposed by Gisslèn attempt to reduce sensitivity while retaining specificity. Multivariate normative comparison (MNC), specifically designed to control for false-positive rate while retaining sensitivity, is a novel and potentially more accurate technique for evaluating cognitive impairment (CI).

Methodology: 103 HIV-infected men with suppressed viraemia on cART for ≥12 months and 75 uninfected male controls (comparable regarding age, ethnicity, IQ and education), all aged ≥45 and participating in the AGEhIV cohort study, underwent neuropsychological assessment (covering fluency, attention, information processing speed, executive function, memory and fine motor function). Frascati and Gisslèn criteria were applied to detect HAND. Next, MNC was used to compare all test scores of each HIV-positive individual against the distribution of test scores of the total control group. MNC uses Hotelling’s T2 to statistically compare multiple characteristics of an individual against the distributions of the same characteristics in a control group taking the covariance between all characteristics into account. The false positive rate (alpha, which is selectable at any percentage) was set at 5% one-tailed, providing a specificity of at least 95%.

Results: HIV-positive men as a group performed worse compared to uninfected controls on all domains tested, although differences were not statistically significant.

Applying Frascati criteria, HAND was present in 49 HIV-positive (48%) but also in 31 uninfected men (41%) (p=0.41), and by Gisslèn’s criteria in 15 HIV-positive (15%) and 7 uninfected men (9%) (p=0.30). Using MNC, CI was detected in 32 HIV-positive men (31%) (Table).

Conclusions: Cognitive impairment by Frascati criteria was highly prevalent in HIV-positive but nearly equally so in uninfected men, confirming low specificity of this method. Although HAND prevalence was reduced applying Gisslèn’s criteria, it remained nearly as prevalent among uninfected controls, indicating improved sensitivity but continued low specificity. Applying MNC with its low false-positive rate provided a more accurate estimate of HIV-associated cognitive impairment of approximately 30 percent in HIV-infected men with suppressed viraemia on cART.

Improvement of Depression and Anxiety After Discontinuation of Long-Term Efavirenz Treatment
Khutso M. Mothapo, Arnt Schellekens, Reinout van Crevel, Karin Grintjes-Huisman, Monique Keuter, Peter Koopmans, Andre van der Ven
1Internal Medicine and Nijmegen Institute for Infection, Inflammation and Immunity, Radboud University Medical Center, Nijmegen, Netherlands; 2Psychiatry, Radboud University Medical Center, Nijmegen, Netherlands

Background: Efavirenz is part of first-line antiretroviral therapy guidelines of WHO since 2002. The side effects of efavirenz are mainly neuropsychiatric and generally considered to be mild and transient. Recent studies indicate however that discontinuation of chronic efavirenz treatment can be observed in up to 50% of cases, possibly related to long term neuropsychiatric side-effects. The aim of this study was to 1) assess neuropsychiatric symptoms in HIV-infected patients on long-term efavirenz therapy and 2) study the effect of a switch to a non-retroviral treatment on neuropsychiatric symptoms.

Methodology: In an observational clinical trial, 47 HIV-infected participants on long-term efavirenz treatment were included with suppressed viral loads and high CD4 cell counts. 23 reported signs and symptoms (mainly neuropsychiatric symptoms or physical complaints) and 24 asymptomatic patients were included as controls. All participants completed three self-report questionnaires on neuropsychiatric symptoms.

All symptomatic patients were switched to a non-efavirenz containing regimen and were retested 2 week and 3 months after switching. The depression-anxiety-stress-scale (DASS) was used to assess anxiety, depression and stress, the symptom-checklist (SCL-90) to assess a variety of neuropsychiatric symptoms and the outcome-questionnaire (OQ-45) to assess daily life functioning. Data were analyzed using multivariate ANOVA for baseline group comparisons and repeated measures ANOVA to analyze any change in the group of switchers over time. Linear regression was used to analyze prediction of symptom change after switching.

Results: Neuropsychiatric symptoms were common among HIV-infected patients on long-term efavirenz therapy, mainly being depression, anxiety, stress, insufficiency in thinking and paranoia. After switching, these symptoms improved significantly to near normal levels. These effects were most prominent for depression, anxiety and stress symptoms (using DASS and SCL-90). Improvement in neuropsychiatric symptoms was best predicted by high baseline symptoms, using the SCL-90.

Conclusions: Neuropsychiatric symptoms are common among HIV-infected subjects and may be caused by different factors/agents, including long-term efavirenz use. Neuropsychiatric assessment, the SCL-90 in particular, could identify those that may benefit most from the discontinuation of efavirenz.

New Advanced EEG Technique To Monitor Early Brain Damage in Naïve HIV and Its Recovery During ART
Massimo Andreoni, Claudio Babiloni, Paolo Maria Rossini, Paolo Onorati, Stefano Ferracuti, Francesco Di Campli, Antonio Acati, Elisabetta Teti, Alfredo Pennica
1Clinical Infectious Diseases, Tor Vergata University, Rome, Italy; 2Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Italy; 3Department of Neuroscience, San Raffaele Pisana, Rome, Italy; 4Institute of Neurology - Department of Geriatrics, Catholic University Sacro Cuore, Rome, Italy; 5Physiology and Pharmacology, Sapienza University of Rome, Rome, Italy; 6Psychiatry, Sapienza University of Rome - S. Andrea Hospital, Rome, Italy; 7Clinical Infectious Diseases, Sapienza University of Rome - S. Andrea Hospital, Rome, Italy

Background: HIV patients may show a wide spectrum of cognitive deficits from mild forms up to dementia demonstrable with neuropsychological tests; however earlier deficits can be hidden for years by brain neuroplasticity and these result in an absence of symptoms. Cognitive impairment is typically accompanied by a pathological increase of EEG rhythms at frequencies <4 Hz (delta) and by a decrease of dominant rhythms at 8-12 Hz (alpha). We demonstrate that these EEG rhythms are abnormal in asymptomatic naïve HIV subjects and show recovery under antiretroviral therapy.

EEG rhythms improvement during ART.
T0: baseline; T1: after 4 weeks of ART; T2: after 8 weeks of ART; T5: after 20 weeks of ART.
CSF Biomarker Profile in HIV Patients With and Without CSF Viral Escape
Ignacio Pérez-Valero1, Scott Letendre2, Robert Heaton3, Ronald Ellis2, Allen McCutchan1, David Simpson3, Reena Deutsch1, Igor Grant1, And the CHARTER Group

1Hospital Universitario La Paz, Madrid, Spain, 2University of California, San Diego, CA, United States, 3University of California San Diego, San Diego, CA, United States, 4Mount Sinai Hospital, New York, NY, United States, 5Mount Sinai School of Medicine, New York, NY, United States

Background: The association between levels of inflammatory biomarkers and CSF Viral Escape (CVE) is unexplored.

Methodology: Cross-sectional analysis performed to compare levels of inflammatory biomarkers in patients with and without CVE (HIV-RNA >50cop/mL in CSF and <50cop/mL in plasma). Individuals followed in two large HIV Cohorts, tested for CSF and blood biomarkers of immune activation (CXCL10, IL6, TNF-Alpha, MCP-1 and WBC) were included. Blood and CSF biomarkers along with demographics and HIV-related clinical data of patients with and without CVE were compared using multivariable logistic regression.

Results: 296 patients were evaluated: Mean age 46.6 years, 58% Caucasian, 87% male with a mean time of HIV-infection of 12.4 years and median CD4 nadir of 110 cells. CSF Viral Escape was detected in 8 patients (2.7%). Subjects' characteristics were similar, regardless of CVE status, except for a longer HIV-infection (mean time 17.4 vs. 12.3 years; p=0.049) and a lower CD4 nadir (median 12 vs. 115 cells; p=0.038) associated with CVE. Median CSF CXCL10 levels were higher (8416 vs. 2771; p=0.011) while median plasma IL-6 levels were lower (1.56 vs. 2.97; p=0.049) in presence of CVE. Proportion of patients presenting CSF WBC pleocytosis was also higher (50% vs. 12.3%; p=0.002) in the CVE group. After logistic regression analysis, CXCL10 was the unique factor that remained independently associated with CVE (p<0.001).

Conclusions: CSF CXCL10 is elevated in patients with CVE, implying higher immune-activation and inflammation in their CNS, but our cross-sectional study cannot distinguish if these elevated levels are a cause or effect of CVE.
**Determinants of Cognitive Impairment in HIV-Positive Men On cART and Uninfected Controls**

Judith Schouten1,2, Tanja Su3, Ferdinand W. Wit4, Neeltje A. Kootstra3, Matthew W. A. Caan3, Gert J. Geurtsen1, Ben A. Schmand4, Charles B. Majoe4, Peter Portegies5,7, Peter Reiss1,4, on behalf of the AGEhIV Cohort Study Group

1Neurology, Academic Medical Center, Amsterdam, Netherlands, 2Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, 3Radiology, Academic Medical Center, Amsterdam, Netherlands, 4Internal Medicine, Academic Medical Center, Amsterdam, Netherlands, 5Experimental Immunology, Academic Medical Center, Amsterdam, Netherlands, 6Psychology, University of Amsterdam, Amsterdam, Netherlands, 7Neurology, Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands

**Background:** HIV-positive individuals may be at increased risk of cognitive impairment (CI). The contribution of HIV-, antiretroviral treatment- and non-HIV-related risk factors towards CI remains to be clarified further.

**Methodology:** 103 HIV-infected men with suppressed viraemia on cART for ≥12 months and 75 uninfected male controls (comparable regarding age, ethnicity, IQ and education), all aged ≥45 and participating in the AGEhIV cohort study, underwent neuropsychological assessment (covering fluency, attention, information processing speed, executive function, memory and fine motor function). CI was assessed using Frascati criteria and by multivariate normative comparison (MNC), a novel and more accurate technique for evaluating cognitive impairment (CI). MNC was used to compare all cognitive test scores jointly from each HIV-positive individual with the distribution of scores from the total uninfected control group. The false positive rate (alpha) was set at 5% one-tailed, providing a specificity of at least 95%. Multiple logistic regression was used to identify determinants for CI.

**Results:** The numbers of participants with CI in each group using either Frascati criteria or MNC are shown in the Table. Adjusting for age, education and native language, depressive symptoms remained borderline significantly associated with CI by both methods, whereas HIV-status did not.

In HIV-positive men after adjusting for the same parameters, depressive symptoms, years spent with CD4 counts <350 cells/μL and higher soluble CD163 levels, were independently associated with CI, both by Frascati criteria and MNC. A lower central nervous system penetration effectiveness (CPE) score was independently associated with CI, but only when applying Frascati criteria.

Risk factors that were not significantly associated with CI are listed in the Table.

**Conclusions:** The presence of depressive symptoms was associated with cognitive impairment, and in HIV-infected men with suppressed viraemia on cART, together with a longer time spent with reduced CD4 counts and evidence of increased innate immune activation contributed to the risk of CI, regardless of the method by which CI was assessed. The contribution of the CPE score was less consistent.

ANI=asymptomatic neurocognitive impairment
MND=mild neurocognitive disorder
HAD=HIV-associated dementia
# False positive rate (alpha) set at 5% one-tailed, thus specificity was at least 95%.
* Models adjusted for age, education and native language.
^ MNC: logistic regression possible only on the HIV+ group.

The following risk factors were not significantly associated with CI:

Intoxications: Cannabis/cocaine/ecstasy, alcohol, prior IV drug use.
Cardiovascular risk factors: Hypertension, diabetes, smoking, BMI, waist-hip ratio, waist circumference, prior cardiovascular disease (myocardial infarction, angina pectoris, stroke or peripheral arterial insufficiency), dyslipidemia (including total chol, LDL, HDL and triglycerides), lipoprotein(a), lipid lowering medication, positive family history for myocardial infarction.
Inflammatory markers: C-reactive protein, D-dimer, soluble CD14.
HIV-specific factors: Duration of HIV-infection, duration of ART use, mean CD4 count during the year prior to enrolment, years with CD4 <200/100 cells/mm³, years spent with a(n) (un)detectable plasma viral load, AIDS, current/prior/cumulative duration of efavirenz use.
484 Differences Between Cerebrospinal Fluid and Blood Biomarkers of Inflammation in HIV Infection

Julia Peterson1, Sheila Keating2, Dietmar Fuchs3, Phillip Norris4, Henrik Zetterberg4, Barbara Shackle4, Serena Spudich6, Magnus Gisslen4, Richard W. Price1
1Neurology, University of California San Francisco, San Francisco, CA, United States, 2Blood Systems Research Institute, San Francisco, CA, United States, 3Center for Chemistry and Biomedicine, Innsbruck Medical University, Innsbruck, Austria, 4Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, 5University of California Davis, Davis, CA, United States, 6Neurology, Yale University, New Haven, CT, United States

Background: HIV central nervous system (CNS) infection is associated with local inflammation that evolves over the course of systemic disease and impacts neurological function. To compare CNS and systemic inflammation, we assessed 10 inflammatory biomarkers in cerebrospinal fluid (CSF) and blood across a spectrum of subject groups.

Methodology: This exploratory cross-sectional study measured 10 inflammatory biomarkers (TNF-α, MMP-9, CXCL10, sCD14, sCD163, sVCAM, CCL2, IL-6, TIMP-1 and neopterin) by EIA in 9 subject groups: HIV uninfected controls (HIV-, N=20); primary HIV infection (PHI, 24); untreated, virally-suppressed (Rx, 19) and elite controllers (EC, 8). Exploratory analysis applied nonparametric methods to determine the nosology of inflammation and neurodegeneration in HIV patients on suppressive cART.

Results: Among study subjects who consented to lumbar punctures (11 of 15 participants) we found no significant change from baseline to the final panobinostat treatment week neither in biomarkers of neurodegeneration (total tau, phosphorylated tau, soluble amyloid-β) nor in biomarkers of neuroinflammation (CRP, soluble CD14, soluble CD163, neopterin, monocyte chemotactic protein-1 (MCP-1), interferon-γ induced protein-10 (IP-10), macrophage inflammatory protein-1α (MIP1-α), matrix metalloproteinase-9 (MMP-9)).

Conclusions: Repeated, cyclic treatment with the HDACi panobinostat was not associated with CNS adverse effects as measured by CSF biomarkers of inflammation and neurodegeneration in HIV patients on suppressive cART.
486LB Neuroinflammation in Asymptomatic HIV-Infected Subjects On Effective cART
Jaime H. Vera1, Qi Guo2, Ilan Rabiner3, Paul Matthews4, Roger Gunn5, Alan Winston1
1Infectious Diseases, Imperial College London, London, United Kingdom, 2Institute of Psychiatry, King’s College London, London, United Kingdom, 3Imanova Centre for Imaging Sciences, London, United Kingdom, 4Division of Brain Sciences, Imperial College London, London, United Kingdom

Background: Neuroinflammation may contribute to the pathogenesis of HIV-associated cognitive impairment. We undertook cerebral PET imaging using the 18kDA translocator protein TSPO radioligand [11C]PBR28 to assess neuroinflammation in treated HIV-infected subjects without neurological symptoms

Methodology: Cognitively healthy, neurologically asymptomatic HIV-infected subjects (cases) on effective combination antiretroviral therapy (viral load <50 copies/mL) and HIV-negative individuals (controls) underwent a cerebral PET scan with [11C]PBR28. Cases had neuropsychological testing and assessment of cerebral metabolites using proton-magnetic resonance spectroscopy ([1H] MRS) in the right basal ganglia (RBG). TSPO binding affinity was assessed with both high affinity (HABs) and mixed affinity (MABs) binders eligible. A two tissue compartmental model was used to estimate the total volume of distribution (VT) and distribution volume ratios (DVR) in regions of interest (ROIs) including brain stem, basal ganglia and cortical regions in each subject. Differences between groups were assessed using ANOVA and relationships between HIV clinical markers and VT were explored by correlation analyses

Results: 8 HABs, and 4 MABs cases (n=12), mean age (SD) 42.7 (6.4) years and 6 HABs and 4 MABs age-matched controls (n=10), mean age 41.6 (8.6) years were enrolled. Cases had a median (range) CD4 count of 645(350-1240) cells/μL and nadir CD4 count of 196(70-350) cells/μL. The median (range) pre-treatment plasma HIV-RNA of 128639 copies/mL(151 to 1624782). There was a global increase in the mean VT in cases compared to controls with significant increase in VT in the basal ganglia based on the parametric analysis after multiple comparisons correction (p<0.01). Significant local increases in DVR were found in the parietal cortex (p<0.01) and globus pallidus (p=0.035) In HIV cases, despite cognitive function being intact, after controlling for age and education, significant negative associations between [11C]PBR28 binding and performance on both visual learning and working memory tasks were observed in the basal ganglia (p=0.018) and parietal cortex (p=0.025). Greater [11C]PBR28 binding in the basal ganglia also was associated with both a higher RBG brain myo-inositol/creatine ratio (a marker of glial inflammation) as evaluated by MRS (p=0.011) and greater pre-treatment plasma viral load (p=0.029). Associations between VT in brain regions and other HIV clinical parameters (including nadir CD4 count, p=>0.1)were not observed

Conclusions: Evidence of neuroinflammation on cerebral PET is present in neuro-asymptomatic HIV-infected individuals despite effective control of plasma viraemia and is associated with greater pre-treatment viral load but not nadir CD4 count

487 CSF Biomarkers Correlate With Magnetic Resonance Spectroscopy Metabolites During HIV Disease
Albert M. Anderson1, Christine Ferronella-Notestine2, Anya Unlauf2, David Clifford3, Christina Marna4, Benjamin Gelman4, Justin McArthur2, Allen McCutchan5, Susan Morgello1, Scott Letendre1, for the CHARTER group
1Emory University School of Medicine, Atlanta, GA, United States, 2University of California-San Diego, San Diego, CA, United States, 3Washington University at St. Louis, St. Louis, MO, United States, 4University of Washington, Seattle, WA, United States, 5University of Texas Medical Branch, Galveston, TX, United States

Background: HIV-associated neurocognitive disorders (HAND) persist in the cART era. These disorders adversely affect quality of life, work ability, and overall survival. Persistent immune activation appears to contribute to the pathology of HAND and evidence exists that biomarkers of immune activation correlate with cerebral metabolites measured by magnetic resonance spectroscopy (MRS). The purpose of this analysis was to determine associations between cerebrospinal fluid (CSF) biomarkers and regional cerebral metabolites in a multicenter cohort.

Methodology: Data from 91 participants were analyzed from five sites in the US (Galveston, Baltimore, New York, Seattle, and San Diego) as part of the CHARTER study. MRS concentrations of N-acetylaspartate (NAA), choline (Cho), myo-inositol (MI), and creatine (Cr) were quantified using LCModel in frontal white matter (FWM), frontal gray matter (FGM), and basal ganglia (BG). CSF biomarkers were measured by immunoassay. Multivariable mixed effects models accounted for demographic and disease characteristics as well as proportion of relevant tissue volume within each voxel.

Results: Participants were mostly middle-aged (median age 44) men (84%) on ART (76%). 47% were European-American and 43% African-American. Other median values were: current CD4+ count 458/mm³ (IQR 311-600), nadir CD4+ count 145/mm³ (IQR 24-238), log10 HIV RNA 1.72 (plasma) and 1.7 (CSF). 26% were hepatitis C seropositive. Higher (↑) levels of MCP-1 and IP-10 were each associated with ↑levels of MI and Cr in FWM (see Table for adjusted R² and p value). A particularly strong association was found between ↑MCP-1 and ↑Cho in BG while a weaker association was found between ↑IP-10 and ↑NAA in FWM. No statistically significant associations were present for sCD14 and SDF-1α.

Conclusions: In this cross-sectional analysis of HIV infected individuals from multiple sites, two CSF biomarkers were associated with cerebral metabolites reflecting energy metabolism, membrane remodeling, neuronal integrity, and glial proliferation. The biomarkers are indicators of monocyte chemotaxis (MCP-1) and antiviral immune responses (IP-10). While Cr was not used as a denominator for metabolite-biomarker associations as in previous studies, the unexpected positive association between IP-10 and FWM NAA warrants further
investigation. Frontal white matter was the most commonly involved brain region, which may reflect the impact of immune activation on myelin and axonal integrity.

488 Abdominal Obesity, Inflammation, Immune Activation and Neurocognitive Impairment
